In the 300 to 550 c.c. class the only competitor rode an Indian, and in the 300 c.c. class there was likewise only one—a rider of a Baby Triumph. Florencio Fuentes was the winner of the open solo class, with an average speed over the whole distance of 38½ m.p.h. Luis Coppel, who won the open sidecar class, finished the course with an average of 35 m.p.h. The fastest lap time was made by the second rider, Manolo Fuentes, 1h. 27m. 11⅘s. for approximately ninety-four kilometres, which works out at about 40 m.p.h. The fastest lap on a sidecar was that of the third man in this class, José Alvarez, viz., 1h. 34m. 25⅘s., which equals a speed of about 37 m.p.h.

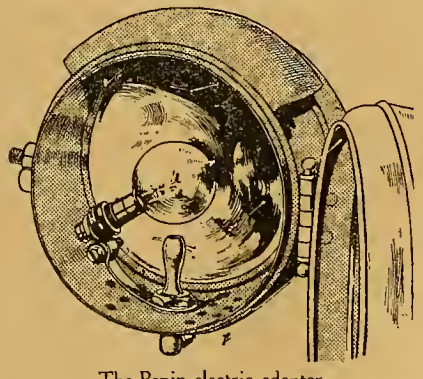
The accompanying photograph shows one of the worst bends on the course, also the rough state of the road surface and the stiff gradient at the bend.

Inset are pictures of the winners of the solo and sidecar classes on their Harley-Davidson machines taken at two different points of the circuit.

To Convert Gas Lamps to Electric.

THE ever-increasing popularity of electricity for lighting purposes on motor cycles no doubt augurs that eventually electric lamps will be the rule rather than the exception. In the meantime, large numbers of owners of gas lamps will convert them, and in this connection the little fitment illustrated will be of interest.

Although very simple in construction, the Papin adapter has several important advantages to recommend it. It consists of a flat steel arm drilled at one end to be fixed by the nut holding the burner, from which point it may be swivelled as desired to adjust the focus. On its outer end it is dished to hold an ordinary small lamp holder, and also is so shaped that it may be used to hold the gas burner, if this is carried. The patentee of the device is Mr. G. H. Papin, 59, Kingsway, Coventry.



The Papin electric adapter.

British Wins in France.

Greame Fenton, riding an A.B.C., won no less than six prizes in a hill-climb recently held at Mont Ventoux, his total wins in this one event being: 500 c.c. solo class, first on formula, second on time; 750 c.c. solo class, first on time; 1,000 c.c. solo class, second on time; stopping and restarting test, first; general classification on formula, first. The A.B.C. machine he rode was made by the French Gnôme and le Rhône Company, so that it cannot be described as all-British; but British brains are responsible for it.

Times to Light Lamps.

GREENWICH TIME.

Oct. 23rd	...	...	5.20 p.m.
,, 25th	...	...	5.16 ,,
,, 27th	...	...	5.13 ,,
,, 29th	...	...	5.9 ,,

What's in a Name?

The following little gem appeared in a recent number of a Welsh provincial paper: "3½ Premier, white and poppy, single-speed, £18."

The Ubiquity of "The Motor Cycle."

The Motor Cycle has appeared on the stage. True it was only carried by one of a crowd in a street scene in a Vaudeville sketch, but it served its purpose in making the setting real.

Police Trap.

We are informed that a police trap is in operation on the Duffield Road, Derby. It commences at Highfield Road and finishes at Belper Road (Five Lamps), where a constable is hidden in a doctor's garden. Heavy fines have been inflicted. Derby is also applying for a 10 m.p.h. limit.

Sheepshead Bay Race Meeting.

At the motor cycle race meeting at Sheepshead Bay the American championship was won by Eugene Walker on an Indian.

The other races resulted as follow: Two miles race.—First, Otto Walker (Harley-Davidson). Fifty miles race.—First, Ray Wishaar (Harley-Davidson). Hundred miles race.—First, Albert Burns (Harley-Davidson).

A New Company.

A new company under the title of Middlemores (Coventry), Ltd., has been registered to take over the whole of the assets of the Coventry branch of Middlemore and Lamplugh, Ltd., who are in voluntary liquidation. Liabilities of the old company will be discharged in full. Middlemores (Coventry), Ltd., is a private limited company, and Mr. W. A. De Lattre, who has had sole control of the Coventry business, is still retained as managing director with a seat on the Board, and, associated with him are Mr. H. J. Mason, managing director of D. Mason and Sons, Ltd., of Birmingham and Wolverhampton, saddlery and harness manufacturers; Mr. J. H. Bromielow, engineer, formerly of Kynochs, and Mr. Alf. Bednell, whose name needs no introduction to the cycle and motor cycle trades.

Self-Sealing Rubber Co.

The directors of the above company recommend a dividend of 15% free of income tax to be paid for the year ending August, 1919.

French Kilometre Record Attempts.

The Automobile Club of France held flying kilometre races, and kilometre races with a standing start, on the Achères road last Monday. The events were open to motor cycles and cars.

Italian Road Race.

Suisini, riding a Rudge, beat all comers in the 500 c.c. class of the Toscane motor cycle race in Italy, on the 28th ult. The distance was about 143 miles, and the time 5h. 35m. 16s. In the 1,100 c.c. class, Harley-Davidsons were first and third and an Indian second.

Stolen Motor Cycles.

As a warning to prospective vendors of motor cycles, we would ask our readers especially to beware of the man who calls in reply to advertisements of motor cycles for sale, asks for a trial run and does not return. No trials should be given unless the money is deposited in notes with the owner of the machine. A case of this kind, recently reported in the daily papers, tells how Maurice McAdoo, age seventeen, was sentenced to six months imprisonment on a charge of stealing machines from a dealer at West Ham, and also six months for wearing a uniform and decorations to which he was not entitled; twelve months imprisonment in all. He sold five motor cycles worth £209 for £60, and appeared in court wearing the R.A.F. uniform and five ribbons, including the D.S.O. and D.S.C.

Special Features.

IMPRESSIONS OF THE PARIS SALON. ROAD TESTS OF NEW MODELS.

Police Activity.

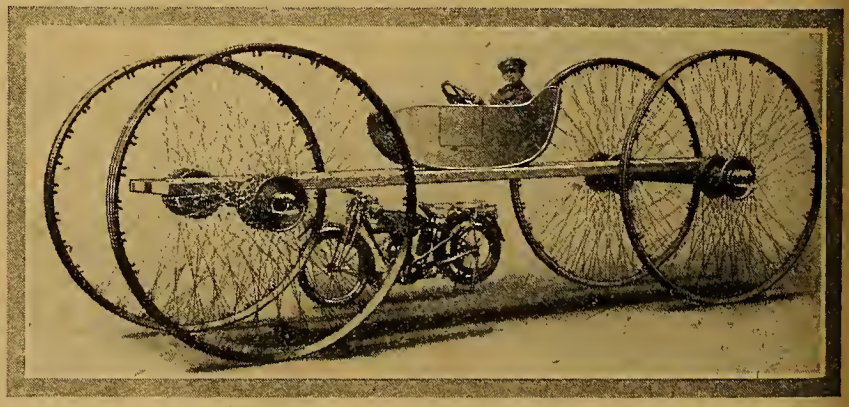
Motor cyclists are cautioned when riding in the neighbourhood of Brixton, as a police trap is in operation between Brixton Church and the George Canning.

Noisy Motor Cycles.

The majority of our readers doubtless know that "any noise annoys an oyster, but a noisy noise annoys an oyster most." If, without wishing to be too personal, we substitute "non-motoring public" for oyster, we arrive at the head and fount of the motor cycles offending. The subject was thoroughly discussed in the leading article in last week's issue.

Rear Lights and Accidents.

The National Council of the Commercial Motor Users' Association has had under consideration the regulations governing the lighting of road vehicles, with particular reference to their relation to accidents, and has informed the Ministry of Transport and the Home Office that it welcomes, in the interests of the public safety, the temporary reimposition of the provisions of Part 1 of the Lights (Vehicles) Order, and is of opinion that these provisions should be made permanent, at the same time urging upon the Government the wisdom of the reimposition of the Lights (Animals) Order. Road transport will be unsafe, alike to cyclist, pedestrian, animal drover, and vehicle driver, if any of the provisions of either Order should be allowed to lapse.



Wire wheels manufactured by Rudge-Whitworth, Ltd., for aerial ropeway conveyors. Their comparative size may be judged in contrast with the Rudge-Multi in the background. The "Heath-Robinson" vehicle, facetiously assembled for the photographer's benefit, will *not* be included in the 1920 Rudge programme!

Petrol and Profiteering.

The Board of Trade announces that the Profiteering Act, 1919, Maximum Prices Order No. 2, which fixed maximum prices for the sale of motor spirit, has been revoked. We wonder why!

A £40 Motor Cycle.

A new machine fitted with a 2¾ h.p. two-stroke engine, Brampton or Druid forks, E.I.C. magneto, Amac carburetter, and 24 × 2in. tyres will shortly be placed on the market by Mr. F. A. Wastell, of High Street, Orpington.

A Three-cylinder Radial-engined Car.

A remarkably light car design—the Cosmos—fitted with a three-cylinder Y type air-cooled radial engine and three-speed gear box, will be described and illustrated in this week's issue of *The Autocar*, dated 25th inst.

Cars at Olympia, November 7th to 15th.

The first of the Special Olympia Show Numbers of our parent journal, *The Autocar*, will be published to-morrow, Friday. The main contents are devoted to accessories. Next week the Buyers' Guide of 1920 model cars, with all leading chassis details, will appear, followed by the Olympia Show Forecast and Guide on November 8th, and the Report on November 15th. Motor cyclists (particularly those migrating to the light car), who desire to keep themselves *au fait* with developments in the automobile world, should order copies of *The Autocar* Special Olympia Show Numbers.

Motor Speeds at Hitchin.

The local police have informed the Royal Automobile Club that, owing to the excessive speeds at which motorists have been driving in Hitchin, they are instructed strictly to enforce the provisions of the Motor Car Act. The R.A.C. is accordingly co-operating with the Hertfordshire Constabulary to prevent illegal driving in and about the town, and the Club desires to issue a warning to all motorists residing in or passing through the locality. The Club has also informed the Chief Constable of Herts. that it is quite willing to provide R.A.C. "Please Drive Slowly" signs for erection at the principal entrances to the town.

A.C.U. Consulates.

There is every reason to believe that the consular service of the Auto-Cycle Union will soon be a very valuable feature of the facilities offered by the Union to members. Application for the post of local consul is invited from members.

An International Conference.

Mr. T. W. Loughborough, Secretary of the Auto-Cycle Union, is calling a conference of national bodies in his capacity as Secretary of the Fédération Internationale des Clubs Motocyclistes. The meeting will probably be held in London next December, when the curious situation which has arisen in America in connection with motor cycling competitions will be discussed. The representative American body associated with the F.I.C.M. is the Federation of American Motor Cyclists.

The Ford Type of Motor Cycle.

If present plans fructify, there will be more than one machine on the market next year designed to sell at a popular price. One of these is a large two-stroke intended for solo or sidecar work, which, it is expected, will be sold at the price of present-day lightweights.

An Autumn Trial in Wales.

Everything is being done by the secretary and officials of the Liverpool Motor Club to make the autumn trial a great success. This will be held next Saturday over a 115 mile course in Wales. The trial will start and finish at Birkenhead, and at about twenty miles from the start there will be an acceleration test, followed immediately by a brake test. These tests will take place between Northop and Holywell, and at Ruthin, where the first competitor is due at 12.15. There will be a one and a half hour lunch stop. The start will be from Hamilton Square, Birkenhead, at 9 a.m., and the finish at the Woodside Ferry Hotel at 4.58 p.m. An average of 18 m.p.h. is the schedule speed.

Benzol or Benzole?

At the Delegates' Meeting of the N.M.C.F.U., held in Lichfield on Saturday evening, Mr. S. Henshaw, of the National Benzole Association, was asked, among other questions, if he would explain the adoption of the spelling "benzole" by the Association, as opposed to the spelling "benzol" often used. He replied that the word "benzol" had a particularly German flavour, the spirit being so called in all their text books on manufacturing chemistry, whilst English chemists consistently adopted the spelling "benzole." When the N.B.A. was formed, the question of spelling was deliberated upon, and it was unanimously decided to use the latter form—in short to add the "e" and make it thoroughly British. Incidentally, we would point out that this spelling has always been used by *The Motor Cycle*.

A Reunion of D.R's.

With a view to arranging a reunion of D.R.'s of the 3rd Signal Squadron, R.E., we have been requested to ask all D.R.'s who served with this unit, or with the 6th, 7th, and 8th Signal Troops, to send their address to R. Channon, 6, High Street, Dorchester.

A Welcome Home.

We congratulate Mr. Humphreys, the chairman, Mr. R. H. Henderson, the secretary, and the committee on the great success which has attended their dinner, referred to on pace 460, and hope similar success will be attained with the suggested extension of the scheme.

French Kilometre Records.

The French official kilometre records, which were held in the suburbs of Paris during the Show, did not bring together many competitors. The trials had to be postponed twice on account of the weather, and when finally held, on October 15th, the conditions were only moderately good.

In accordance with the international rules, the kilometre had to be covered in both directions and the average time taken. Of the five motor cycles the fastest was Pean's 500 c.c. Peugeot, which established the record of 32 3-40s. for the flying kilometre. This is equivalent to 69.5 miles an hour. On his outward run Pean attained a speed of 74.5 miles an hour. The following are the results, the time given being the average for the out and home run:

SOLO (250 c.c.).—Alcyon, 60 1-40s.
SOLO (350 c.c.).—Alcyon, 35 11-40s.; Alcyon, 36s.
SOLO (500 c.c.).—Peugeot, 32 3-40s.
SIDECARS (1,000 c.c.). — Harley-Davidson, 47 18-40s.

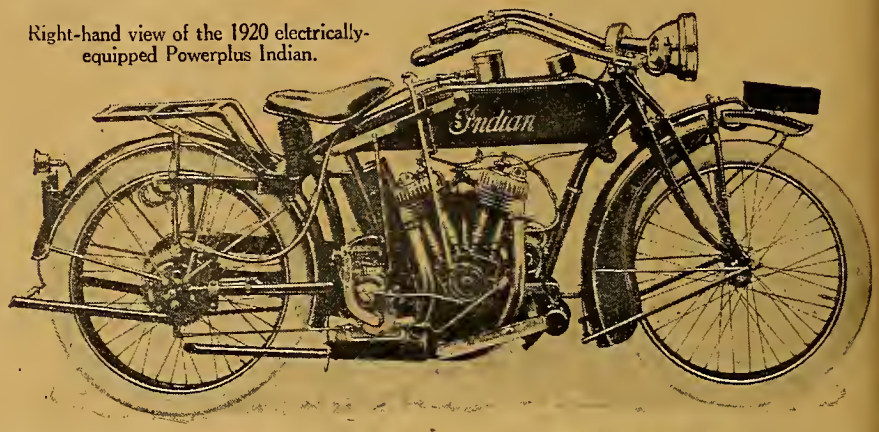
A flashlight photograph taken at the Grand Hotel, Birmingham, last Friday, when 200 local motor cyclists who had served in the war were entertained by those "who stayed at home."

THE 1920 INDIANS.

Two Models: 596 c.c. Scout and 997.6 Powerplus.

WE have received advance details of the Indian models which will be actually on view at Olympia, but the machines themselves have not yet arrived, though we had an opportunity of inspecting the Scout Model G20 at the Grand Palais, to which reference was made in the last issue. This is an attractive medium-weight mount, which should be ideal for solo work, but at the same time quite powerful enough for a sidecar. It is new in conception, new in design, and shows several novel constructional details; moreover, it is powerful, strong, and 100 lb. lighter than the Powerplus.

Right-hand view of the 1920 electrically-equipped Powerplus Indian.



Power Unit of the Scout.

The engine is of the same type as the Powerplus, but has a bore and stroke of 70×78 mm. (596 c.c.). The nominal rating is 5 h.p., though it actually develops 11 h.p. on the dynamometer. Roller bearings are fitted to the connecting rod and mainshaft. Large valves are used, so that a maximum efficiency is obtained, while the engine, with clutch and three-speed gear, forms a unit power plant.

Transmission to the gear box is by wide face spiral gears running in an oil bath. A steel disc clutch also running in oil is provided, which forms a smooth and positive engagement, and is worked by a rocker pedal on the near side footboard. The gears are actuated by a direct-acting change speed lever on the casing of the gear box, enabling an easy change to be made. The rear drive is by a ⅝in.×⅜in. chain, which is protected by means of a chain guard. The gear ratios are 5 to 1 high gear, 7.7 to 1 second gear, and 12.2 to 1 low gear. A kick starter is provided, acting on the mainshaft of the three-speed gear.

Carburetter and Ignition.

The carburetter is the Indian-Schebler, and though of the automatic variety it is capable of being altered to suit atmospheric conditions. We have had considerable experience with this type of carburetter, and find that it is capable of instantaneous acceleration without choking, while the slow running is all that can be desired. A Splitdorf Aero high-tension magneto, totally enclosed so that it is dust and waterproof, provides the ignition. Lubrication is by means of the well-known Indian system of mechanical oil pump, aided by an auxiliary hand pump.

The Cycle Parts

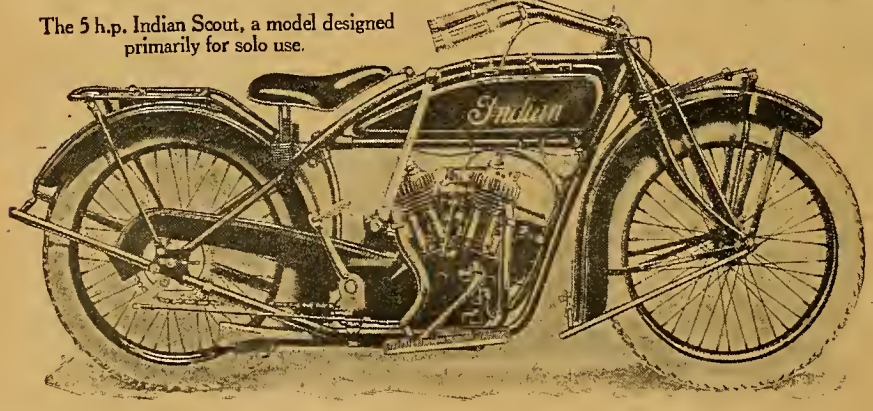
The frame is of the Indian double tube type, and is composed of special steel tubing and heavy drop forgings. The power unit is suspended at three points, and has a low centre of gravity, but yet ample clearance. At the same time, it is protected by the frame-member which passes below it.

Spring forks of the Indian triple stem type with double anchorage for the handle-bars are used. They are reinforced by truss rods, and the bushings for the movable parts are renewable in case of wear. Double brakes are provided, the internal brake being foot applied, while the external brake is actuated by lever on the handle-bars. Both brakes are independently adjustable.

The wheels are 26in. × 3in., and are provided with flat base rims. The wheel hubs, rims, and spokes are finished black, while withdrawable axles to the front and rear wheels are provided, allowing easy detachability. Front and rear stands are provided, and have "anti-rattle" mountings.

The petrol tank holds 2½ imperial gallons of fuel, and the oil compartment 2½ imperial quarts; there is a priming squirt in the petrol filler cap, and the lubricating pump is enclosed in the oil compartment.

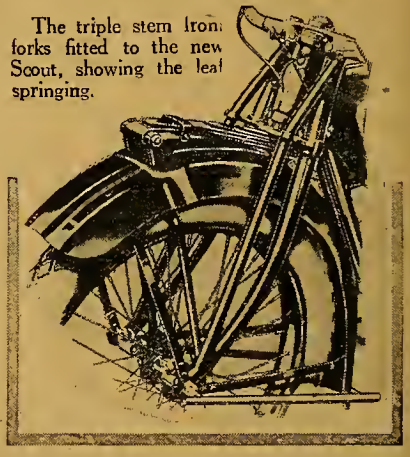
The 5 h.p. Indian Scout, a model designed primarily for solo use.



The Powerplus Model.

The Powerplus electrically equipped model has already attained a high degree of popularity in this country. Its engine has been improved by the fitting of larger inlet and exhaust valves; its bore and stroke are 79.3 mm. × 100.8 mm. respectively (997.6 c.c.). Roller bearings are fitted to the big end and mainshaft.

The triple stem Indian forks fitted to the new Scout, showing the leaf springing.



In the main the Powerplus model has not been altered to any very great extent. It is still supplied with the Splitdorf Aero high-tension magneto, giving a maximum spark intensity at all speeds. This is kept entirely separate from the Splitdorf direct current generator, which is driven by a spring wire belt directly from the engine. The petrol tank holds nearly three gallons of fuel, and is divided into two compartments, each with its separate filler cap and petrol tap. The oil tank holds 2½ quarts of lubricant.

The Transmission.

Transmission is by Renold chains amply protected by chain-guards, and the gear ratios are 4.75 to 1 high gear, 7.12 to 1 second gear, and 11.87 to 1 low gear.

The frame is the Indian cradle spring pattern, which has proved its excellence during the last seven years. It is composed of chrome Vanadium steel tubing and heavy drop forgings, while the head

The 1920 Indians.—

is webbed and of one piece, giving additional strength. The brakes are arranged in a manner similar to that adopted in the Scout model. The tyres are 28in. × 3in. on flat base rims, and the finish of the hubs, rims, and spokes is the same as on the previous model.

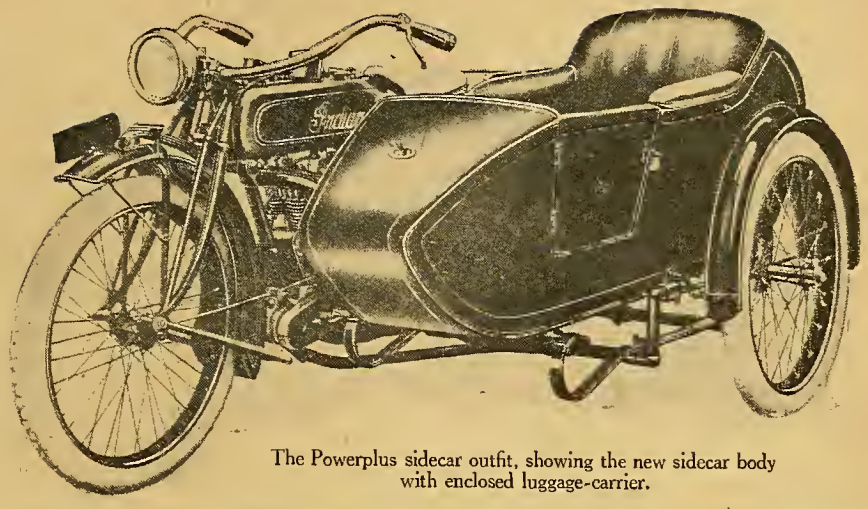
Enclosed Kick-starter.

The starting mechanism is on the right-hand side and enclosed, with the quadrant and pinion running in oil. As before, twist grip control is fitted. An improved design of bell crank levers on the forks gives greater strength and increased bearing surfaces.

Minor details are a larger carburetter, larger filler caps, and numerous other small innovations.

Reverting to the electrical equipment, there is an ammeter on the top tube which indicates at all times the amount of current going to the battery and shows the condition of the entire electrical installation.

So far as the sidecar is concerned, the body has been entirely redesigned for 1920. The seating accommodation for the passenger is most luxurious, and at the back of the sidecar there is a large receptacle, which is sufficiently roomy to take a considerable amount of luggage as well as extra petrol and oil.



The Powerplus sidecar outfit, showing the new sidecar body with enclosed luggage-carrier.

THE 1920 BAT MACHINES.

Renewed Energies of an Historic Firm. Two Powerful Passenger Machines.

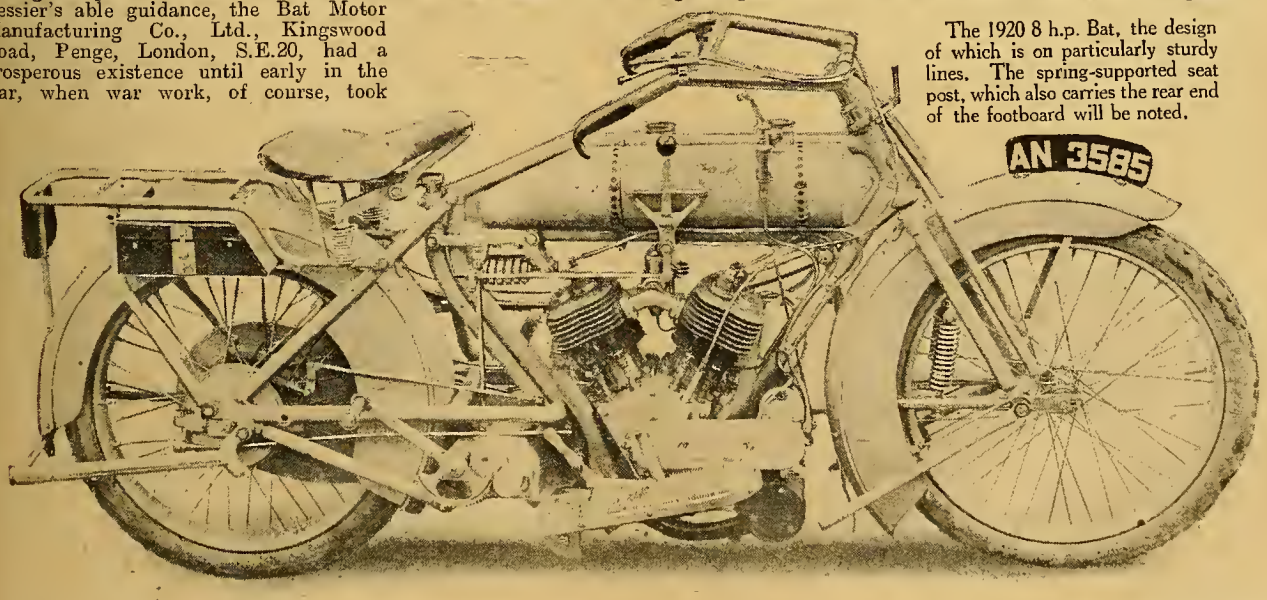
THE Bat motor cycle has been so long with us that any reference to these machines cannot fail to interest our readers. A brief history of the company is worth recording. The Bat first appeared in 1902, and, ridden by those famous experts, the brothers Chase, soon leapt into prominence by gaining a long series of records on the Crystal Palace track. Towards the end of 1904 the original firm died, but was revived by Mr. T. H. Tessier, who had ridden these machines with considerable success during the previous season. Under Mr. Tessier's able guidance, the Bat Motor Manufacturing Co., Ltd., Kingswood Road, Penge, London, S.E.20, had a prosperous existence until early in the war, when war work, of course, took preference over motor cycle manufacture, so that it was with great pleasure that we heard early this year that it had once more been revived, with the son of its old managing director, Mr. S. T. Tessier, as works manager.

6 and 8 h.p. Models.

Two practically identical models are now being manufactured—a 6 h.p. and an 8 h.p., with J.A.P. engines. The old and long tried system of springing is retained, which consists in isolating the seat-pillar and footboards from the rest of the frame, the shocks being absorbed by a coil spring in tension.

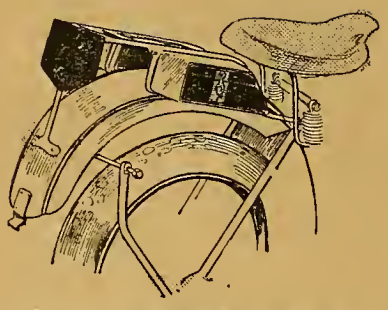
A feature of considerable interest lies in the method of holding the gear box, as, instead of being suspended from a bracket, it rests upon a platform, which is supported at its forward end close against the crank case and at its rear-most end by tubes running from the back fork ends below the chain stays. The gear box is held by means of bolts running through longitudinal holes, and the fact that it is not hanging by its own weight renders it quite easy to slide it back and to take up any slackness there may be in the chains.

It will be noticed that the kick starter has a partially enclosed pinion on the gearshaft, and that it is designed to give the leverage which is necessary when turning over a powerful engine. Another excellent feature of the gear box is that it is provided with a large inspection cover which can be removed without interfering with the adjustment of the striking mechanism.



The 1920 8 h.p. Bat, the design of which is on particularly sturdy lines. The spring-supported seat post, which also carries the rear end of the footboard will be noted.

The 1920 Bat Machines.—



The Bat rear mudguard, lifted up and resting on the bolt, previously withdrawn from the carrier stays, thus allowing access to the tyre.

In many respects the present model Bat closely resembles the pre-war pattern, but several details and refinements have been embodied with a view to its improvement.

The spring forks, however, which have been so long associated with this model are still retained, and it is interesting to note that the fork arms work on adjustable ball bearings, so that any play which might occur after prolonged use can be taken up at once.

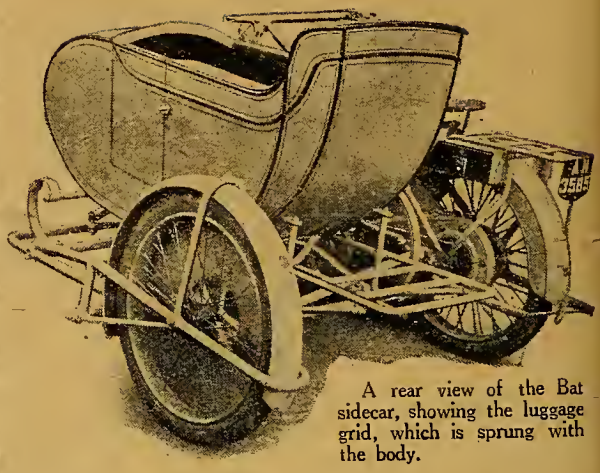
A Rear Wheel Clutch.

The rear mudguard is now capable of being lifted up so as to allow of easy access to the back tyre, and this is effected by withdrawing the long bolt beneath the luggage carrier just behind the large metal enclosed tool case.

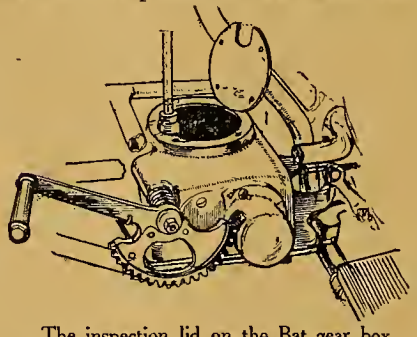
Contrary to the practice followed by most makers, the clutch is carried in the rear hub, and consists of an internal expanding phosphor bronze ring. There is one pedal on the near side, the first movement of which withdraws the clutch, any further movement applying the external band brake on the back hub. On the off side of the machine is another pedal, which actuates an internal expanding brake in the same drum as that to which the external brake is applied.

The transmission is entirely enclosed, and the chain cases are easily detachable. The mudguarding has been well designed, and both front and rear guards are deeply valanced.

In the case of the sidecar, the comfort of the passenger has been carefully studied; it is well-upholstered, and the wheel is sprung, the movable portion of the mechanism running on ball bearings. A substantial and spacious luggage carrier is attached to the sidecar body, so that the luggage is as well sprung as the passenger. The machines are finished in light grey, and have an exceedingly attractive appearance.



A rear view of the Bat sidecar, showing the luggage grid, which is sprung with the body.



The inspection lid on the Bat gear box may be removed without disturbing the striking mechanism.

The Bat on the Road.

We had a short run on the machine, which was driven by Mr. S. T. Tessier, and found that it pulled well and was exceedingly comfortable, not only from the passenger's point of view, but from the driver's as well.

From whatever point of view the Bat machines are regarded, it is obvious that the road experience of practical riders has dictated the main essentials of the design, which is characterised throughout by great strength and robustness.

THE 2½ h.p. P. & S.

A Fully-equipped Two-stroke Lightweight.

THIS is a motor bicycle of which we have had some considerable riding experience but under another name. The machine is now handled by Messrs. Pearson and Sopwith, 60, Mortimer Street, London, W.1, and is a handy, moderate-priced little mount, well equipped and highly suitable for those who prefer a lightweight two-stroke which is capable of going anywhere.

Since our last reference to the machine, it has undergone one or two improvements. The tank is of larger dimensions and now holds 1¼ gallons of petrol and a quart of oil, sufficient fuel being carried for 130 miles, which is a great improvement on the previous model, the tank capacity of which was distinctly limited.

The power unit is a 2½ h.p. Villiers, and the gear box is a Burman, provided with a kick-starter.

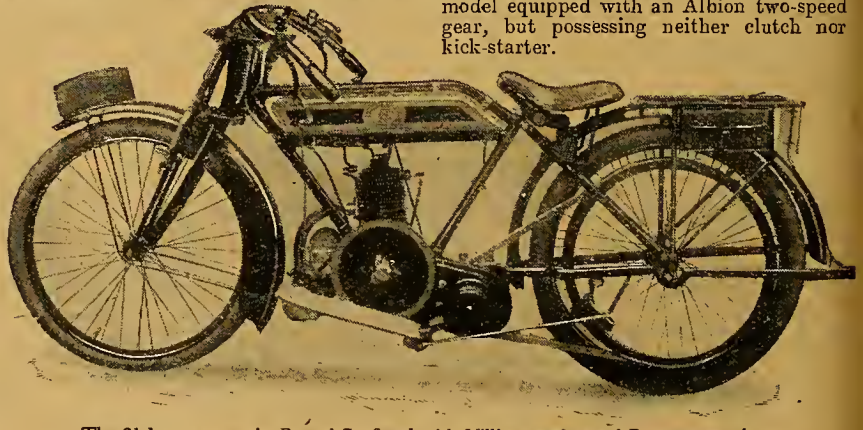
Formerly, the position of the brake pedal at the rear of the comfortable aluminium footboards caused the rider's heel to come in contact with one of the gear spindles when actuating the brake, causing considerable damage to the boot. This has been overcome by placing the pedal in a more convenient position forward of the footboard, so that it is actuated by the ball of the foot, and the gearshaft having been shortened is no longer in the way. In actual practice, we found the two-speed gear, clutch, and kick-starter to work admirably.

A further improvement lies in the introduction of a chain guard and of a valance to the rear mudguard.

Reverting to the speed gear, the clutch is actuated by a lever on the handlebars, and very little effort is required to effect its withdrawal.

The machine is well-equipped, has a comfortable Lycett pan saddle, Best and Lloyd drip-feed lubricator, C.A.V. magneto, and either a Brown and Barlow or Amac carburetter. Two-inch tyres on 26in. wheels are supplied.

There is also a simpler and cheaper model equipped with an Albion two-speed gear, but possessing neither clutch nor kick-starter.



The 2½ h.p. two-stroke P. and S., fitted with Villiers engine and Burman gear box.

The N.M.C.F.U. Delegates' Meeting at Lichfield.

ON Saturday, delegates from many branches of the National Motor Cyclists' Fuel Union assembled at the George Hotel, Lichfield, to be present at the executive and delegates' meeting, which took place at 6 p.m. Thanks to the splendid weather conditions prevailing, the majority journeyed there by road, and spent the afternoon inspecting the antiquities of the old town. A large party from the Coventry and Birmingham branches met at Stonebridge, and joined forces on the run to Lichfield, while amongst others noticed at the meeting were representatives from Derby, Sheffield, Liverpool, Portsmouth, London, and Barrow.

The chair was taken by Mr. E. S. Shrapnell-Smith (president), while Mr. A. W. Torkington (National chairman), Mr. W. Ellis (secretary), and Mr. T. W. Loughborough (the secretary of the A.C.U.) were also present.

As questions largely relating to the selling prices, quality, and distribution of benzole occupied a prominent position on the agenda, Mr. S. Henshaw (vice-chairman of the National Benzole Association) was invited to attend, and during the course of the meeting gave some interesting information.

Dealing first with the benzole question, resolutions were read strongly condemning the variations in price and overcharges common in many districts, and specific instances were given.

Mr. Henshaw, replying, said that benzole manufacturers who were members of the N.B.A. (and this included the majority) had made no recent advance in price. They agreed to sell to the dealers in bulk at 2s. 3d. per gallon, or in tins at 2s. 4d. per gallon, and that dealers were authorised to sell at a profit of 5d. per gallon; therefore any retailer charging more than 2s. 9d. per gallon was clearly profiteering, and the N.B.A. was most anxious to have such cases brought to its notice.

Speaking of the present price of benzole as compared with the charge of 1s. 3d. per gallon (retail) common in 1913 and 1914, he mentioned that coal, which then cost 9s. per ton at the distillery, now cost 28s., while coke-oven men, who before the war received 5s. daily, now had a wage of 14s. per day, plus a small bonus. All other costs were similarly increased; therefore, rather than the present price of 2s. 9d. per gallon being a matter for complaint, he considered that the manufacturers were to be congratulated on keeping it at this figure. The output of benzole in this country he stated to be over twenty million gallons annually, and still increasing; therefore it merely required improved distribution to supply all the needs of motorists in this country. Distribution was improving, and, given the co-operation of private motorists, it would soon be possible to establish its general use.

A resolution, proposed by the Leicester branch, was next made strongly opposing the abolition of the Order necessitating rear lights on cycles, cattle, and slow-moving vehicles, and in the discussion which followed, Mr. F. Murray (Birmingham), speaking both as a member of the N.M.C.F.U. and of the Clarion Cyclists' Club, suggested that the rear light Order should be maintained, but that, in the case of cycles, a properly designed reflex "light" should be considered as complying with the law. The carrying of rear lights was not objected to by the majority of cyclists, provided they were protected from the petty persecution of the authorities on account of the rear lights being extinguished by jolting over bad roads.

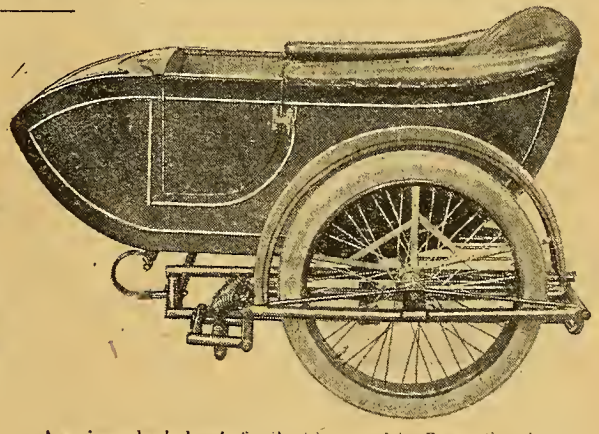
A further amendment was added that solo motor cycles shall be regarded as "cycles."

The next matter of general interest dealt with the proposals which are likely to be made by the Chancellor of the Exchequer regarding an all-round revision of motor taxation, and Mr. Shrapnell-Smith remarked that it was felt, in comparison, for example, with a heavy hire car paying a 15s. hackney carriage licence, that the motor cycle was disproportionately taxed.

The resolution to be put forward was that taxation should be upon the wheel basis, and that motor cycles should pay 2s. 6d. per wheel per annum. This suggestion met the views of all present and will form part of the propaganda programme of the N.M.C.F.U. when these proposals are brought up at the next annual general meeting, which will be held on December 6th at the Imperial Hotel, Birmingham, at 6 p.m.

The Use of Welding in Sidecar Construction.

The Bamco Chassis from which Brazed Joints are Eliminated. A Novel Type of Wheel Springing is Incorporated.

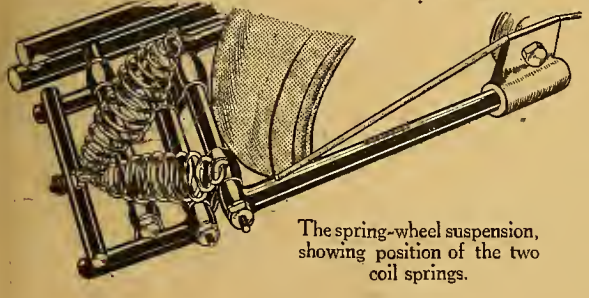


A spring-wheel chassis fitted with a special "Bamco" body

MUCH experience has been gained during the last few years in the employment of the oxy-acetylene welding process in conjunction with aircraft construction, and it has revealed its manifold advantages with regard to ease of manufacture and durability.

Based on this experience, the Birch Manufacturing Co., Willesden Green, N.W., have applied the process to a chassis which they propose to place on the market at no distant date.

A popular model, incorporating a new spring wheel design, is shown in the illustration. The sidecar wheel is held by means of a "knockout" bolt through the hub at the centre of the two longitudinal tubes, which, with the rear cross member on which they are pivoted and the front cross member, form a cradle sprung with the wheel. This cradle is attached at the forward end by two links to a rectangular member free to rock on an extension of the chassis, and two coil springs control its movement. The action of this suspension is very simple, and is made quite clear by the sketch.



The spring-wheel suspension, showing position of the two coil springs.

The springing of the sidecar body is, although of standard pattern, interesting, as the two coil springs on which the rear of the body is held are suitably enclosed, thus excluding dust and mud and presenting a smart appearance. The coil springs are provided with a bolt which passes through a slot in the spring container, and is then attached by means of a clip to the rear cross-member, to which the body is bolted. The front springs are of the conventional C spring type. Substantial three-point mudguard attachments are fitted to all sidecar chassis, thereby decreasing the one possibility of a breakage, the welded chassis having proved its strength during the extensive and searching trials recently carried out.

Although not at present available, we understand that other spring wheel designs will appear shortly. Three other models will also be produced by the designer, Mr. H. E. Monti; all of these, however, are rigid. The medium-weight and standard models have 26in. wheels.

C9

The Midlands Honour Service Motor Cyclists.

A Successful Welcome Home.

BIRMINGHAM probably has more motor cyclists per thousand of its population than any other city in the world. Add to this the large numbers of riders in the immediate surrounding districts, and one is not then surprised that the Midlands were well represented by these motor cyclists in every branch of the services fighting in the great war.

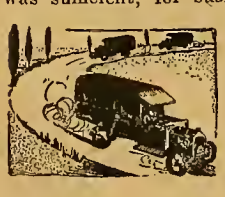
Last Friday evening, two hundred of those who had returned were entertained at the Grand Hotel, Birmingham, by a committee representative of the sport, pastime, and trade in the Midlands.

Immediately on arrival at the rendezvous, it was clear to us that this was more than a reunion of local motor cyclists, although, even as such, it was undoubtedly a great success. What impressed us more was the significance of such a meeting—a further proof that motor cyclists form a fraternity such as does not exist among participants in any other pastime—and proof, too that the brotherhood's part in the war has not been, and will not be, forgotten by those who "stayed at home." The committee's scheme is not finished with a dinner and entertainment, and endeavour is to be made to ensure that those who helped to win the war, and incidentally to place the motor cycle above the category of a sporting machine in the eyes of the public, will not suffer through difficulties in re-establishing themselves in their proper place in civil life. Such was the spirit behind "the welcome home to Birmingham's service motor cyclists," at which Col. Sir William Bowater presided last Friday.

Reunions.

Although there were a large number of clubmen present, we think the majority were "unattached riders."

Among these we noticed several cases of the meeting of men who were comrades in the various fields of war, which shows that in large cities there may be hundreds of old comrades who are out of touch with their fellows, and that a reunion of this nature must be a great source of pleasure to men who have battles to fight again. Representatives of all grades of the motor cycling public were present—but all were motor cyclists, and that was sufficient, for such is the fraternity of motor cyclists that class and distinction of any kind are not recognised. The man who, before the war, saved enough to buy and run a second-hand machine of ancient make and the owner of perhaps a stud of machines *de luxe* had common interests; motor cycles before the war, motor cycles during the war, motor cycles of the present and the future.



The cover of the menu designed by S. Kempson Jones—one of the committee and also a guest.

A 6in. plaque was presented to each guest—a handsome souvenir inscribed "A symbol of the courage and sacrifices displayed by Birmingham and District motor cyclists who served in H.M. Forces."

Many of the guests bore scars of battle, some were maimed, a few disfigured. When the company rose to drink a silent toast to those who had fallen, one was reminded that the sport of motor cycling had lost many enthusiasts who had helped to make the modern motor cycle the efficient war machine it proved itself to be.

The President's Address.

The president of the movement, Col. Sir William Bowater, gave a very suitable address of welcome and referred to the difficult tasks of motor cyclists in the war, and paid tribute to the patriotism of Birmingham motor cyclists in particular. Mr. Frank Gazard, D.S.M. (the Navy), Maj. Wilson (the Army), Capt. Joseph, R.A.F., D.F.C. and bar (Air Force), and Mr. Howard R. Lane (despatch riders) responded.

Other speakers were Mr. Chas. Hyde (B.S.A. Co.), Mr. A. W. Torkington (president A.C.U.), Mr. Ernest Humphries (chairman of the committee) and Mr. R. W. Henderson (secretary).

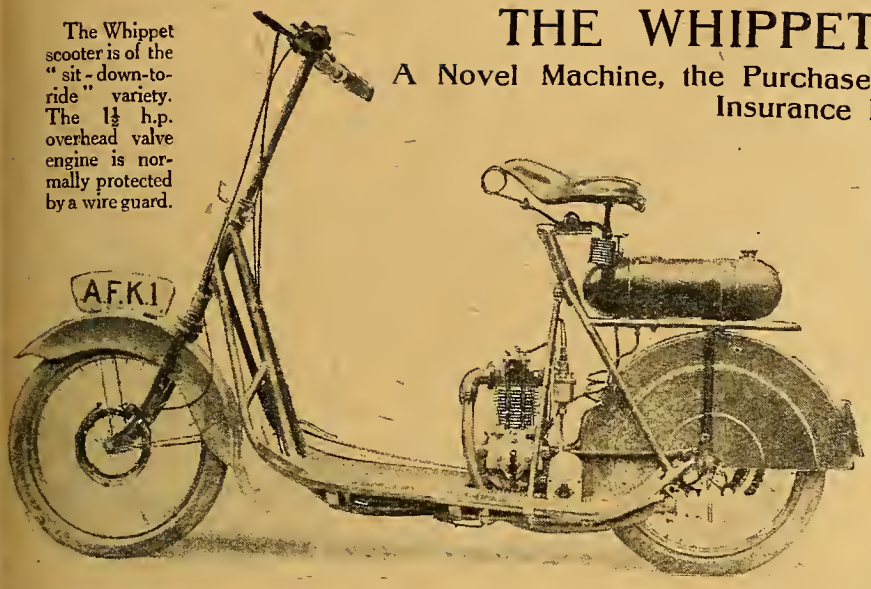
During the evening each guest was presented with a handsome copper plaque suitably inscribed—a photograph of which is reproduced on this page. A capital musical programme concluded a most brilliant evening.

A Good Scheme.

We should like to see similar gatherings in other motor cycling centres. Undoubtedly it means a great deal of labour and tenacity successfully to obtain the funds to carry such schemes into effect; in which connection it is interesting to know that the Birmingham function was brought about by a citizen committee through the instigation of Mr. Ernest Humphries of the O.K. firm. It is perhaps rather surprising that the stronger Birmingham clubs did not take a more prominent part in the work; in fact, we heard more than one criticism of the clubs in this connection, one very energetic clubman venturing to remark that the only official acknowledgment of a member's return to civil life being a civil demand for his subscription. The donations that were collected by the committee amounted approximately to a total of £400.

THE WHIPPET SCOOTER.

A Novel Machine, the Purchase of which includes a Free Insurance Policy.

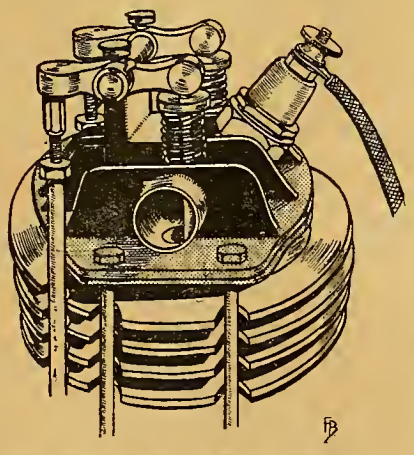


The Whippet scooter is of the "sit-down-to-ride" variety. The 1½ h.p. overhead valve engine is normally protected by a wire guard.

MANY have been the designs of motor scooters since the first idea of elaborating a foot-propelled machine set the ball rolling. A considerable amount of controversy has also arisen with regard to the most suitable position for the power unit, and some designs have suffered through the weights and stresses being unsuitably distributed. A sound method of construction, however, has been adopted by W. G. C. Hayward and Co., Ltd., Beaufort Works, Cambridge Park, Twickenham, who have based the design of the Whippet scooter on motor cycle principles.

Features of Design.

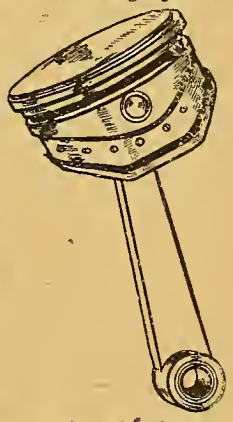
The foremost of the many features incorporated in the design is the 1½ h.p. four-stroke engine, which is mounted in front of the rear wheel, and protected by a collapsible wire cowl. An aluminium cylinder, machined all over, is shrunk on to a steel liner, and mechanically operated overhead valves are housed in the cast iron detachable combustion head, which is securely held in position by four long bolts. A patented exhaust lift or half compression device is incorporated, which consists of a shaft sliding within the cam wheel bush, and provided with a small cam which can be removed beneath the exhaust valve rocker. A steel crankshaft of orthodox pattern is employed. An unusually long phosphor bronze bush, however, is used on the external flywheel side of the crank case, and an aluminium piston, having two cast iron rings, is fitted. Lubrication by splash feed has been found satisfactory, the oil being fed by a hand pump from the tank, which has a capacity for 250 miles. The large portion of the tank holds 1¼ gallon of petrol, which passes through a filter to the standard pattern Amac carburetter. All-chain transmission conveys the drive to the rear wheel, the countershaft being situated in rear of the tubular saddle member. The position of the magneto is somewhat unusual, it being mounted practically out of sight, on the near side of the countershaft, from which it is driven. The large chain sprocket on the off side of the countershaft incorporates a shock absorbing device, and the gear ratio at present employed gives a reduction of 9½ to 1.



Cylinder head and overhead valves of the Whippet 1½ h.p. engine.

Internal Expanding Brakes.

The chassis is constructed of twin steel tubes throughout, and domed front and rear mudguards are provided. Internal expanding brakes are employed, that fitted to the front wheel being operated by a Bowden lever on the wide handlebars, whilst the rear is foot-operated. The silencer, which is of special construction, consists, broadly, of a restricted venturi tube, with cooling rings cast about its circumference.



The piston and connecting-rod. The former is of aluminium with two cast iron rings, and has a recessed oil trap. Its unconventional shape is due to its being cut away to clear the crankshaft bob-weights

During the searching tests to which it has been subjected, the Whippet is said to have exceeded 25 m.p.h., and has carried three persons up a gradient of approximately 1 in 6. The price of forty-seven guineas includes a free insurance policy for the period of one year.

PRICES IN 1920.

AT the present time there are many rumours concerning the price of 1920 machines. In some quarters opinion is freely expressed that few full-powered sidecar outfits will be less than £200 next year, while in other directions there are signs that prices may be lowered. One cannot imagine, however, that prices of the present type of vehicle are likely to undergo any considerable modification on account of the high cost of raw material and labour. On the other hand, it is quite on the cards that we shall see passenger machines which differ radically from our present ideas and from conventional practice.

The question arises, however, as to whether the motor cycle public, which, to say the least, is a most conservative body, will be prepared to subordinate its preconceived ideas to the notions of the more advanced school of designers. We would remind our readers that it is quite possible to produce a perfectly satisfactory article at a price suited to the pocket of the average motor cyclist, provided that exception is not taken to somewhat unconventional appearance.

IMPORTANT DATES.

Athens Motor Show	Oct. 13th to Nov. 14th.
Olympia Car Show	Nov. 7th to 15th.
Olympia Motor Cycle Show,	Nov. 24th to 29th.
Brussels Show	Dec. 8th to 13th.
Paris Aero Exhibition	Dec. 19th to Jan. 4th.
New York Show	Jan. 3rd to Jan. 10th.
Paris-Nice Trial	Feb. 13th to 16th.
Birmingham British Industries Fair	Feb. 23rd to March 6th.

The Four-cylinder Henderson on the Road.

Some Experiences with an Increasingly Popular Type of Power Unit.

The 10 h.p. four-cylinder Henderson, the engine of which is 69.85 × 76.2 mm. = 1,168 c.c.—an example of a type which is being considered by British manufacturers.

FOR many years we have realised the possible future of the four-cylinder motor bicycle, and have made a special study of the type, having had road trials of each model of the Henderson ever since its first appearance in this country. We have exceedingly pleasant recollections of the earlier models, but the new one, which was described in our issue of July 17th last, is certainly a distinct improvement on its predecessors. Only those who have driven a four-cylinder motor bicycle can appreciate its charm when compared with existing single or twin-cylinder models, for the sensation of driving is exactly like that obtained in the handling of a powerful four-cylinder car. The machine has a wonderful acceleration, is an excellent hill-climber, and is beautifully controllable in traffic. Both clutch and change-speed gear perform their various functions in an irreproachable manner, the saddle is most comfortable, and the spring forks are excellent.

Our experience with the 1919 model, in contrast with those of previous years, was with a sidecar. As a solo machine it is ideal, despite its somewhat heavy weight, although in this respect it compares very favourably with most of the American twin-cylinder machines.

Its Performance in the Team Trials.

While the machine was in our hands, it was put to a pretty strenuous test. Being brand new, it was first of all driven fairly easily in gently undulating country, but, before it left our hands, it had to negotiate the stiff course selected for the M.C.C. Team Trial for *The Motor Cycle* Cup. It will be remembered in that trial that there were numerous stiff hills with rough surface, and every one of these was negotiated faultlessly.

The only point which we criticise is the somewhat unnecessary inaccessibility of certain parts; for instance, to detach the rear band brake, which we had to do in order to replace the lining material, the whole wheel had to be taken out, and we sincerely hope that in future models the design will be simplified so that such extensive dismantling will not be necessary.

As we have said before, the running of the machine was beyond all praise, while its speed on the level was all that could be desired. We have had for many years a strong belief in a successful future for the four-cylinder, and it is after riding a machine such as the Henderson, which was placed at our disposal by Mr. J. Robertson-Brown, of Messrs. Robertsons Motors, Ltd., 157b, Great Portland Street, London, W.1, that we feel that our dreams are at last being realised.

Novel Application of a Well-tried Chain.

WE recently spent a very interesting afternoon at the works of the Coventry Chain Co., and there inspected the many processes through which a motor cycle chain passes as the raw material is converted into the complete chain ready for use. Much of the automatic machinery seemed to be endowed with almost human intelligence in the way it handled the parts entrusted to it, and more than human diligence in the way it stuck to its work so long as the necessary material was supplied. The automatic feeding arrangements were, too, most ingenious and very fascinating to watch, as the small parts were thrown into position from the supply reservoir and thrown back again if they did not take their place correctly for the succeeding process.

The Coventry Chain Co. is particularly noted for that type of chain which is designed to take up a different position on its sprocket teeth as wear (generally called stretch) occurs, and known as the "Inverted tooth" chain. (Incidentally, a chain of this type, illustrated on page 275 in our issue for September 11th, is a Coventry noiseless chain, fitted to a Rover motor cycle.)

While we were at the works Mr. Watts showed us a chain which is new in its application to motor cycles and cycle cars, but not new in itself, for it is but a small edition of the chain used to drive the "Tanks," and supplied by the Coventry Chain Co. It is, in fact, a double roller chain, and it has an advantage in strength, weight, neatness, and smoothness of running over the larger chains designed for the same purpose, but to set against this is the small disadvantage that the sprockets are slightly more costly, as one extra process is required in their manufacture, and the chain itself contains more parts. This chain being rather wide suits cycle cars better than motor cycles.

Club News

Rochester, Chatham, and District M.C.

A prize distribution, whist drive, and dance is being held at the end of November. Those members who require tickets for themselves and friends should inform the hon. sec. The date has not yet been fixed. Hon. sec., Mr. S. White, 3, South Avenue, Rochester.

Southend-on-Sea and District A.C.

The recent gymkhana proved a great success and included events for motor cyclists and car owners. These were of a novel character, such as changing a sparking plug between starting and finishing lines, a "Blondin" race, in which solo motor cyclists had to keep on a track consisting of boards 9in. wide, musical chairs, and a slow race.

Ulster Hill-climb.

The Ulster Centre of the Motor Cycle Union of Ireland concluded its competitive season with a hill-climb near Carrickfergus. The sidecar class did not secure the necessary number of entries, but the two solo classes were well supported. Result: Novices.—W. W. Johnston (3½ Norton), 1; W. T. White (3½ Norton), 2. Open—E. Thompson (3½ Rudge), 1; J. B. Johnston (3½ Norton), 2; W. W. Johnston (3½ Norton), 3.

Hill-climb at Cork.

A hill-climb was held recently by the Cork and District Motor Cycle Club, the results being determined on formula. The times and placings in the various classes were as under:

CLASS I.—SOLO MACHINES UNDER 300 C.C.

1. J. Mulligan (2¾ Triumph) ..... 55⅘s.
2. R. Cogan (Wolf) ..... 67⅘s.

CLASS II.—SOLO MACHINES, 300-350 C.C.

1. R. S. Russell (2¾ Sunbeam) ..... 43⅘s.
2. F. Harrington (2¾ Coulson-B.) ..... 46⅘s.
3. O'Donovan (2¾ A.J.S.) ..... 50⅘s.
4. H. Burns (2¾ A.J.S.) ..... 48s.

CLASS III.—SOLO MACHINES, 350-600 C.C.

1. C. S. Hosford (4 A.J.S.) ..... 38⅘s.
2. J. Gibbings (4 Triumph) ..... 37⅘s.
2. R. T. Popham (3½ Norton) ..... 37⅘s.
4. J. A. Wilson (3½ Ariel) ..... 39s.
5. J. Mendelson (3½ Sunbeam) ..... 40⅘s.

CLASS IV.—SOLO MACHINES OVER 600 C.C.

Walk over. C. M. Ryan (8 New Imperial) .... 35⅘s.

CLASS V.—SIDECAR MACHINES UNDER 600 C.C.

1. Mahony (3½ B.S.A.) ..... 55s.
2. W. Williams (3½ Triumph) ..... 64⅘s.

CLASS VI.—SIDECAR MACHINES OVER 600 C.C.

1. Duggan (6 Enfield) ..... 50⅘s.
2. J. Ryan (7 Indian sc.) ..... 51⅘s.

In the Pike cup a handicap confined to those who did best on formula in their respective classes, the result was as follows:

	Time.	Handicap.	Handicap Time.
1. C. S. Hosford (A.J.S.) ..	37⅘s. ..	⅘s. ..	37s.
2. R. J. Popham (Norton) .	38⅘s. ..	Scr. ..	38⅘s.
2. J. A. Wilson (Ariel)	40s. ..	1⅘s. ..	38⅘s.
4. J. Mendelson (Sunbeam).	43⅘s. ..	3s. ..	40⅘s.

Future Events.

Oct. 23.—N.M.C.F.U., Leeds. Smoking Concert, "Green Dragon."
OCT. 25.—LIVERPOOL M.C. OPEN TRIAL FOR RELIANCE CUP.
Oct. 25.—N.M.C.F.U., Sheffield. First Winter Social.
Oct. 25.—South Birmingham M.C.C. Trial for Sangster Cup.
Oct. 25.—Finsbury Park C. and M.C. Tea and Lantern Exhibition, "The Mitre," Barnet.
Oct. 26.—Rochester, Chatham, and District M.C. Run to Bodiam.
Oct. 26.—Ilkeston and District M.C.C. Run to Chatsworth.
Oct. 31.—Meeting of Birmingham Club Officials to discuss Question of Amalgamation, Chamber of Commerce, Birmingham.
NOV. 1.—SOUTH BIRMINGHAM M.C.C. OPEN TRIAL FOR PALMER CUP.
Nov. 8.—Birmingham M.C.C. Closing Run.
Nov. 13.—N.M.C.F.U., Leeds. Annual General Meeting.
Nov. 21.—N.M.C.F.U., Leeds. Whist Drive and Dance.
Nov. 29.—N.M.C.F.U., Coventry. Run to Olympia Show.

Finsbury Park C. and M.C.

A tea, followed by a lantern exhibition, has been arranged for Saturday next, at the Mitre, Barnet. Hon. secretary: Mr. J. Evans, 33, Springdale Road, Stoke Newington, N.16.

South Birmingham M.C.C.

The Birmingham Motor Cycle Club reliability trial for the Sangster Cup will be held on November 8th; entries close on November 5th. The trial is organised as a sporting run, and a circular route of about one hundred miles has been chosen which introduces new ground to Midland competition riders. Full particulars may be obtained from Mr. T. Silver, trials hon. secretary, Frederick Road, Stechford, Birmingham.

West Lothian M.C.

A new club with a membership of fifty has been formed in Bathgate, Linlithgowshire. The hon. secretary is Mr. J. S. Cox, 93, South Bridge Street, Bathgate.

Liverpool Reliance Cup Trial.

The Liverpool Motor Club has a very sporting course in North Wales laid out for next Saturday's Reliance cup reliability trial. The trial promises to be a successful event, as more than forty entries have been received.

Kidderminster M.C.C.

There were forty-five entrants in the various events of the Kidderminster M.C.C. hill-climb held recently near Cleobury Mortimer. The gradient of the hill was 1 in 8 for 200 yards, the remainder averaging 1 in 20. Results:

CLASS 1.—350 C.C.

		Time.
1.	Pritchard (2½ Viper-Jap)	1m. 1s.
2.	Griffiths (2¾ Douglas)	1m. 1⅘s.
3.	Hayes (2½ Wolf-Jap)	1m. 22⅘s.

CLASS 2.—500 C.C.

†	Moule (3½ Rudge Multi)	48⅘s.
†	Fletcher (3½ Norton)	48⅘s.
3.	Pritchard (2½ Viper-Jap)	57⅘s.

† Dead heat.

CLASS 3.—600 C.C.

1.	Moule (3½ Rudge Multi)	47s.
2.	Hill (3½ Norton)	50⅘s.
3.	Radcliffe (4 Triumph)	51⅘s.

CLASS 4.—750 C.C.

1.	Moule (3½ Rudge Multi)	46⅘s.
2.	Radcliffe (4 Triumph)	47⅘s.
3.	Fletcher (3½ Norton)	49s.

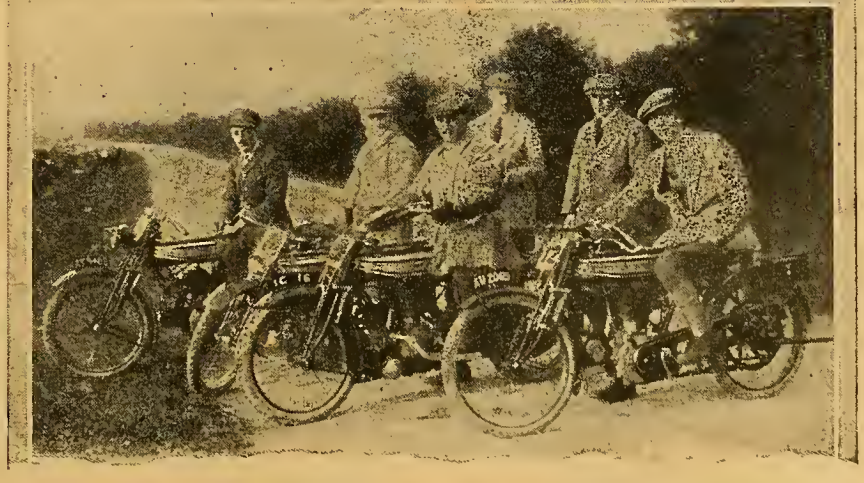
UNLIMITED CLASS.

1.	*Fellows (6 James)	42⅘s.
2.	Lowe (10 Henderson)	45⅘s.
3.	Moule (3½ Rudge Multi)	46s.

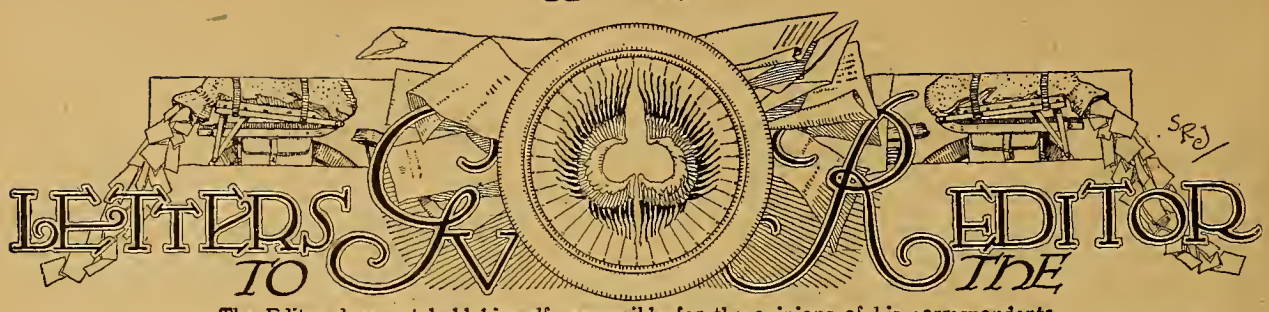
* Fastest time of the day.

CLASS 6.—SIDECARS ON FORMULA.

1.	Rhodes (4½ B.S.A.)	1m. 6s.
2.	Ivens (10 Henderson)	1m. 7⅘s.
3.	Lowe (10 Henderson)	1m. 15s.



A group of Norton owners at the recent speed trials held by the Nottingham and District M.C.C.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters must be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accomoanied by the writer's name and address.

DISSOLVED ACETYLENE.

Sir,—Will Mr. J. W. Pepper, who writes to the editor in last week's issue of *The Motor Cycle* as to the advantages of dissolved acetylene, kindly state where the D.A. cylinder he speaks of can be obtained? I have been on the look out for it for months, but have not found anyone who stocks or makes it. R. SMART.

MOTOR CYCLING IN ASSAM.

Sir,—In reply to E. T. Lycett-Burd, who writes in *The Motor Cycle* for October 16th enquiring about motor cycling in Assam, I may be able to give him a few hints, as I have lived in India fifteen years, and have had all sorts of motors whilst there.

(1.) *Re* A.B.C. and sidecar, I cannot give any opinion on this particular make, as I have yet to see one, but from accounts it should be quite satisfactory.

(2.) See above; the Triumph is excellent, but I am now riding a Sunbeam.

(3.) In this country.

(4.) Yes, English registration is *not* recognised out there.

I may add that your correspondent must not lose sight of the fact that, with the exception of the road from Gauhati to Shillong and Cherrapoongee, there is hardly a single road in Assam *worth the name*. Also, in the rains, he will not be able to do much, as the roads, being "kutcha," *i.e.*, only made of soft material, not stone, soon become quagmires.

I have had plenty of motoring experience in India, but if Mr. Burd has the means, the best he could do would be to buy a Ford car *there*, which he can do at less than he can get one here and take it out. I am a very keen motor cyclist, but for Assam roads the Ford is the best proposition I know. Petrol is cheap there, being obtained from the Assam Oil Co. at Digboi. G. F. L. ALEXANDER.

SPEED WOBBLE.

Sir,—With regard to the interesting discussion on "Speed Wobble," which I have followed in your paper, I do not claim to have any experience of this phenomenon, although I find a 6 h.p. combination very useful. The reason, no doubt, for my lack of experience may be found in the facts that (1) I am a poor man (which I know), and (2) I am a poor bargainer (which I shrewdly suspect), so that I have never whacked a machine up to 65 m.p.h. on the road, never having found the requisite machine under me.

I have a theory, however, that the "wobble" may be due to two causes:

(1.) The camber of the road.

(2.) The gyroscopic action of the engine flywheel and heavy moving parts at high engine speeds which, when combined with high bicycle speed and, possibly, therefore, with cause (1) above, may produce "wobble" as follows: The axis of the gyroscope is, in this case, at right angles to the line of advance or fore and aft line of the machine.

The rider, having "whacked up" to the requisite 65 m.p.h., sees some roughish looking stuff a little ahead of him, and swerves to avoid it. In doing so, he leans over (you *must* lean at 65 m.p.h.); this tilts the axis of the gyro, which causes it to "precess" (as the term is known), *i.e.*, turn in its vertical plane, or, in plain language, it endeavours to alter the direction of progression of the bicycle—but which way, you say? Now for the heavy guns of all our scientific friends, I say (without a reference book) it tends to alter the direction of the bicycle in the *same direction* as the swerve; it tends to increase the swerve; the rider corrects this, and leans the other way—more swerve. But, even if its enormous force tends the other way, the effect will undoubtedly be disturbing.

We now come to the point as to why slowing down does not correct this "wobble," and I can only submit the theory that the various movements of the rider get more agitated as he finds that his efforts are meeting with no success, and that, although the gyro speed is reduced, the rider's movements out of the vertical plane get more sudden, as I am concluding that the whole thing from "Speed Wobble Symptoms" to "Nirvana," or acquaintance with the "Macadam Clan," is a pretty short interval. The causes (1) and (2) are possibly combined with cause (3), *i.e.*, failure to sit and grip tightly, as the experienced riders seem to recommend.

It is hardly necessary, perhaps, to remind those who try to solve the "wobble" problem of the enormous force exerted by gyroscopic action. I venture to state that the problems connected with, say, the gyroscopic action of a big car flywheel as opposed to that of a motor bicycle flywheel whose axes are 90° different in plane may possibly prove interesting.

It will at once be objected that machines on first gear with engines racing ought to "wobble." I can only answer that they probably do and it does not matter, or that the rider does not lean over so much, hence less gyro action.

Dalton-in-Furness. THEORY.

Sir,—With regard to the cause of "speed wobble," may this not be due to unbalanced road wheels? Few people realise the enormous effect which an unbalanced tyre valve can have, especially at high speeds. The unbalanced weight of the double thickness of the inner tubes where it is joined also has an appreciable effect on the wheel. In fact, when timing a motor cycle for speed work this question of balance is much more important than any question of fancy valve or magneto timing. If the steering wheel were mathematically true in the vertical longitudinal plane in which the machine is moving, the lack of balance would not affect the steering until it had once been moved out of the longitudinal plane or the straight ahead position. But once the handlebars had been moved the slightest fraction vibration would be set up. The higher the speed, the greater the vibration, and the longer it would last.

Again, if the wheel is not dead true in its bearings, vibration would occur without moving the handle-bars at all. Anyone who has had experience of the destructive effect on the bearings of a large untrue flywheel will readily confirm this fact. S. LATOUR HORDLE.

COMPLEXIONS.

Sir,—Now that the cold winds are upon us again, we lady occupants of sidecars have seriously to consider our complexions, and from the various uncomfortable means that I saw used last winter I think a hint would be acceptable to many. The loose gauze veils often worn really cause serious chafing of the skin, and an ordinary net veil alone is of little use, but I find that if one first ties on *tightly* a fairly thick Russian net veil *under* the hat, and then drapes *over* the hat a loose gossamer motor veil, this may be lowered when driving and the under veil prevents any chafing. I have driven all day with this arrangement, and find it an admirable protection in every way, but the net veil must be tight. Now, a word of warning to my younger sisters—"flappers" I believe they are called—do not persevere unveiled when the wind blows from the north or east, or you will rue it later. W.M.D.

Golders Green.

SIDECARS IN THE SIX DAYS TRIAL.

Sir,—Our attention has been drawn to the statement which recently appeared in our announcement to the effect that the Triumph was the first single-cylinder sidecar combination to gain full honours in any Six Days Trial.

This claim was made quite in good faith—in fact on the strength of a report contained in the motor cycling press.

We regret the error that has crept into our announcements, as both Messrs. the James Cycle Co., Ltd., Birmingham, and Messrs. Bradbnry Co., Ltd., Oldham, assert that a similar performance has been achieved by one of their machines in previous trials. It is not our wish to claim any performance that is not rightly ours.

Will yon kindly give publicity to this in an early issne of your paper? TRIUMPH CYCLE CO., LTD.

JET SIZES.

Sir,—In reply to "C.T." in *The Motor Cycle* of October 9th, my Snnbeam has an Amac carburetter, and runs on 31 jet with a Terry vaporiser. I recently got 80 m.p.g. with this with three up—one in the sidecar, one on Tan Sad, and the driver (total weight 25 stone); this under normal running conditions. C. J. SIMS.

Sir,—In reply to "C.T.'s" qnery in *The Motor Cycle* for Octoher 9th, I would like to say that I have fitted a W.S.R. adjustable jet adapter to my Douglas, and am more than satisfied with the results. The workmanship and design of these little gadgets are without reproach.

Possibly "C.T.'s" valve timing is not right, with consequent "blow back"; otherwise, with the jet properly adjusted I am at a loss to account for his high petrol consumption.

By slight turning of the milled wheel an adjustment can be made practically to the corresponding makers' numbers of the jets required for each particular purpose.

If this meets the eye of any D.R.'s with whom I have made acquaintance, I should be glad if they would write to me. H. EVANS LEACH.

[Letters addressed c/o The Editor will be forwarded.—Ed.]

Sir,—With reference to "C.T.'s" letter in *The Motor Cycle* for Octoher 9th, *re* jet sizes, he asks for experiences with an Amac carburetter jet adapter (presumably, the W.S.R.). I tried this adapter on my 4 h.p. Douglas, with the results he stated, but on altering the level of the petrol I have obtained splendid results. I think that after a few trials with different levels "C.T." will not be disappointed with his purchase. I may add that I have no interest in the makers of the W.R.S. AN O.G.

Oxford.

TEAM PLACINGS IN THE A.C.U. TRIALS.

Sir,—There is a small error in the provisional list of awards in the A.C.U. Six Days Trial. The aggregate marks of the Morgan team are given as 498. It was actually 520 —Morgan 185, James 174, and Greaves 161. The mistake arose becanse F. E. Jones (Ariel) was erroneously included in the Morgan team instead of F. W. James. Jones's score was 152, which, added to the totals of Messrs. Morgan and Greaves, makes 498. The mistake was pointed out at the time to an official and admitted, but doubtless there was not time to correct it. The prompt manner in which the returns were made is most praiseworthy, and will, one must hope, be followed by other clubs. This small mistake is not to he wondered at. The Morgan team was fifth, not seventh, and was second of the passenger teams.

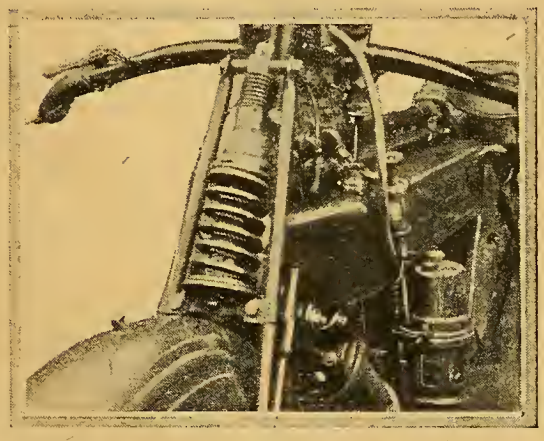
MORGAN MOTOR CO., LTD.

HONOUR TO WHOM HONOUR!

Sir,—I should like to make use of a little space in your valuable paper to express my appreciation of one of those firms that add a zest to the sport of motor cycling. At the beginning of the month I was stranded at a little place called Chilham, near Canterbury, on a Sunday evening. My chain was broken in two places, and I had no spare. My wife was with me, so I could not ask her to walk eight miles—the distance to the nearest town from which I could get a train. I had great difficulty in getting the use of a telephone, hut you can imagine my disgust on getting through to a garage to hear a man at the other end telling me he could do nothing for me at that time of night. That aort of thing would have disheartened a less seasoned rider. However, by good chance, I hit on the number of G. R. Barrett, St. Peter's Street, Canterbury, and, though it was now past nine on a Sunday evening, he at once volunteered to send out a car. Having towed me into Canterbnry, the manager (I believe it was) rung up an hotel and secured rooms for us, then told me the machine would be ready as early as I wished next morning. Sure enough, at 8.30, in calling at the garage, I found the machine had been fitted with a new chain, the tank filled, and everything ready for me to continne my journey with the least possible delay. The A.C.U. met the claim for towing courteously and without grumbling. Usual disclaimer. G. L. ROBBINS.

STRENGTHENING SPRING FORKS.

Sir,—Perhaps the enclosed photograph will be of interest to you as an addition to a P. and M. spring fork fitted out in France. The spring (originally from a Crossley clutch) is nearly 3in. diameter, and is supported at the top by a turned phosphor bronze bush, resting against the head-piece and shouldered to fit the spring. At the bottom is a steel plate, also shouldered, resting on the crossbar of the forks. The original main spring is retained, and runs through the centre of the lot.



The auxiliary springs fitted to R. W. Payne's P. and M.

The idea successfully prevented a tendency of the forks to "crash" on bad *pavé*. R. W. PAYNE.

THE A.C.U. TRIALS.

Sir,—Referring to the 1919 Six Days Trial, one cannot help noticing, with regret, what a very poor percentage of British-built motor cycles entered for this famous event. We are told in the motor cycle press that the A.C.U. Six Days Trial is organised for the purpose of showing the public, as a whole, the latest models and improvements in motor cycle design, and also to *prove their worth* in reliability and hill-climbing. We heard rumours of weird and wonderful designs to be kept absolutely secret until this event, but the result ia most disappointing—I do not think one machine could show anything at all startling or revolutionary in design.

On page 317, in your issue of the 18th ult., a list is given of the competing motor cycles, and I can only connt twenty-eight different British makes. Upon making an observation in the advertisement columns of the same issne, however, I count no fewer than eighty odd different machines of British make. Why, then, have so many manufacturers failed to show us what their motor cycles can do? Where were such well-known makes as the Bradhury, Premier, Brough, New Hudson, Singer, Williamson, Rudge, N.U.T., etc.? Where, also, were the lightweights—the Calthorpe, O.K., Allon, Ivy, etc.? Some members of the puhlic were doubtless waiting to see how these machines behaved, but they have been disappointed. Is the lack of entries due to fear of failure, mechanical or otherwise? Surely not. Were manufacturers unable to produce their latest model in time? I doubt it. In my opinion, the reason is that manufacturera are so overwhelmed with orders that they *will not be bothered* with entering for *the one* event of its kind in the year. E. MEESON.

COMPETITIONS.

Sir,—I do not agree with your leader in the issue of October 9th that open events should be open only to professional riders. It is quite true that the reputation of a machine may seem at times to suffer through "bad amateur performances," but, nevertheless, the manufacturer should welcome the amateur with open arms. In the first place, a number of amateur entries is an indication of the popularity of a machine and the trust which its owners place in it. Moreover, although the public are no doubt interested to know the best that a machine can do, they are at least equally interested to know what it may accomplish in the hands of amateurs like themselves. Also to bar the amateur brings in the old difficulty of the definition of "professional." The public should consider the successes of a machine rather than its failures so long as amateurs are allowed to compete. The failures may be due to faulty driving, but the successes can only be attained by the excellence of the machine.

H. GEORGE MORGAN.

WEIGHT OF LIGHTWEIGHTS IN THE SIX DAYS TRIAL

Sir,—The adverse comments *re* weight of 250 c.c. lightweights in the Six Days Trial seem to me to be quite unreasonable. It should be borne in mind that the weights included all accessories, tank full of petrol, lamps charged with carbide and water, and oil tank full; all spare tools and everything necessary for a long tour.

The performances of these machines in the trial prove that they are capable of doing the ordinary work of a motor cycle. Now what weight is to be cut? How can it be done when comfort, cleanliness, and utility are necessary? Of course, design and better material are slammed in front of us, as if we did not know anything about them or were too lazy to trouble. The fact is, experience shows where weakness exists, and this is not all found out in a Six Days Trial. It generally takes years to prove whether a design is satisfactory. When a machine has stood the test of years, one feels confident that it is right.

A motor cycle frame is subject to all sorts of stresses, and deflection laterally usually results in skidding. Vibration from the engine and torque of the engine, due to driving, sets up further stress. The clumsiness or otherwise of the driving, and the falls and bumps it receives, all make it practically impossible to design a frame strictly from computation of stresses, hence reliance upon experience.

Cost of production is also a factor.

Engines cannot be reduced much in weight unless we are to speed them up, and this will bring along a whole batch of troubles to the ordinary rider.

Gears on the whole are not too heavy. Of course, if reduction in weight is the sole object, cut them out and lose utility of the machine. Weight can also be saved by reducing capacity of petrol and oil tanks. No rider, however, will agree with this as a good move. Lighter tyres can be fitted—and who wants them! Footrests instead of footboards will save about 2½ lb. Weight may also be saved by cutting down the following items: Mudguards, tools and spares, saddle, lamps, and other accessories.

I think that most riders will agree that the items mentioned are none too substantial nor any too comfortable at present; and we cannot see how the increased demand for greater comfort and more substantial fittings can be complied with if they are to be reduced a good deal in weight. Where then? I say it cannot be done yet, if the machine is to give satisfaction through years of use and be able to complete a Six Days course.

It is worthy of note that the lightweight necessarily carries equal weight to that carried on a heavier machine, *i.e.*, rider, tools, lamps with generator, speedometer, pump, horn, and repair outfit, etc. PERCY J. GOODMAN.

THE ADVANCING PRICES OF MOTOR CYCLES.

Sir,—There is a considerable amount of confusion in the minds of the buying public at the moment regarding the way that prices of motor cycles are apparently soaring without limitation.

It appears to the layman looking on from outside that manufacturers are thoughtlessly striving, without restraint, to attain the highest standard of charge that their customers will stand. Profiteering suggests itself, and dissatisfied grumbling results.

A careful survey of a few very apparent facts helps to clear the air of a considerable amount of misunderstanding, and clearly illustrates the conscientious endeavour with which the British motor cycle manufacturer has striven to produce an article to suit the pocket of his patrons.

The only basis upon which can be estimated the value of a present-day commodity is comparison with pre-war prices. We are already paying 100% or more advance upon our present food and household goods and chattels. The cost of everything is doubled. The reason is not difficult to trace. The war with its trail of waste has to be paid for. A slight advance in the cost of living heralds a demand by labour for higher wages. Higher wages mean higher cost of production, with a further advance in cost of all commodities.

This state of affairs has been developing for some time now, and, commonly known as the "vicious circle," has advanced the rate of wages to somewhere 100% beyond pre-war standard.

New motor cycles, in common with other manufactured articles, are produced from raw material extracted from the earth. These raw materials are actually as free as the air, with the exception of the cost of labour that extracts them. Here we begin to see light.

The cost of labour that extracts the raw materials is up 100%, the cost of labour that manipulates the material is up 100%, and the cost of labour that completes the work is up 100%. But has the price of finished motor cycles yet reached an advance of 100% over pre-war standard? The answer is decidedly "No." It is therefore fair to suppose that until this level has been attained prices will continue to soar.

Motor cycle manufacturers, when faced with the matter of post-war production, gamely tackled the problem of estimating selling prices in their works. Subsequently, where production has been attained by a few firms, it has been found that these prices have been seriously underestimated.

The makers of castings, tubing, components, etc., are repeatedly advising their advances; no definite basis can yet be arrived at, and daily strikes and other disturbing conditions arise. No wonder the lot of the manufacturer is difficult, and no wonder prices soar! The high water mark that suggests itself is double pre-war standard. When this has been reached, no doubt prices will stand firm.

There is, however, a gleam of hope for the future. When labour questions have been settled, strikes no longer occur, and steady production can be maintained, massed output will be possible, and a steady decrease in prices must surely result.

Lack of understanding causes confusion, and is unconvincing. A considerable amount of present confusion arises through manufacturers advertising prices when they have not yet reached production. Subsequent events will prove in many cases that these prices cannot hold good when deliveries commence. Comparison is made between these advertised prices and the advanced prices of manufacturers who are actually delivering the goods. The well-advised intending purchaser will bear these points in mind, make his selection, and place his order now before prices advance further, rather than risk disappointment through indecision.

F. ASLETT COULSON ENGINEERING CO.
FRED A. COULSON, Proprietor.

BOOKS AND MAPS FOR MOTOR CYCLISTS.

Issued in conjunction with "*The Motor Cycle.*"

	Price net.	By post.
"MOTOR CYCLES AND HOW TO MANAGE THEM." The standard handbook on the motor cycle—its care and management. Twentieth Edition. 286 pages. 400 illustrations ...	2/6	2/10
"HINTS AND TIPS FOR MOTOR CYCLISTS." Containing over 400 useful "wrinkles" and helpful hints in regard to motor cycles. Sixth Edition. (Second Reprint.)	2/-	2/3
"TRACING MOTOR CYCLE TROUBLES." A reliable system for tracing motor cycle faults and of remedying any trouble when found. Fourth Edition	2/-	2/3
"THE MOTOR CYCLE" ROAD MAPS. England and Wales. Scotland, London (showing roads into and out of London and avoiding London). Mounted on linen. Set of three, complete in case	4/6	4/10

Obtainable by post (remittance with order) from ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4, or of leading Booksellers and Railway Bookstalls.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Cylinder Dimensions.

(1.) Could you tell me the bore and stroke necessary for a 1½ h.p. two-stroke engine? (2.) Would it be the same for a four-stroke engine?—J.A.S.

(1.) An engine of 1½ h.p. should have a c.c. of about 175. A bore and stroke of 60 × 60 mm. would give you approximately this power. (2.) The same rating is employed for both two and four-cylinder engines.

3½ h.p. Sold as 5 h.p.

I answered an advertisement offering a 5 h.p. Indian combination, 1915 model, and forwarded the price asked. I found, however, on delivery that the machine was only a 3½ h.p. model, and I accordingly wrote the seller, asking him either to remit me a portion of the purchase money, or to take the combination back, as he had misrepresented it in the advertisement. He refuses to do either of these things, and states that his reason for taking this course is because he himself bought the combination as a 5 h.p. Your advice on the subject would be appreciated.—S.W.N.

We should advise you to place the matter in the hands of a local solicitor; in any case, insist on the seller accepting the return of the machine. You will be fully justified in doing this.

Cylinder Removal.

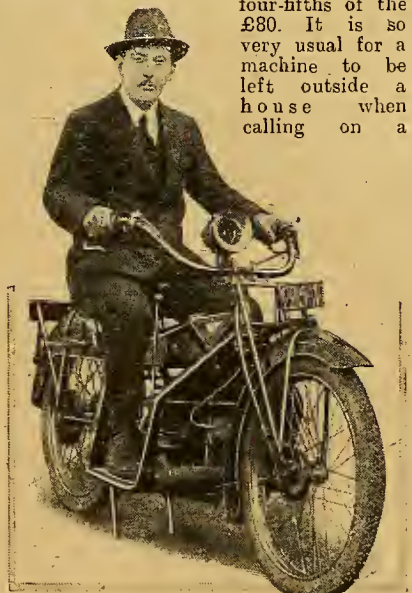
Will you please inform me: (1.) Whether a 1915 7-9 h.p. Indian has cylinders which can be removed for decarbonisation without taking the engine out of the frame, and is it an awkward job? (2.) After this machine has been going fast or up hills, the crank case gets so hot that I can only just bear my hand on it, and it cools slower than the cylinders. Is this right? It goes very well, but the front cylinder compression is not as good as the rear.—C.L.W.

(1.) The cylinders of the 7-9 h.p. Indian cannot be removed completely without taking the engine out of the frame. The cylinder heads, however, are detachable, and you can remove them for decarbonising purposes. (2.) The heating of the crank case may be due to conduction from the cylinders. It is possible, however, that the piston rings are worn, or that the slots have worked into line, and that a certain amount of the gas leaks into the crank case. Reasonable heating of the crank case is usual, and will not adversely affect the running of the engine.

An Unsatisfactory Insurance Transaction.

Having my cycle insured against theft, can I claim the full insurance, *i.e.*, £80, for which it is insured? The insurance company claim that it was negligence on my part to have had the machine stolen, and thus will not recompense me. The machine was stolen while I was calling on a friend, when I left it outside the house for about five minutes.—T.B.

The reply to your query depends upon the wording of the policy. If there is no average clause in the policy then the amount you would be able to claim would be the £80 you mention, provided the motor cycle is worth that amount or more, but if it is worth less, you would only be able to claim its actual value. If there is an average clause, and the motor cycle is worth more than £80, you would only be able to claim a proportion of your loss, according to the relationship the £80 bears to the value of the motor cycle, thus, if the motor cycle was worth £100, you would only be insured for four-fifths of its value, and would, therefore, only be able to claim four-fifths of the £80. It is so very usual for a machine to be left outside a house when calling on a friend that one would hardly imagine that any insurance company would regard it as an act of sufficient negligence to deprive you of your right to the insurance money.



Mr. Graeme Fenton, general manager of the French A.B.C. Company. Mr. Fenton, who is an Englishman, has spent most of his life in France, and is well known as a competition rider. He was formerly connected with Clement Frères.

Obscure Troubles.

Will you advise me on the following points? (1.) My sidecar pulls the machine over to the left to a painful extent. The wheels are upright, and the sidecar wheel is turned very slightly inwards. The sidecar axle is about three inches in front of the rear wheel hub. When I have no passenger, and put a hundredweight sack on the sidecar carrier, the machine runs straight. I have had the body moved two inches backwards, but this has had no effect. (2.) When engaging the clutch it refuses to take up the drive, unless the engine is running very slowly, which makes it impossible to start on a hill. If the engine is running fast, letting in the clutch makes no difference. When once going, I have no trouble; the clutch does not slip, and it is easy to change gears.—W.H.D.T.

(1.) The alignment of your sidecar appears to be in order, and we are therefore at a loss to suggest the cause for the difficult steering. You might try setting the sidecar wheel very slightly outwards, so as to bring it parallel with the motor cycle. (2.) In the first part of your query you suggest that the clutch is slipping, but later you state definitely that it does not slip. We think that as you are quite close to the manufacturers, your best course would be to submit your machine to their inspection.

Two-stroke Lubrication.

I have a lightweight two-stroke motor cycle. It is lubricated by a drip feed method, which is not satisfactory, as one cannot see the oil dropping when riding, it being fixed to the bottom of the tank, and when hill-climbing or going at high speed the engine overheats. Would the petroil system be satisfactory in this case, and what are the disadvantages of the system (if any)?—O.A.G.

We should not advise you to change to the petroil system, which is exceedingly messy, though it is otherwise satisfactory. A better method would be to fit a different form of drip feed of the Benton and Stone or Best and Lloyd type, in which the flow of the oil can be clearly seen.

Electric Lighting.

Will you kindly tell me what, in your opinion, is the best method of electric lighting for a motor cycle and sidecar (not dynamo)? Something cheap, as I do not run one motor cycle long. Is it advisable to convert gas lamps into electric.—L.B.

If you do not wish to use a dynamo, and only require the lamps occasionally, we should recommend an accumulator set. Gas lamps may be converted into electrics, and various converters are on the market for this purpose; they are advertised by many accessory houses.

N.S.U. Gear Repair.

I have an N.S.U. two-speed gear with adjustable pulley which is slipping on low gear. All the internal mechanism is in perfect order. I have had it down several times, and I might also mention that it is properly put together, but still unable to pick up drive in low gear—only screams.—H.F.

The N.S.U. gear does not usually slip badly on low. Possibly the low gear clutch plate is badly worn, or maybe the forked U piece having the inclined planes which withdraw the operating bolt is worn, or does not rise enough fully to engage the low gear clutch.

Licences and Taxes.

I am going to buy a second-hand motor cycle. Would you be kind enough to tell me how much I shall have to pay in licences, and where to obtain them?—W.W.

Before commencing to use a motor cycle it is necessary that it should be registered (5/-) and the Inland Revenue tax (£1) paid upon it. You should also hold a driving licence (5/-) yourself. Registration is effected by the local police authorities. The Inland Revenue tax is paid at the post office, and the driving licence is usually obtained from the same authorities as the registration number. You will get all the necessary information from the local municipal offices.

Compensation for Accident.

When going round a bend recently, I collided with another combination, the driver of the latter being on his wrong side. I had not a chance to pull up, as I did not see him until too late. As it was, I managed to swerve a little to the centre of the road, thus minimising the crash. He admitted his liability, inasmuch as he at once paid me a sum of money. I have witnesses to prove he was to blame. On getting an estimate for repairing my sidecar, I find it more than double the sum he paid to me. (1.) Can I claim the full damages from him? I gave him no receipt for the money. (2.) Could he claim the settlement to be complete, as I nominated the sum he paid?—W.E.C.

(1.) If the driver with whom you collided made a payment as compensation at the time of the accident, he certainly admits responsibility, and you will be able to claim the full damage from him. (2.) By the second question, we presume you mean that you are not entitled to make a further claim upon him, as you asked for a certain amount, which he paid you. We do not think that this has any bearing upon the settlement of the final claim unless you stated definitely on a receipt or otherwise that the money received was in complete settlement of your claim.

Fitting a Twin Magneto.

(1.) Would a 45° twin magneto fitted to a 50° twin engine work satisfactorily? (2.) Would it improve magneto to file 5° off one of the segments?—G.C.

(1.) It would be possible to use a 45° magneto on a 50° engine. (2.) You may find a slight alteration to the cams necessary, but we should advise that you first experiment by using the magneto as it is. In any case it will not be necessary to remove more than 2½° from the cams, and it would be best to take half of this from each cam.

Maximum Speed Attainable.

Would it be possible for a specially built racing motor cycle to attain a speed of 80 m.p.h. on a clear and level stretch of road? By "attain a speed of 80 m.p.h.," I mean to touch that speed in a spurt of approximately 300 yards, and *not* to maintain it for any length of time. Also, what is the maximum speed attainable under the same conditions?—G.E.M.

It is easily possible to obtain a speed of 80 m.p.h. on a specially built racing motor cycle. The maximum speed attained in this country is slightly over 93 m.p.h. for one kilometre distance, the machine used being a 7-9 h.p. Indian.

RECOMMENDED ROUTES.

CONGLETON TO HALIFAX.—W.P.A.

Congleton, Buxton, Chapel-en-le-Frith, Glossop, Dunford Bridge, Honley, Huddersfield, Elland, Halifax. Approximately 60 miles.

LEICESTER TO SCARBOROUGH.—I.M.

Leicester, Melton Mowbray, Grantham, Lincoln, Brigg, New Holland (ferry), Hull, Beverley, Driffield, Bridlington, Filey, Scarborough.

SOUTHPORT TO CAERPHILLY.—W.W.

Southport, Liverpool, ferry to Birkenhead, Chester, Whitchurch, Bridgnorth, Cleobury Mortimer, Ludlow, Leominster, Hereford, Abergavenny, Pontypool, Maesy-Cwmmer, Caerphilly.

NEWPORT TO BURY ST. EDMUNDS.—C.W.M.

Newport, Gloucester, Cheltenham, Stow, Chipping Norton, Banbury, Brackley, Buckingham, Stony Stratford, Wolverton, Newport Pagnell, Bedford, St. Neots, Cambridge, Newmarket, Bury St. Edmunds. Approximately 170 miles.

BIRMINGHAM TO LAKES (AVOIDING BLACK COUNTRY AND LANCS).—C.W.B.

Birmingham, Tamworth, Ashby-de-la-Zouch, Castle Donington, Long Eaton, Nottingham, Mansfield, Worksop, Doncaster, Ferrybridge, Sherburn, Tadcaster, Boston Spa, Harewood, Otley, Ilkley, Skipton, Gargrave, Settle, Ingleton, Kirkby-Lonsdale, Kendal, Windermere.

Avon Extensions.

The Avon India Rubber Co., Ltd., have recently opened new branches in Leeds and Belfast.

M-L Magnetos in the Six Days Trials.

Out of the 111 machines which started in the Six Days Trials, ten were equipped with M-L magnetos, and nine of them, representing five different makes of motor cycle, secured medals.

Triplex Goggles.

We have lately seen a pair of goggles which are specially suited to ladies' use, being fitted with an adjustable elastic band. They are made by the Triplex Safety Glass Co., Ltd., 1, Albemarle Street, London, W.1, and owing to their non-splintering qualities should appeal to motor cyclists of either sex.

The Rigby Gear.

Mr. E. J. Rigby, patentee of the Rigby selective clutch gear, designed to fit existing machines, has made arrangements for these conversion sets to be made by Messrs. Newcombe Brothers, automobile engineers, Zelland Road, Stockton-on-Tees. Particulars of these sets can be obtained on application to Mr. E. J. Rigby, Prescot Road, St. Helens, Lancs., or from the makers as above.

Wilkin Motors, Sheffield.

We regret that an error occurred in this column recently (page 380, October 2nd), when we stated that Mr. G. W. Wilkin, of Sheffield, had withdrawn his activities from the firm of Wilkin Motors. Mr. Wilkin actually owns the latter firm, and the business in which he has relinquished his interest is that of G. W. Wilkin and Co., which now trades under the style of Wilkins and Co.

Amalgamation.

We are informed that the businesses of Brown Bros., Ltd., London, and James Thomson and Son (Motor Factors), Ltd., Edinburgh, have amalgamated. Mr. J. Albert Thomson, chairman and managing director of the Edinburgh company, becomes one of the managing directors of Brown Bros., Ltd., while several of the London company's directors will join the Edinburgh board.

A Satisfactory Lubricant.

It is interesting to note, in connection with that portion of the A.C.U. English Six Days Trial which refers to the famous test hill, Bwlch-y-Groes, on which so many machines failed, that Rex Mundy on his Matchless combination, with a twelve-stone passenger, experienced no trouble whatever. Mundy was a gold medallist, and also received a fuel prize. He used Coolie oil throughout for engine lubrication, and found it entirely satisfactory, and had no trouble with any of the hills at any time during the trial, although his low gear was only 12 to 1.

MOTOR CYCLES FOR SALE.

A.J.S.

1919 A.J.S. Henderson, Elite sidecar, Lucas dynamo lighting set, spare wheel, mechanical horn, etc., as new; £180, or best offer.—Tomkinson, Clifford House, Crewe. [X5959

A.J.S. 5-6h.p. Combination, 1914, all accessories, just returned from makers after overhaul, in perfect condition; £125.—Maynard, 29, Lansdowne Grove, Neasden, London. [X6134

A.J.S. 1914 Combination, heavy tyres, speedometer, perfect condition, small mileage, Gloria sidecar, wind screen; any trial; £130, or offer.—8, Dysart St., Finsbury, E.C.2. [8969

A.J.S. 1914-15 6h.p. Combination, everything as new, tools, lamps, horn, speedometer, tyres perfect; £125; by appointment.—C.S., 6, Neville Court, St. John's Wood, N.W. [8942

1919 A.J.S. Combination, fully equipped regardless of cost, carefully driven by expert mechanic; any trial and examination here to prospective purchaser; 180 gns.—4, Oxford St., Lincoln. [X6299

A.J.S. Combination, 6h.p., 3-speed countershaft gear, chain drive, £16 recently spent on complete overhaul, enamel and plating excellent, tyres as new, Cowey, luggage carrier; £105.—3, Regent St., Rugby. [X4600

1919 A.J.S. Combination, not done 500 miles, lamps, horn, screen, spare wheel, etc., like new in every respect; what offers?—Apply, E. F. Rider, Rectory Farm, Low Catton, Stamford Bridge, York. [X4140

A.J.S. 1918, 6h.p., new April, 1919, spare wheel, Henderson Elite sidecar, wind screen, apron, Lucas lamps, Klaxon, mirror, condition as new; any examination; £155, no offers.—Knight, Farndon Fields, Newark Notts. [8695

A.J.S., 6h.p., 2-speed, countershaft, kick start, hand clutch, Phœnix torpedo coachbuilt sidecar, 3 new lamps, 3 heavy tyres just fitted, smart reliable machine; £80, or near offer; seen after 6 p.m.—140, Harley St., W. [9204

A.J.S. Combination, 6h.p., 3-speed countershaft, clutch kick start, Amac, Cowey speedometer, 3 lamps, horn, luggage and petrol carriers, stored 3 years, fully insured; best offer over £95.—Cookson, 12, Spring St., Trawshwhooth, near Manchester. [X6235

3h.p. 1914 A.J.S. and sidecar, smart, reliable machine, all-chain drive transmission, 3-speed countershaft gear, including hood, screen, lamps, sidear lamp, Stewart warning signal; the complete combination £110.—Wauchope's, 9, Shoe Lane, Fleet St., London. [9439

1916 4h.p. A.J.S. Combination, as supplied by firm, lamps, mechanical horn, apron, tools, in splendid condition, stored 2 years during war; expert examination and trial run invited; seen any time after 1 p.m.; price £115.—H. Perry, Lower Writhlington, Radstock, near Bath. [X6069

1918 Russian Model A.J.S. Combination, spare wheel, Easting wind screen, 3 electric lamps, perfect mechanical order and condition, 710×90 steel-studded tyre back wheel, 700×80 on others, practically new; £160; with complete insurance policy.—Haddon, North St., York. [8735

A.J.S. and Sidecar, 1918, military model, 6 weeks old, makers' guarantee, speedometer, D.A. set Easting screen, spare wheel, for sale after October 15th, absolutely perfect, extra tyre, tube, valve, and tools, best offer over £175; also £10 deposit on Premier super-runabout, offers?—Collins, 2, Water St. Rhyl. [X5796

Alldays.

ALLON.—Caffyns, Ltd., Easthourne, for delivery shortly. [0017

ALLON 2¾h.p., 2-speed, accessories, little used; £48.—3, Syr David's Av., Cardiff. [8756

ALLDAYS Matchless, 4h.p., 3-speed, clutch, C.B. sidecar, Bosch; £65.—7, Fieldway Crescent, Highbury. [9238

ALLDAY Allon, 2¾h.p., 2-speed, in perfect order; £46; fully equipped.—262, Blackhorse Lane, Walthamstow. [8885

ALLON, 2-speed clutch model, tip-top condition throughout, lamps, horn, tools; £50.—Parker's, Bradshawgate, Bolton. [X6191

JONES' Garage, special agents for Alldays Allon, Broadway, Muswell Hill, N.10, and Woodside Parade, North Finchley. [2931

2¾h.p. Alldays Allon 2-speed, 1916, tyres nearly new, engine perfect; bargain, £45; after 6 p.m.—189, Grove Lane, Camberwell. [8820

1919 Alldays Allon, fitted with Lucas lamps and horn, mileage 400; £75.—Charles Moxham and Co., 32, Torwood St., Torquay. [8800

1916 Alldays Allon, 2¾h.p., enamel and plate unscratched; bought combination; £38.—Hinton, Butcher, Mitcham Rd., Croydon. [9321

ALLDAYS-VILLIERS, 1915, 2½h.p., lamps, horn, fast; £35; Saturday after 1 o'clock.—27, St. Mark's Crescent, Regent's Park, N.W.1. [9124

ALLON 1918 2¾h.p., 2-speed, discs lamps, horn, full insurance till June, 1920, nearly new Palmer cord rear tyre; £60.—37, Montagu Rd., London, N.W.4. [9099

THINK—

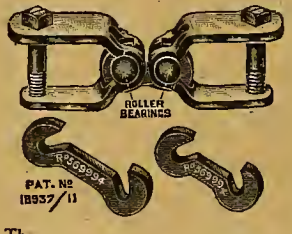
You are losing pleasure until you fit one of these belt fasteners—

Because, of course, you are taking unnecessary chances of an inconvenient breakdown. It is a matter of simple demonstration, drawn from the experiences of all sorts and conditions of motor cyclists, that these fasteners hold up for long years under conditions to which all other models have ignominiously and rapidly succumbed. Write us for more details, if you would like them.

The

FORWARD FASTENER—

The World's Best—has been used almost exclusively by all leading Motor Cycle Manufacturers. The best of all speed men have pinned their faith to it. Price, 1/6 each for ¾in., ⅞in., 1in., and 1⅛in.; 2/- each, exceptionally strong "Forward Giant," for 1⅛in. belts.



The

KING HOOK

Fastener fully deserves its title "King of all Hook Types." It was the first model of this pattern, and has yet to be beaten. Price, detachable, 1/-; adjustable, 1/3 each.

FORWARD SPARKING PLUG Co.,
Summer Row, BIRMINGHAM.

BOOT

REPAIRING

"Elite Holdtite Rivetless Soles."

Soles STUCK ON.—

We are now placing on the market an entirely new and Patented Rubber Sole. These soles are specially prepared with an adhesive surface, and fixed with Elite Holdtite Sol-fix solution. **We guarantee them to hold as firm as rivets or sewing.** The process of fixing is exactly the same as that of repairing a punctured Motor or Motor Cycle tube. One of the many great advantages of our process is that the Boots or Shoes when fitted with our soles become **absolutely waterproof.** Full instructions given with each pair of soles.

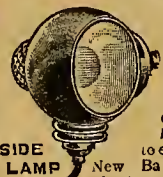
"VOLEX Dry Battery LIGHTING OUTFITS.

BRITISH MADE.

Volex Lighting Sets are the ideal, no-trouble outfits for the Motor Cycle and Sidecar. For over ten years they have been in use for this service, and of recent years, in consequence of their dependency, the demand is constantly increasing.

Dynamo Lighting Sets with Accumulators require careful attention and owing to complications have a tendency to go out of order. Accumulators, if not regularly charged, whether in use or not sulphate and become useless.



"VOLEX" DRY BATTERY LIGHTING SETS give no trouble whatever. The Battery, which is fitted in a metal container with switchboard mounted on top, lies conveniently in the bottom of the sidecar and with ordinary care will last, when in use, from six months to eighteen months without renewal. New Battery can be fitted in a few minutes at but little cost. The Battery case contains three separate Volex 4-volt Aero Dry Cells, with separate connecting boxes for the cables to Head, Side, and Rear Lamps. If one of the batteries becomes exhausted it can be replaced independently of the others. Unless specified, we always provide 4 volt Metal Filament Bulbs to each lamp, but 8 volt Bulb for Head Lamp will be provided where desired. **Complete outfit (as illustration), including Head Lamp, Ball Pattern Side and Tail Lamps, 3 Volex Aero Dry Batteries in metal container with switchboard, 2 Sets of Metal Filament Bulbs, and Waterproof Conducting Cords. Price £6/17/6**

Spare "Volex" Aero Batteries **15/- each**

CAUTION.—We would warn users that they may be offered substitutes for the "Volex" Dry Battery. No other battery will approach in reliability, durability, or capacity the British Made "Volex."

Sectional List, "VOLEX" DRY Batteries free on request.

UNITS of the above outfit.

HEAD LAMP, with switch and cord..... **32/-**
SIDE LAMP, with lamp holder and cord..... **18/6**
TAIL LAMP, with lamp holder and cord..... **13/6**
BATTERIES IN CASES, complete with waterproof conducting cord, to work in conjunction with own lamps.

Description	Price.
3 Volex "Aero" Batteries in metal container, with switchboard mounted on top, as illustrated	70/-

MOTOR CYCLES FOR SALE.

Premier.

PREMIER 1914 4h.p., 3-speeds and clutch, thoroughly overhauled, including new gears and clutch plates; £45, or offers.—J.A.H., Claybrooke Vicarage, Lutterworth. [X6367

1914 3½h.p. Premier, 3-speed hub, clutch, Bosch mag., lamps, wicker sidecar, perfect running order; £40, or nearest offer; seen any time.—Hammond, 6, Norbury Parade, S.W. [9137

Quadrant.

QUADRANT, 3½h.p., Bosch, B. and B., rebushed, re-enamelled, running order; £35, offers.—17, Lea Rd., Gainsborough, Lincs. [X5937

QUADRANT 3½h.p., new tyres, C.A.V., mag., speedometer, sidecar, accessories; £30.—Cooper, 9, Rochdale Rd., Plumstead. [8998

NEW 4½h.p. 1919 Quadrant Combination for immediate delivery from stock; £119.—Wanchope's, 9, Shoe Lane, Fleet St., London. [9444

Radco.

STANLEY RUSSELL, Newport, sole Isle of Wight agent for Radco motor cycles; delivery commenced. [4017

JONES' Garage, special agents for Radco, Broadway, Muswell Hill, N.10, and Woodside Parade, North Finchley. [2923

RADCO 1917 2-stroke, in first-class condition, only done 1,200 miles; £32.—Watson, 24, Broadfield Rd., Catford, S.E. [X6291

1919 Radco, 2¼h.p., 2-stroke, single speed, not done 20 miles, all accessories, perfect; £50.—Giles, 14, Milton Rd., Cambridge. [X6063

RADCO 1915 2½h.p., lamps, horn, etc., splendid condition, equal to new; £36.—Williams, 123, Fulbourne Rd., Walthamstow, E. [9350

RADCO.—Immediate delivery of 2¼h.p. standard model, £42/11; 2-speed model, £50/16.—The Premier Motor Co., Aston Rd., Birmingham. [9457

Rex.

REX 5-6h.p. Twin, fine condition; £38; fast machine.—97, Albert Rd., Croydon. [8970

REX Combination, old, not done 1,000 miles; £16/10.—352, High Rd., Willesden. [9400

REX, 3½h.p., mag. ignition, running order; any trial; £15.—Sharman, Carr Vale, Chesterfield. [X5921

6h.p. Rex, 2 speeds, clutch, handle starting, Bosch, B. and B., £35; sidecar, £6.—14, Phœnix St., Euston, London. [9062

4h.p. Rex Motor Cycle, splendid order, 2-speed, clutch, drip feed, new tyres; £56, or near offer.—7, Kenton Rd., Harrow-on-the-Hill. [X6022

3½h.p. Rex and wicker sidecar, wants overhauling, been standing 4 years; £15, or exchange lightweight.—H. H. Gaffer, Cotton, Stowmarket. [X5956

REX 6h.p. De Luxe, late 1913 combination, 2-speed, F.E., all fitments, spares, fast, powerful, sound, T.T. bars; nearest £66.—Hawell, Gosforth, Cumberland. [X6038

5h.p. Rex, 2-speed, free engine, handle-starting, new sidecar, smart appearance, 2 new cylinders and pistons fitted; £50.—Howarth, 39, Church St., Padiham. [9268

REX, 1913, 5-6h.p., 2-speed, H. start, clutch, lamps, etc., new tyres, tubes, and belt, splendid condition; £45.—F. Collins, Collingwood, The Causeway, Staines. [8902

6-8h.p. Rex C.B. Combination, under 7,000, tyres, accessories, excellent, fine appearance, spares, full insurance; must sell; first £65.—18, Northbrook Rd., Lee, S.E.13. [9274

LATE 1913 6h.p. Twin Rex, Bosch mag., 2-speed, Roc gear, handle starting, new Dunlop belt, just been overhauled; £45, or best offer.—Horswill, 42, Bridge St., Chester. [8897

REX Combination (1914), 6h.p. twin, Bosch mag., electric light throughout, perfect condition, hardly soiled, takes any hill, recently overhauled; nearest £100.—Barnes, D.S.O., 309, Cowley Rd., Oxford. [X5955

REX 6h.p. Combination, 1914, 2 speeds, free engine, excellent condition, just overhauled, hood, screen, lamp, speedometer, etc., not used during war, new heavy tyres; £95.—23, Schubert Rd., Putney, S.W. [9341

1913 6h.p. Twin Rex de Luxe, chain drive, 2 speeds, free engine, 3 lamps, horn, speedometer, tools, spare chain, tube, new Clincher Dreadnought on back wheel, the whole in good running order; £60.—1,014, Ashton Old Rd., Openshaw, Manchester. [X6279

REX, 1911, 4h.p. de luxe model, 2-speed and clutch, handle starter, with very smart and comfortable cane sidecar, engine just thoroughly overhauled and rebushed, the whole outfit re-enamelled as new, new tyres all round (2 Palmers, 1 Clincher de Luxe), complete with lamps and horn; examination and trial any time; £55.—11, Dalmeny Av., Norbury, S.W.16. [9314

Rex-Jap.

REX-J.A.P. 6h.p., 2-speed, free, Bosch, Bramble coach sidecar, Tan-Sad, 3 lamps, screen, perfect; £68.—17, Little Ealing Lane, South Ealing. [9405

A Motor Cycle Trophy for a Lightweight T.T.

WHEN, in 1914, we noted the weights of the machines which competed for the Junior T.T. of that year and found that they averaged upwards of 200 lb., we at once perceived that the genuine lightweight was being neglected in these races, for what had been a race of lightweights had no longer any title to be designated in such a way. Some of the machines, indeed, in the Senior event were little if any heavier than their smaller brothers in spite of their extra 150 c.c. That a 350 c.c. engine was able to propel a 200 lb. machine with its rider over the Isle of Man course at an average speed of 45½ m.p.h. certainly says much for its volumetric efficiency.

Realising, then, that more should be done for the real lightweight, and having its development much at heart, we decided to offer a trophy for a genuine lightweight T.T. race, to be held under the auspices of the Auto Cycle Union. This was accordingly done in 1914, but the outbreak of war put all matters of sport on one side, and at that time nothing was done. This year we renewed the offer, and, though the A.C.U. Competitions Committee were unable to see their way to accept a challenge trophy, on the ground that it would detract from the classic nature of the race, it was arranged that *The Motor Cycle* Trophy should take the form of a prize to be won outright "in the event of such a race being promoted by the Union." We are convinced that the trend of public opinion will force the hands of the A.C.U. to cater more for genuine lightweight motor cycles in 1920.

The details of the race have yet to be settled. A maximum capacity of 250 c.c. has been suggested (but it may be desirable to reduce this), and, as the object of the race will be to encourage low weight rather than small power, it seems to us that a weight limit should also be imposed—it might even be better to limit the weight rather than the engine size and allow makers to fit any engine they please within the agreed weight limit. It may be suggested that this would lead to machines being insufficiently strong for their purpose, but we do not think that manufacturers will imperil their reputations, to say nothing of the necks of their riders, by neglecting this very important point.

The A.C.U. Scooter Trial.

OUT of consideration for the present difficulties of manufacturers, the Auto Cycle Union has decided to postpone its proposed motor scooter trials for a month or two. The conditions governing the trial have not yet been completely settled, but it is announced that the trial will include tests for petrol consumption, slow running, and steering. An average speed of 10 m.p.h. will be required over a course of about fifty miles of normal main road. Further—and this is interesting, as *The Motor Cycle* has urged such a course—the scooters will be divided into classes by weight only, viz., under 60 lb., under 85 lb., and unlimited.

Such a trial would be child's play for some scooters and featherweight motor cycles, into which the scooter may conceivably develop. Even now there are genuine lightweight motor cycles which would come into the second class, and be capable of putting up a good performance under far more strenuous conditions.

It would appear that the A.C.U. trial is to be for scooters only, but, if weight is to be the limiting factor, it would surely be fair to include lightweight motor cycles, provided that they come within the stated limits. By so doing, direct comparison would be possible, and many valuable data gained.

A difficulty, of course, occurs in applying this suggestion to the unlimited class; but is a scooter of unlimited weight a desirable machine? The tendency for motor cycles is steadily to increase in weight, but a heavy scooter surely defeats the main objects for which these little two-wheelers are intended.

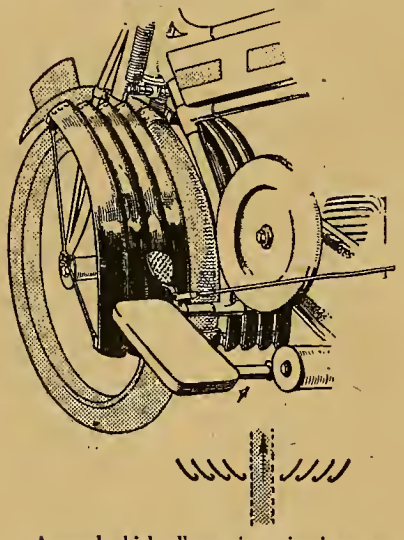
An Index to the advertisements in this issue will be found on the page facing the back cover.

IDEAS: Useful and Ingenious.

A Ventilated Mudshield.

MUDSHIELDS composed of a single sheet of material are apt to cause overheating of the engine by creating a vacuum behind them. To overcome this defect, I made a shield on the Venetian blind principle, and have protected the device illustrated.

The guard is fitted at right angles to the frame, and is made up of louvres, slightly curved, and formed with a gutter at the rear edge, which is adjusted at such an angle as to intercept mud, but allow a passage of air.—W. TALBOT.



A guard which allows air to impinge on the cylinders, but effectively protects the rider's legs from mud. A section is shown.

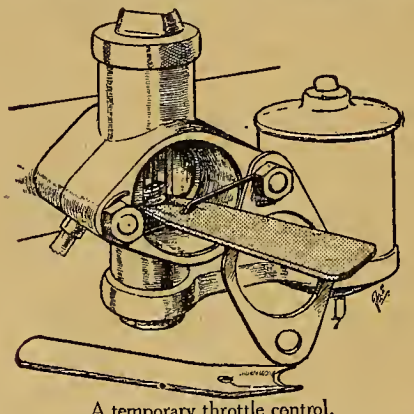
When a Throttle Wire Breaks.

THERE are several ways of getting home on these occasions. One often hears the tip to turn the air wire over to the throttle barrel; but this is not always possible, and, even so, the wire may be shorter, and the throttle barrel therefore opens so far that driving is next to impossible.

A recent failure of the control wire on a Douglas-Amac (exhaust jacketed type) was got over thus:

It was found that a thin metal strip wedged under the throttle barrel, through the main air inlet (gauze removed), gave just sufficient opening to run the engine quietly, approximately 15 m.p.h. on top gear. The end of the strip was filed out and bevelled to an edge. A small hole drilled and a wire passed through, bridging across the two securing nuts, formed a fulcrum for the lever and gave quite a good range of acceleration when needed, the throttle spring returning it to its nearly closed position.

This lever, very little trouble to make, can be carried in the kit, and ensures an easy "get you home" when means of wire



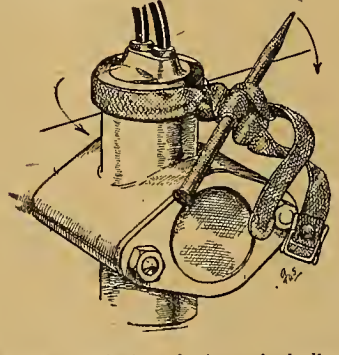
A temporary throttle control.

repairing are absent. It is preferable to plugging up the throttle to a fixed position and controlling by the exhaust lift lever.—J.A.S.

Makeshift Pliers.

OCCASIONS are many when a cap or nut which is usually loosened or tightened by pliers, needs removal and no pliers are at hand, or, as in the case in point, when the screwed cap over the throttle barrel of an Amac carburetter, which is normally only finger tight, had become immovable by the hand alone.

Take a carrier strap or stout cord, and with a centre punch, tommy bar, or other suitable rod, apply the strap *à la* tourniquet, around the cap, twisting it up until it grips sufficiently, when a sideway movement of the whole will start the cap.—J.A.S.

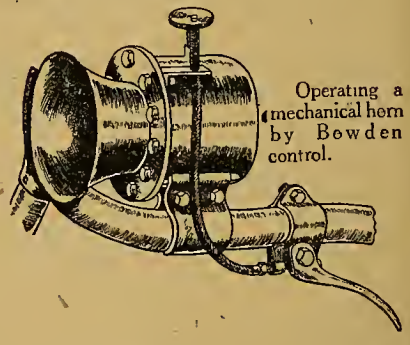


A strap as a substitute for large-sized pliers.

A Handle-bar Controlled Horn.

TO those riders who object to releasing the handle-bars when desirous of actuating the mechanical horn, the following arrangement will be of interest.

It will be seen that this attachment permits the operation of the horn without removing the hand from the grip. To carry out the conversion, a hole is drilled in the operating knob of the horn, and a small bracket fixed to one of the body screws to carry a Bowden stop. A nipple is soldered to one end of the Bowden cable, and a spring placed between the disc and the bracket. The wire is then passed through the holes in the knob and bracket, and connected in the usual way to a handle-bar lever, thus permitting the operation of the horn without releasing the bar or deflecting the steering.—F.H.B.



Operating a mechanical horn by Bowden control.

How to Make a Brown Paper Washer.

THE rider who removes his cylinder for cleaning purposes for the first time, and breaks the washer between the cylinder foot and the crank case, must often be puzzled to know how to make another one quickly and easily. This is no elaborate matter, as it does not entail working with compasses, squares, and a pair of scissors. It simply necessitates taking a piece of brown paper, approximately the size of the cylinder base, tapping it gently first of all round the edge with a light hammer. This tapping will cut the paper accurately and truly. The best type of hammer to use is a light riveting hammer. Having cut the paper to shape, it is then necessary to tap round the cylinder mouth, holding the paper quite still all the time, when a complete circle will be cut in a very short period. Lastly, turn to the holes through which the bolts protrude, and, if these are tapped with the round-nosed end of the hammer, the holes will be cut in the paper. It only remains now to soak the paper in boiled linseed oil and the washer is complete.

BY IXION

An Event.

IN the York M.C. climb up Sutton Bank a single-geared Baby Levis, of 198 c.c., surmounted the formidable hill at a speed which was little short of legal limit. The rider's name is unknown to me, and I am ignorant whether he is a trade crack, of the type that transports a specially readied machine to the venue by train, or whether he is the purest of amateurs, riding a stock machine bought through the ordinary channels, and tuning it without factory assistance. At any rate, the feat, in either case, is one which merits more attention than it has yet been given. I remember what trouble this same hill occasioned the late Ivan Hart-Davies a few years ago on a single-geared 500 c.c. four-stroke. I remember, too, that my own single-geared Levis of so recent a date as 1913 usually recognised its Waterloo after a few hundred yards of 1 in 9, taken with a rush. This feat is pleasant evidence of the increased efficiency of modern engines. If it was achieved by an amateur on a stock machine, it augurs well for the future of ultra-simple lightweights and scooters: given a weatherproof transmission and such an engine, the cheap runabout machine would satisfy a multitude of purposes. Moreover, such deeds of derring-do may silence the foolish people who talk as if tourist motor-cycles still conked out on long stiff gradients.

Objections to Overhead Valves.

THE advantages of overhead valves are mostly technical, and their disadvantages are mostly practical; this is surely sufficient explanation for the trade's reluctance to graft them upon our engines. The overhead valve gives a fractional increase in efficiency: other things being equal, the o.h.v. engine is either slightly more powerful or slightly more economical, as its designer prefers. These points are of comparatively small account in commerce, since few riders ever run their engines all out, or keep a close record of their petrol consumption. Add the cost to a firm of changing its patterns, and it is clear that no maker will change his valve design without strong inducements. On the other hand, overhead valves are by no means free from objections. They do not fracture and smash up the engine, as many Doubting Thomases fear. But they add to its overall height; it is already something of a squeeze to get the 500 c.c. engine into a popular type of frame, and o.h.v. can only be accommodated by fitting a shallow tank, scalloping out a clearance recess in one side of a deep tank, or using a high (and therefore heavy) frame. Again, there is a distinct, though probably unreasonable, prejudice against inaccessible valves; and o.h.v. may be regarded as inaccessible unless they are fitted in a detachable head. But makers cannot trust the average rider to restore a gastight joint at his cylinder head after decarbonisation: so most of them prefer side-by-side valves. On the other hand, I will venture a prophecy that we shall not see many side valve engines in the next T.T. In previous T.T. races the side valve has been common, because victory might reasonably be expected if an entrant possessed a good jockey, a fair share of luck, and a machine which would go the course without breaking down or losing tune. In the next race there will be so many entrants entitled to score on these grounds that most people will snatch every asset within reach; and I think the o.h.v. will not lightly be turned down by any aspirant. After that, of course, the knuts will all want "T.T." engines, and I suppose the trade will comply. What the knut wants to-day, John Citizen wants to-morrow: and so o.h.v. will threaten to swamp touring mounts in due course.

A Hotstuff Engine.

I AM at present trying out a non-standard engine designed for ultra efficiency, and it is an illustration of the case presented in my last paragraph. Its "cylinder" is actually composed of three separate portions bolted together, viz., a barrel, a head, and an exhaust valve chamber. I do not find it too easy to maintain full compression with two annular joints in the combustion chamber to be kept gastight, and no sane designer would put such an engine on the open market. Moreover, in the interests of light valves, overall engine length, etc., the valve springs are innocent of caps and cotters, the outer tip being bent in to form a diameter of the coil, and threaded through a hole in the valve stem. This system could never be used commercially with powerful racing springs. It is quite possible that this engine could hold its own in any company; it is much more than possible that any firm which marketed it would lose money.

The Cost of Acceleration.

I HAVE just bought a new tyre. This trite information is justified by the causation of the incident. I did not scrap the old back cover because it had burst or because it had worn down to the canvas. I scrapped it because I had sinned grievously and frequently in the matter of accelerating my engine violently. The destroyed tyre was fitted to the rear wheel of a machine adorned by an engine to which revs. were second nature; on a low gear it would do its 4,000 r.p.m. and all but double the legal limit. Consequently, when I struck a steep hill knuckle, I was very fond of changing down and slamming the throttle wide open. When I committed this crime on a steep, hard surface, I could always feel the back wheel struggling to get a grip: it always reminded me of my pet greyhound trying to get footgrip on a gravel path after a cat whilst revving freely. In my case

Occasional Comments.—

the tyre paid. The walls were sound. The tread of the tyre for the most part still showed plenty of rubber. But at brief intervals in the worn centre of the tread there were deep flint cuts, extending right into the casing or even through it. Such covers will become frequent spectacles in tyre repair shops as the modern revving flat twins get on to the market. Of course, if an owner can afford to eat up tyres like this, there is nothing more to be said: but I warn the impecunious that a jumpaway uphill with a willing engine is unco' bad for the rubber tread of the back tyre.

The Invaluable Haversack.

SINCE demobilisation, I have learnt that an ex-Army haversack is quite the most precious accessory which a motor cyclist can own, and I marvel greatly that Hunt, or one of those ever-clever people who invent fresh needs for us and live by supplying them, never sold us all haversacks in the long ago. As every veteran rider knows, the predominant sensation of motor cycling is that one is cluttered up with a variety of small articles and has nowhere to put them. You go down to the golf links, and the wife presses you to buy her a gas mantle as you pass Snooks's. You are nearing home after the A.C.U. Six Days, and, with a stab at the heart, you recall that you faithfully promised to bring home a Belgian hare or two white rats for sonny. You go to pay a filial call on your aged mother, and reflect that, as she lives in a country cottage, you really ought to take her a slab of salmon. Whilst you are mending a puncture, you see some lovely apples just over the hedge and there is nobody about. Moreover, though the agent managed to coax the spare tube into that patent case, you will be blest if you can induce the damaged tube to enter its restricted area. You have just packed up everything after unseizing your engine and you spot two spanners and a pair of pliers lying on the turf at the road edge. Your hooter sheds its clip, or your lamp fractures its bracket. It is getting dark, and the charge of carbide in the generator is undoubtedly stale, and you have four hours to go; so you buy a pound of carbide. Araminta begins to grow rather peevish on her bracket and asks you to carry her muff or her gloves or her sports coat. All these and many other imaginable circumstances spell "Misery" with a capital M if you are riding your machine under ordinary conditions: but if your trusty haversack is slung round your shoulders, you can put ninety and nine oddments into it, and forget their existence until you dismount. I admit the scent of my haversack is becoming a trifle fruity after three months of varied usage, but I shall shortly give it a dowse with post-war petrol, which is warranted to hot-stuff any other fragrance in quick time.

Lawks!

THIS vulgar ejaculation was wrung from my plebeian depths when I studied the gear ratios of the machines entered for the A.C.U. Six Days. Practically everybody is well down into double figures on the bottom gear, the main exceptions being the Zeniths (5 h.p. with gears ranging from 4 to 8) and the Scotts, which disdainfully consider a 9 to 1 ratio adequate for any self-respecting two-stroke. One 500 c.c. sidecar outfit—a trade outfit at that—actually descends to a 21 gear, and 6 h.p. machines with gears approaching 18 to 1 are not unknown. Secretary Loughborough has properly put the wind up the boys this time. It is interesting to reflect that, seven or eight years ago, all the Scottish climbs—which Wales may equal, but not surpass—were calmly tackled by the veteran trial riders with emergency gears rather higher than the intermediate gears now adopted, the man who had anything lower than 7½ being considered something of a coward and a duffer. I am not against fear-nothing emergency gears by any manner of means; let the bottom gear suffice for climbing lamp-posts, since duffers will, sooner or later, need all the help that a gear box can give them. The main technical interest of the tendency is that it proves what modern engines will stand.

A group of the new Peugeot quadrillettes outside the firm's Parisian showrooms. The Peugeot is an attractive runabout of entirely new design, and built throughout on car principles. Tandem seating is adopted. The engine, which is rated at 6.2 h.p., has four water-cooled cylinders of 50 × 85 mm. bore and stroke (668 c.c.)

The Lucas Magdyno.—

just as efficiently. The only part absolutely common to the two instruments is the customary driving chain or other transmission gear between engine and magneto driving wheel.

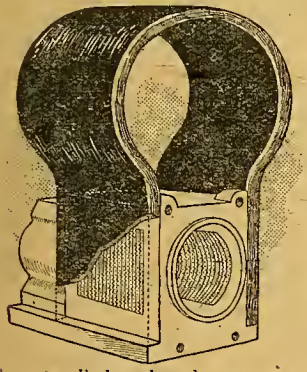
The Magneto.

The ignition part of the apparatus is a self-contained, weatherproof high-tension Thornton-Bennett magneto. Base-plate, armature tunnel, and contact breaker housing, form one piece, and contain laminated iron pole shoes (a striking innovation in magneto construction, originated in this country) around which it is cast, and the whole subsequently machined.

To avoid threads in aluminium, brass plugs are in-cast; in these the holding bolt holes are drilled and tapped, whereby the machine is held to its platform. Incidentally, the base-plate is of the same size as that of the average magneto, and will fit the usual platform provided.

A new type of contact breaker has been designed, which has entirely overcome the trouble of "the sticking rocker arm." The latter detail consists of a light pressing entirely filled with fibre, of which a large proportion projects and acts on the cam in the same way as the more usual small fibre heel on the rocker. Being properly balanced, only an extremely light spring is needed, and the effect of centrifugal force at high speed is negligible. A noteworthy feature is that the high-tension terminal carbon brush holders are at the same end as the contact breaker, and remote from the driving end of the instrument.

The magnet is a single piece of steel of a shape clearly indicated in the detail sketches, and by virtue of its large size is more efficient, and possesses the quality of remanence to a greater extent than

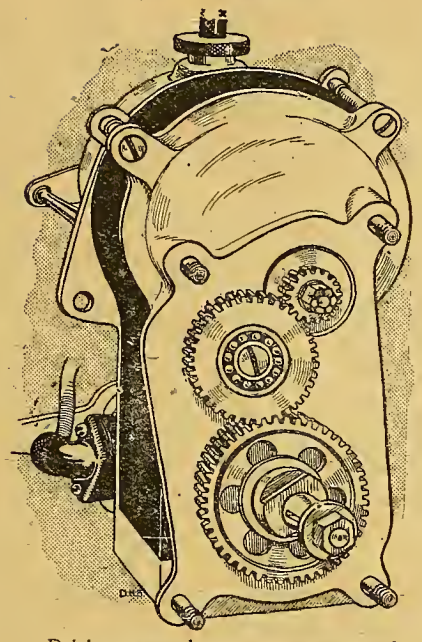


The peculiarly shaped magnet and the aluminium magneto base, in which the laminated pole shoes are in-cast.

smaller ones, so that the design of the magneto is actually improved by the mechanical consideration of housing the dynamo.

The Dynamo.

Current for lighting is supplied by a small replica of the larger Lucas machines, and this is housed above the magneto armature within the enlarged part of the magnet. The dynamo is cylindrical, having the armature eccentric to the casing, and its weight is but five pounds. The electrical output is from four to five



Driving gear between magneto and dynamo armature spindles. On machines where the former runs at engine speed an intermediate wheel is not used.

ampères at six volts pressure, and is maintained constant at high speed by the inter-brush method. The commutator and brush gear follow usual Lucas practice, and are particularly satisfactory, giving sparkless commutation at all speeds. Small spring-loaded triggers are provided to hold the brushes to their work, and no adjustments are necessary.

The drive from the magneto spindle to the dynamo armature is conveyed through a train of noiseless ball bearing gears enclosed in an aluminium case. Dynamo speed is one and threequarter times engine speed.

By slacking one finger screw and turning aside the strap over the commutator end cover, the dynamo may be instantly withdrawn.

Accumulators and Switch Box.

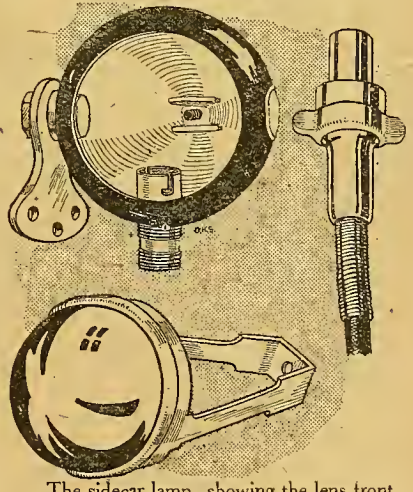
Two sets of batteries are provided, one for solo (two lamp) sets, and the other and larger for sidecar (three lamp) sets. Both are contained in neat metal cases adaptable to their particular purpose. The current is led by one combined cable to the switch box and electrical cut-out, thence to the lamps, and through a junction box to the batteries.

The switch box is designed to fit in a shell, which is intended to be soldered into the petrol tank. A small knob, capable of being turned in one direction only, operates the switch gear. There are four positions marked: lamps, off, charge, off. In daytime running, the switch is turned to "charge," when the current generated goes to the battery and is stored. Should the switch be inadvertently left in this position when the engine is not running, an electrical cut-out, contained in the switch box, breaks the circuit and so prevents the accumulators discharging through the dynamo. When the light is required, the switch is turned to "lamps," when all are illuminated.

For town work or when standing, the head lamp contains a two-filament bulb, which gives a small light when required by simply turning the bulb-holder at the back of the lamp.

Realising the disadvantage of a quantity of external wiring, the designers of the Magdyno set have evolved a scheme immediately noticeable in its elimination of non-essentials. While admitting the simplicity of the "earth return" system of wiring, certain defects were appreciated, and a neat compromise adopted. This is done by employing conductors on the concentric system, as follows: The wires to each fitting consist of the inner insulated member and an outer flexible metallic sheath, which provides a return path for the current. An enamelled casing material protects and enhances the appearance of the cables. All terminals are numbered, so that replacement is not a matter demanding electrical knowledge, and the termination of all the outer sheaths are soldered into bushes, thus providing good contact. In order to prevent chafing and cracking of the wires where they emerge from lamp-holders, they are encircled by a short length of springy wire coil, an unobtrusive detail, showing the attention bestowed upon minor points of design.

Designed to replace the ordinary magneto, the dimensions of the Magdyno are exceedingly compact, and, in most cases, it will instantly replace the existing ignition apparatus on standard machines, since the base plate, chain line, and height of driving spindle follow those of usual magneto practice. The weight of the dual machine is only 15 lb., so that the total addition of weight is negligible.



The sidecar lamp, showing the lens front detached. The latter is held by a triangular frame secured inside the lamp. At the right is a lamp adapter showing the protecting coil.

At the present moment the apparatus is not yet available to the general public, although it has been thoroughly tested under road conditions and gives an unbelievable beam. It will be largely produced for 1920 models, and there is a possibility that the makers, the Lucas Electrical Co., Ltd. (successors to Thomson-Bennett Magnetos, Ltd.), will make some definite announcement as to deliveries being made at the forthcoming Show. The above company is owned by Joseph Lucas, Ltd., Birmingham.

OVERSEAS SECTION

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

The Overseas Aspect of the Scott Trial.

PROBABLY no test throughout the course of the present year has more nearly approximated in its road problems to the conditions found in undeveloped countries than the trial recently organised by the Scott Motor Cycle Co.

We say this with full knowledge of the severity of both the English and Scottish Six Days Trials, and may quote the opinion of at least two riders who competed in all three that the course was more severe than anything in either of the big events, and that no man or machine could survive six successive days of similar severity.

The roads selected, and over which the greater part of the course lay, consisted chiefly of those mountain and moorland tracks which are familiar to all explorers of that part of West Yorkshire known as "the Dales." In bygone times, before the days of steam power, the turbulent mountain torrents of this region supplied the energy for the machinery of many a weaver, paper maker, and lead miner. Tortuous roads led over wild and barren moors to the little hives of industry where the workers' homes nestled around mill or mine in some sequestered dale. Times have changed, and the tide of progress has carried the flow of industry to the towns of the West Riding, leaving the old works high and dry.

To-day they are forgotten, and the tourist who loves unbroken solitudes, miles from rail-head and cities, ever and anon descends into nameless valleys, and finds these relics of a past industrialism, mostly silent and crumbling to dust, except here and there, where the old tradition and old processes survive in the hands of aged artificers, who fight a losing fight against the competition of modern methods and commercialism.

WHERE CHAIN TRANSMISSION SCORES.

One of the several watersplashes encountered in the Scott Trial. Many of the roads through the district wherein the selected route was chosen were never developed to the extent of bridge building, but occasionally the bottom of the streams would be firmly paved with boulders. Such definite obstacles, however, were overcome by the majority of the competitors.

A TEST OF FRAMES, FORKS, AND RIMS.

The Scar in Upper Nidderdale, one of the most desolate roads in Yorkshire. This *debris*-strewn track is only used by moorland sheep farmers, who follow a calling as lonely in degree as the life of any frontiersman on the outposts of civilisation. Triumph and Scott riders are seen negotiating this awkward stretch.

Pioneer Conditions existing in Britain.

THE old roads and bridle paths, at one time busy with the laborious transport of the district, are now silent and grass-grown, rivulets cross them, mountain rains have widened drainage gulleys, and washed away the soil from stony *débris*, leaving a surface of loose and shifting shingle, while outcrops of solid rock occur where the tracks breast the higher slopes.

The conditions, therefore, are those of a hilly district lately opened up by pioneers: in this case opened but to be deserted. The elementary paths are in process of reversion to the wild moorland whereon they were traced, and are now distinguished from it only by the stone walls between which they run.

For the motor cycle destined to be used in pioneer districts, this tract of country presents an admirable testing ground, and its popularity amongst the riders associated with the two designs of machines produced in Yorkshire no doubt largely accounts for the many points in which they depart from conventional practice.

❁ ❁ ❁

Where the Solo Mount Scores.

IN the Scott Trial almost all types of modern motor cycles were represented, from high-powered twins to lightweights, and to observe the manner in which they performed was illuminating in the extreme. A noticeable feature was that no one seemed disposed to enter a sidecar machine, even the 6 h.p. and 8 h.p. entrants preferring to face the test solo; indeed, probably nothing but a handy single-track machine could negotiate such a course in safety. A large part of the route consisted of grass road chiefly characterised by the three deep ruts clearly shown in one of the illustrations. Once in these, it becomes impossible to get out without stopping, and it was noticed that the footboard and footrest clearance on most machines was none too great. The advantage of the Triumph adjustable footrest hangers was here apparent, since most of the riders of this make had them rather high; and one or two canny riders of Scotts had removed the quickly detachable footboards of their mounts, and merely used the sprung cross-bar as a rest. In tight corners, such as were continually present on roads of the nature described, the hand clutch was found to be almost indispensable, and those whose mounts were fitted with tank lever controls to their two-speed expanding clutch transmission often found that they dare not release a hand from the steering to ease the grip of their gears. The foot control of the similar type of drive on the Scotts proved its worth under these circumstances, since, in conjunction with an engine equipped with a decompressor at all times available, and noted for smoothly accelerating from zero speed on a bad patch, the need for delicate clutch manipulation is practically eliminated. Of the water-splashes encountered, it may be said that, given careful and slow driving, the chain drive mounts were certain to cross without trouble, but the chain-cum-belt models invariably suffered belt slip. Magnetos appear to have reached a tolerable state of weather-proofness; and, while those fitted forward of the engines escaped trouble, the high and protected position adopted on the P. and M., Scott, and James made assurance doubly sure. Often trouble at watersplashes was due to baffling of the exhaust gas through the silencer outlet being under water, so that, in machines designed for this kind of work, it would be well to upturn the exhaust pipe at least above the level of the rear hub. Some of the riders,

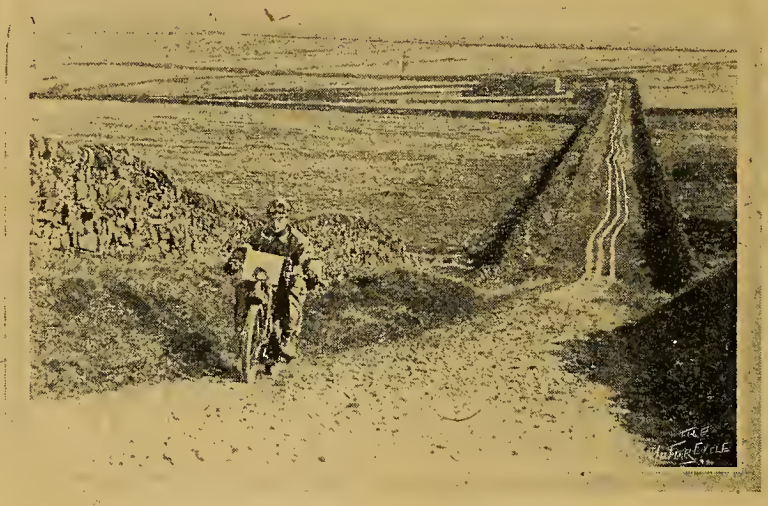
Overseas Section.—

being forewarned, temporarily arranged their exhaust systems to meet this eventuality.

Medium Weights Best.

The machines of from 500 c.c. to 600 c.c. undoubtedly proved the most successful, being not too heavy to be easily handled when surface and gradient reduced progress to a tussle between rider to keep going and machine to lie down.

The lightweights found their power and range of gear inadequate for the worst of the conditions, while the heavy twins chiefly suffered from their length of wheelbase proving awkward on abrupt bends, and from excess of weight above the centre of the machine. Large engines, too, despite their better torque, when revving idly on the low gear necessitated by the driving problems of abominable surface, have not the same steadying effect on the machine as the 4 h.p. type of engine pulling under moderate load, and it is indeed under the latter condition that the petrol engine works most satisfactorily.



A typical road on a moorland plateau. It is cut into three deep ruts by the heavy carts and sledges used by the hill-side shepherds.

The Best Specification Deduced.

To combine the good points of the machines which came through successfully would apparently result in a specification well adapted to perform under abnormal conditions of surface and gradient.

An engine of 4 h.p. to 5 h.p. for solo work seems most desirable, and should be of a type adapted to slow tugging, smooth acceleration, and not prone to be unruly when running light. A single-cylinder four-stroke or water-cooled two-stroke adequately fulfils these requirements. Frame design should be compact and strong, and a well-sprung seat and footrests are perhaps more desirable than complete springing. Ground clearance should be tolerably great, but is not so important in the line of the wheel track as outside it, *i.e.*, the footboards or rests should be high, or preferably capable of adjustment when required. Large tyres, strong rims and spokes, and substantial accessory fittings are a *sine quâ non*. The exhaust pipe should be well extended and upturned if riding is to be done in a torrent-intersected region. Riding position should be such as to give full power over the machine rather than extreme comfort; the saddle should be well within the wheelbase, the bars wide, forward, and fairly low. Gear changing and clutch control should not necessitate change of position nor release of the handlebars. The gears should be at least three in number unless the engine is extraordinarily flexible and capable of low-speed pulling, and should be changed by foot operation. The clutch, if separate from the gear, should be operated from the handle-bar. Carburation not unduly sensitive and a handle-bar controlled half-compression device are inestimable boons, whilst other practical points are large oil and fuel capacity, and the fitting of toolbags in sight of the rider instead of behind him.

OVERSEAS CORRESPONDENCE.

British and American Motor Cycles.

Mr. R. Berrill, Minbu, Upper Burma, emphasising the importance of spare parts, says:

"As an old reader of your paper, I have followed with interest the correspondence on the subject of the relative attractions of British and American motor cycles.

"Whatever argument may be advanced in favour of British machines, the difficulty of obtaining spares for them detracts considerably from their merit. This difficulty during 1918, and previously, may be explained on the score of the war being then in progress. There should not be much difficulty now. In regard to American machines, spares for them have been at all times easily procurable, and in consequence they are recommended. This question of spares is of greater importance than quality in the colonies, and British firms should pay vastly more attention to the subject than they have done in the past."

Backing up the British Manufacturer.

Mr E. Van Meerbeek, Brussels, writes: "As a motor cyclist of some experience, I have enthusiastically followed the movement for the last five years. The German invasion had made me cross the Channel and find new residence in London during the whole period of the war. Now back in Brussels, I realise to its full measure the value of your 'Colonial' column in which so many readers try to 'buck up' the English manufacturer. Certainly he has *not* studied the export trade and makes his machines to suit English roads—probably the best in Europe. Here we have that much detested *pavé*, and one might say, as for the Ford, that it is necessary to be followed by another vehicle to pick up all the nuts and bolts that have been shaken off. Here, too, the American has not been sleeping; his cars are rapidly becoming known. The invasion of Harleys, Hendersons, and Clevelands is developing quickly. All these firms *have full stock of spare parts* in their showrooms. Ford has on show his four-seater car, his lorry, *and his Fordson tractor!* Not one English firm has a single showroom in the town (so none in Belgium). Here and there one sees a B.S.A. on view in some garage window—that is all. Before the war, the N.S.U. and Wanderer were popular, as they had spring frames and automatic carburetters; so had the Indian. There is a good market for English machines here, as they are appreciated because of their popularity among the Belgian D.R.'s, who used nothing but B.S.A., Rudge, and James machines."

SUGGESTIONS FOR FUTURE SIX DAYS TRIALS.

Some Criticisms and Suggestions by a Practical Competition Rider.

ARE the results of the A.C.U. Six Days Trials really useful? As "a man in the street" I look for instructive and helpful information as a deciding factor in the purchase of a machine. What do I find? Very little of real instructive interest! I want to know the best machine fitted with the most efficient gears, engine, mudguards, and brakes, the ease of control, low petrol consumption, and also a most important accessory, the most efficient lamp.

I appeal to the A.C.U. Competitions Committee to give us a real six days test of the present-day motor cycle and its components and accessories, not a conglomeration of marks awarded for reading stop watches, while riding uphill, solo riding over roads of doubtful security, which no sane man would tackle at over legal limit, and a single brake test, which conveys no reliable information. All this is grossly unfair to manufacturer, machine, and rider alike.

For the sake of illustration, we will take the so-called "Consistency Driving Test." I am told this was to be a means of proving "the maintenance of tune" of the engine, from the beginning to the end of the week. Can anybody tell me who was responsible for this brain wave? I should like to put him on a machine, give him a split second stop-watch, and tell him to ride up a hill, two miles long, wet or fine, and "clock in" at the top—position unknown!—within seconds, on pain of losing his head.

Manufacturers and private owners are asked to enter their machines and pay high fees to accomplish a trick, like the "C.D.T.," to prove the reliability of their machines. Was there anything ever so farcical?

The Information Wanted.

Take another illustration of awarding marks. I am, I believe, right in thinking that the silence of machines was taken on the same hill and at the same time as the rider was engaged in the "C.D.T." All credit must be given to our friend Dr. A. M. Low for his fascinating little instrument the audiometer, but could he not have chosen a place when machines were being driven under normal conditions, and, furthermore, without the knowledge of some of the competitors as to his rendezvous? This is another instance of lost marks which is apt to mislead "the man in the street," and so we go on under the present conditions of carrying out a six days reliability trial for motor cycles.

Can we not devise for the next Six Days Trial better conditions, fairer methods, and a more instructive test? Let us have a six days test of machines, with their components and accessories divided into separate tests, and sectionised as follows:

1. Accessibility and kick-starter test.
2. Petrol and oil consumption.
3. Mudguarding.
4. Brakes.
5. Lamps.
6. Sidecars and their fittings.
7. Silence.
8. General comfort and ease of control.
9. Tyres and their non-skidding devices.
10. Reliability with nominated gears.

How to Obtain It.

Under the above sections it should be easy for the A.C.U. to organise tests, far less costly to themselves and others, and give valuable information to all concerned, and form a real guide to the potential buyer.

With tests sectionised as described, officials, observers, timekeepers, etc., would be reduced, no elaborate arrowing of the course each day, as many of the tests could be carried out in a limited area, as I will endeavour to show.

1. Could be done in a hall or garage, competitors being expected to dismantle and replace certain parts in a given time. Afterwards machine to be started with kick-starter.

2. To be incorporated with No. 10, and needs no words of mine as to procedure necessary.

3. A prepared surface to test efficiency of mudguards. Competitors to ride on this surface at varying speeds.

4. A technical test, and a test in the reliability section to prove road efficiency.

5. Tested in a dark room, each lamp to render signs legible at certain distances, and to burn continuously for six hours, and then a further reading test.

6. Ease of fitting and detachability, and passenger comfort and luggage capacity.

7. To be taken at stipulated engine and road speeds.

8. At judges' discretion.

9. A prepared greasy surface to test all non-skid devices and non-skid pattern tyres.

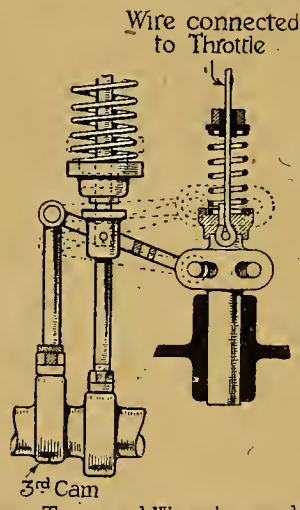
10. This test would be practically the only road test during the six days, and would comprise petrol and oil consumption on a circular course of twenty-five or fifty miles, to the distance of 150 to 200 miles, with good hills included, gear ratios nominated by A.C.U., a slow and a fast climb. Should a competitor fail, another attempt allowed; failure on second attempt to disqualify for reliability test. Punctures not to count against a competitor.

I would further suggest that certificates be awarded to all, showing the results of the tests, with a possible award for the reliability section, petrol and oil consumption, and the slow and fast hill climb in each class. In my opinion, a six days test, carried out on similar lines as described above, would be of real use to the buyer, and, in addition, the manufacturer would at all times have definite proof under the seal of the A.C.U. of the merits of the chief talking and selling points of his machine. THE MAN IN THE STREET.

RECENT PATENTS.

REVIEWED BY B. H. DAVIES.

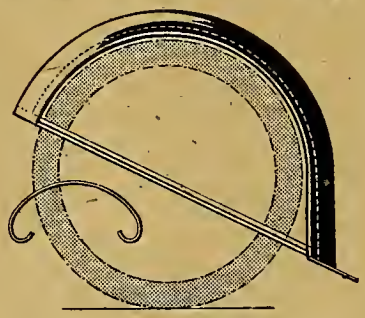
IF we succeed in fighting off the invasion of American cars and cycles, we shall be up against fresh onslaughts from Japan, to judge by the number of patents now being filed from that country. Messrs. Tamura and Watanabe are up to date, in that they are out to perfect air-cooling. Their gadget consists of a third cam, designed to lift the exhaust valve during the compression stroke when the machine is coasting. This cam operates a tappet, which actuates the exhaust valve tappet by means of a link-rod; and the third tappet is brought into contact with its cam whenever the throttle is shut by means of the wire shown on the right of the sketch. The patentees suggest that the following cycle occurs when descending a hill with the throttle shut:



Messrs. Tamura and Watanabe, cam design. No. 119,859. 5/3/17.

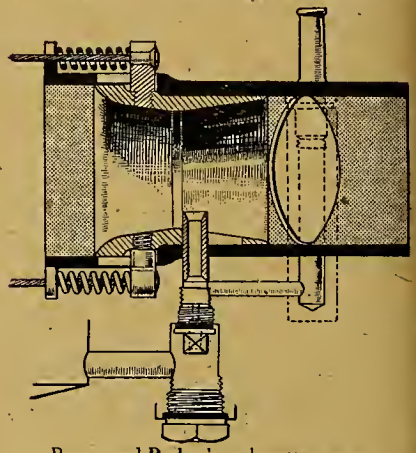
SUCTION STROKE.—Inlet-valve opened, as usual. Pure air inhaled. COMPRESSION STROKE.—Exhaust valve opened by the third cam. FIRING STROKE.—Inlet valve opened automatically by vacuum. Pure air inhaled. EXHAUST STROKE.—Exhaust valve opened as usual. Thus, they hold that a double scavenge of pure air will be obtained, and this air is not heated by any compressions, but is used solely to conduct away heat from the interior of the engine. I question whether the 60 lb. racing spring on my own inlet valve would open on the "firing" stroke; I rather think this stroke would suck up a lot of oil past the piston rings. But perhaps they have not got as far as 60 lb. springs in Japan.

Lt. Job is certainly a man of ideas. As the drawings indicate, he propounds what a florist would term an incurved mudguard. The wheel flings mud and water into the channels inside the guard, and the conduits shown along the sloped diameter in the larger sketch conduct the drainage from the front half of the guard to join the remainder of the filth at the rear end, where it is all harmlessly tipped on to the road. The channels can easily be cleansed by a hooked scraper, and very little water should be deflected outwards from the edges of the guard and blown back on to the rider. I should like to see this guard under test: it looks quite promising.



C. B. Job's improved mudguarding. No. 128,428. 8/17/18.

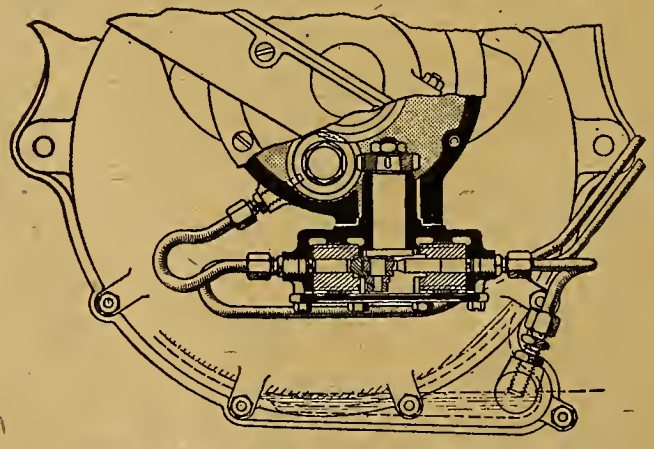
Messrs. Brown and Barlow have protected yet another carburetter, with which they hope to get such a range that it will win fuel consumption tests and also smash the flying mile record on Brooklands. It is of the straight-through type, and its main feature is a sliding choke tube. As shown in the drawing, the choke tube is slidably mounted and controlled by a pair of wires, a slot in the lower side clearing the jet tube. The jet tube contains at its base a submerged petrol delivery orifice, and is supplied with an adjustable release through the pipe shown on the right, which relieves the excessive suction on



Brown and Barlow's carburetter patent. No. 128,666. 30/8/17.

the submerged jet at high engine speeds. The choke tube may uncover an extra air port during its slide.

The Motosacoche people have given home manufacturers a lead, which, in conjunction with other lubricating innovations of recent date, may inspire our designers to abandon the hand pump and the "boa constrictor" system of giving the engine one meal of oil every five miles or so. A double-piston pump is driven by worm gearing off the crankshaft. Each piston works in a barrel drilled across a diameter of a cylindrical piece of metal which is free to oscillate. As each cylindrical member oscillates, the port in the heads of the barrel is alternately registered with the intake and delivery pipes. The left-hand unit of the pump draws oil from the tank, and delivers it under pressure to all bearings. The right-hand unit sucks at a pipe, of which the lower end dips into a catchpit at the bottom of the crank case, whilst the right-hand delivery returns surplus oil to the tank. The system is not a true "dry sump," since the scavenge pump

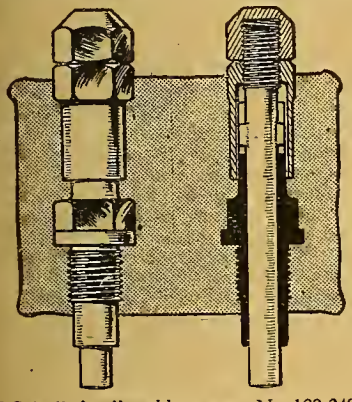


Motosacoche mechanical lubricating system. No. 127,224. 28/3/19.

Recent Patents.—

(right-hand) never drains the catchpit, but merely sets a maximum level to the oil. The cylinder is the only part lubricated by splash, and the depth of the sump increases towards the rear of the engine, so that the flywheels dip more deeply when the machine climbs. Every detail has been well thought out. A safety valve is provided in the main delivery pipe from the pressure side, and an easily detachable filter is fitted on the lead from the sump to the scavenge unit. Readers formerly connected with the R.A.F. will recall that the Le Rhône pump utilises the oscillating cylinder principle. This is a very pretty oiling system; no criticism is possible except on the score of expense, and there are few items for which motor cyclists will more gladly pay an extra sovereign than a thoroughly efficient and automatic lubrication system; moreover, such a system will pay for itself in one season by the reduced oil bills which it secures.

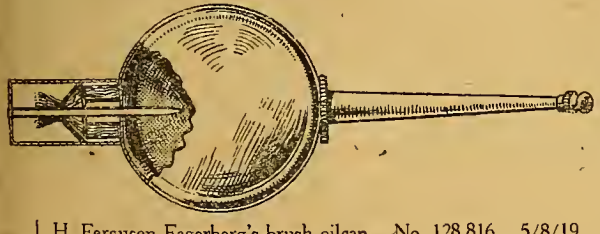
An excellent adjustable tappet is protected by the B.S.A. people. Lugs on the tappet engage slots inside the guide, and prevent rotation. The tappet head



B.S.A. Co.'s adjustable tappet. No. 128,249. 3/7/17.

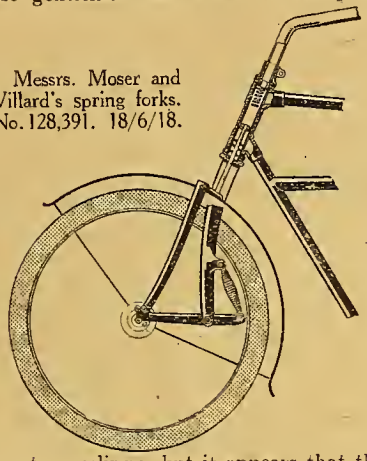
is adjusted by screwing it up or down the tappet, and the lower side of the locking nut is extended downwards in the form of a sleeve, which prevents grit from entering the guide.

Mr. Ferguson-Fagerberg has protected a brush oilcan. The cap at the left has a flexible end, by means of which pressure is applied to the contents; it also forms a separate compartment in which graphite powder can be placed. Underneath this cap is a brush, fed with oil from the main body of the can. You may either squirt oil from the standard nozzle on the right, or remove the cap on the left and brush chains over with graphited oil, as you require.



J. H. Ferguson-Fagerberg's brush oilcan. No. 128,816. 5/8/19.

When I saw the phrase "elastic fork" at the head of a specification by MM. Moser and Villard, of Grenoble, I thought these gentlemen had added a new peril



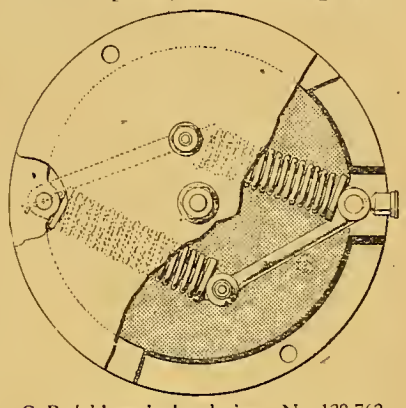
Messrs. Moser and Villard's spring forks. No. 128,391. 18/6/18.

to motor cycling; but it appears that the term is merely the *Entente Cordiale* for "spring fork," as the sketch indicates. The fork is very simple. The main shocks are taken through a horizontal lever by the coiled springs shown on the right. Excessive stressing of these springs in either direction is prevented by a piston connected to the auxiliary fork. This piston slides between two coiled springs inside the piston head, and is suitably shaped to prevent its jamming.

M. H. Pequignet, of Montreuil, proposes a valve system, which will puzzle novices. He employs a double piston valve to control both the inlet and exhaust port. This valve slides in a cylindrical casing machined in the cylinder head, and is internally cooled by oil. A coiled spring placed above the upper piston serves to keep the heel of a universally-jointed push-rod in contact with the cam, and to push the valve downwards as required. The cam is duplex, and runs at engine speed. As shown in the drawing, there are two grooves in the working face of the peculiarly shaped cam, and these grooves run side by side for practically an entire circle, except where the heel of the push-rod crosses over from one groove to the other, by what a railwayman might describe as some "X points." When the push-rod heel is in the groove of small diameter, the valve is at its lowest point of travel, and opens the inlet port. Rising to its mid-position, it closes both ports for the compression and firing strokes; finally, it rises on the maximum diameter of the cam path to uncover the exhaust port.

H. Pequignet, valve system. No. 128,870. 26/12/18.

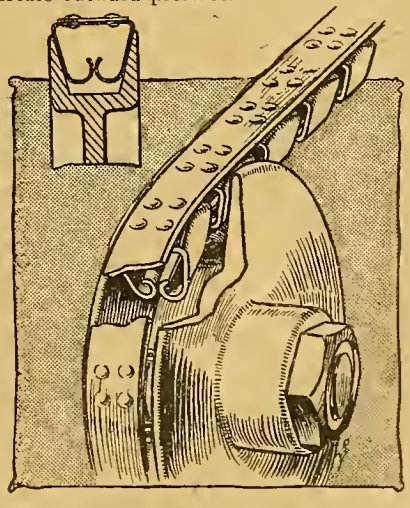
Lt. Job has devised a spring frame which deserves a little study. His system is concentrated at the axles, and the rigid forks terminate in steel rings, in lieu of the usual slots. These rings are enclosed between steel discs mounted on the wheel spindle, the disc being free to



C. B. Job's springing device. No. 128,762. 8/7/18.

slide upon the rings. Each ring is connected to its pair of enclosing discs by the double spring toggle joint shown in the sketch. The path of the wheel axle will be approximately an arc about the centre of the countershaft from which the drive is taken, so that the tension of the driving chain will not vary when the wheel bounces.

Mr. W. R. Keen is an engineer and I am not; nevertheless, I am audacious enough to suspect that his proposed transmission might prove noisy. He has the acumen to perceive that a belt drive is very nice when it neither stretches nor slips. So he has worked out the equivalent of a non-stretching, non-slipping belt, constructed entirely of metal. For the top run of his V belt he utilises a series of linked metal plates, comparable to a chain. Beneath these are secured V-shaped downward extensions, which are made of spring steel, so curved as to take an abutment against each other and create outward pressure.



W. R. Keen, patent belt. No. 128,775. 26/7/18.

Police Traps.

Riders are advised to exercise caution in passing through Croydon. Police traps are in operation where the ten-mile an hour limit exists

A police trap is also in operation on the Marlborough and St. Paul's Road, Bradford, and motor cyclists are warned not to exceed the prescribed speed limit in that district. Caution should be exercised, too, in Swansea and other parts of South Wales.

New Morgan Works.

The new works of the Morgan Motor Co. were opened on Thursday, October 16th, by a social evening and dance given by Mr. H. F. S. Morgan to his employees and some of their friends. The new works cover 38,400 sq. ft., and the total space now covered by the Morgan factory is over 50,000 sq. ft. Mr. Morgan is considering further extensions. For some years now, the Morgan has been popular in France, and arrangements are being made to produce the car in Paris for the French market only, under the direction of Messrs. Darmont and Badelogue, the French concessionnaires of the Morgan.

French Flying Kilometre Trials.

The Competitions Committee of the Automobile Club of France held flying kilometre speed trials on the road at Achères on the 16th inst. There were classes for motor bicycles of 250 c.c., 350 c.c., and 500 c.c., also a class for motor cycles and sidecars of 1,000 c.c. Péan, on a Peugeot, in the 500 c.c. class, made the fastest time in his outward journey, viz., 30s., which equals a speed of about 74½ m.p.h. As in our own flying kilometre trials on the road, competitors had to ride the distance of one kilometre in both directions, the average time of the two journeys being the recorded time. The results were:

250 c.c.—Alcyon I., outward 51⅕s., homeward 68⅘s., average 60s.; speed=37½ m.p.h.

350 c.c.—Alcyon III., outward 33⅗s., homeward 37⅕s., average 35⅘s.; speed=63½ m.p.h. Alcyon II., outward 34⅖s., homeward 37⅖s., average 36s.; speed=62 m.p.h.

500 c.c.—Peugeot (Péan), outward 30s., homeward 34s., average 32s.; speed=70 m.p.h.

Sidecars 1,000 c.c.—Harley-Davidson, outward 46⅘s., homeward 48⅘s., average 47⅗s.; speed=47¼ m.p.h.

Col. Holden's electrical timing device was used, and members of the A.C.F. Competitions Committee acted as officials.

Olympia Rendezvous.

At a recent meeting held by a few of the members of the late Third Army Headquarters D.R. Section, it was decided to visit the motor car show, Olympia, on the evening of Wednesday, November 12th, when it is hoped that other D.R.'s who were connected with or ran to them whilst in France will make an effort to be present for the purpose of meeting old comrades.

Spanish Road Race.

A road race, which carries with it the title of championship of Spain, took place on the 12th inst., over a distance of 404 kilometres = 250 miles. The winner rode an Indian, and completed the distance in 5h. 58m. 50s., which is equal to an average speed of nearly 42 m.p.h.

The second man, also on an Indian, averaged 38½ m.p.h.; and the third man, on a Motosacoche, 34¼ m.p.h.

In addition to the motor bicycle championship event there was also a sidecar championship over a distance of 264 kilometres = 164 miles.

Indian riders were first, second, and third in this event. The fourth man to finish rode a Motosacoche. The winner's time equals an average speed of 40½ m.p.h., which is remarkably good in comparison with the solo speed even when the shorter course is taken into consideration.

Special Features.

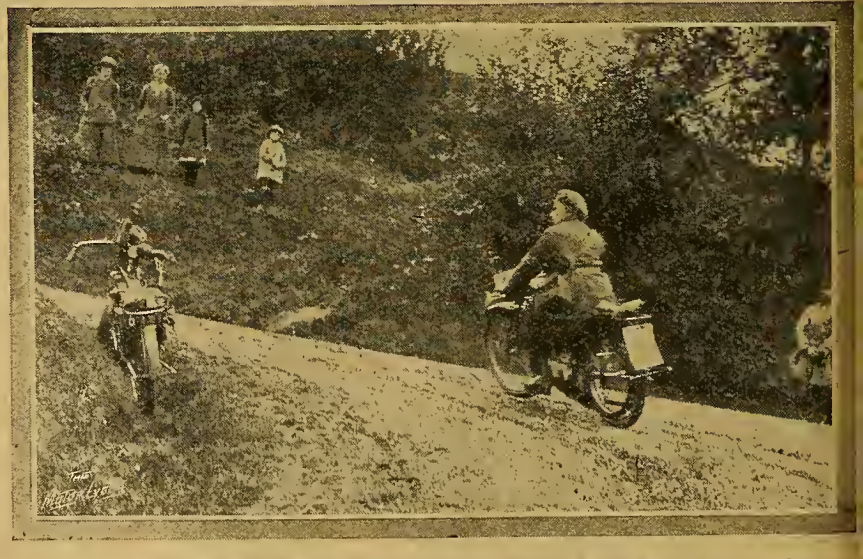
A NEW THREE-WHEELED RUNABOUT.
OVERSEAS NOTES.
THE RELIANCE CUP TRIAL.

Spare Parts for Motorists.

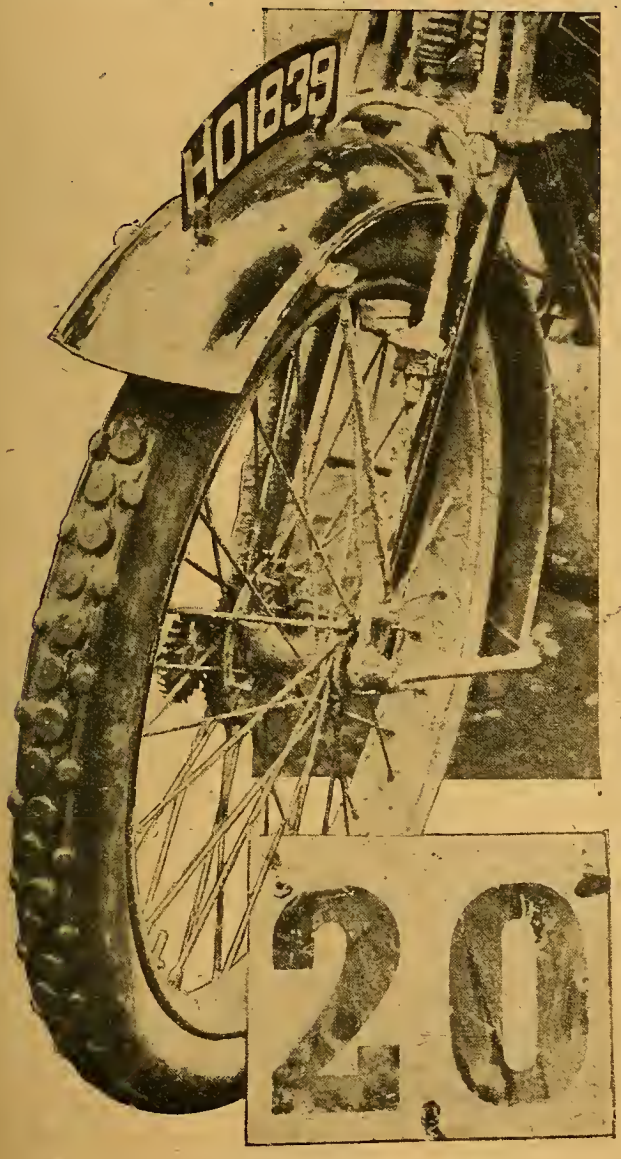
Motorists are experiencing considerable difficulties in obtaining spare parts, for the lack of which their vehicles are unusable. Some manufacturers have practically no stocks of spare parts, while others are still able to supply. The finding of a spare part by a motorist is a task calling for the expenditure of much time and patience.

Motorists requiring spare parts are strongly advised, if they are members of the Automobile Association, to communicate with the nearest of the twenty A.A. branch offices distributed over the country. During the past few weeks, as shown by letters in our correspondence columns, several members have been assisted by the Birmingham A.A. office, which has in some cases received requests for spare parts, and sent them to members on the same day. Where the required parts are not available, members are advised of the most economical method for getting them specially made.

Members residing in the Metropolitan area should communicate their requirements to the A.A and M.U. Engineering Department, Fanum House, Whitcomb Street, London, W.C.2.



B. Kershaw making a good ascent of Farlow Bank on a J.A.P.-engined 2¾ h.p. Verus. He was one of the two survivors in the recent "captain's run" of the South Birmingham M.C.C.



LOOK AT THIS PHOTOGRAPH!

THE A.C.U. TRIALS.

WHEN Dunlop rubber studded motor cycle covers are issued from the Company's works there appears in the centre of each individual stud a tiny "pip" of rubber: this is called a mould mark.

Look at this photograph. The tyre has just been through the whole of the Six Days' Trials, under the most severe conditions, and the machine to which it is fitted has secured for its owner a Silver Medal.

And the mould marks are as plainly visible as when the tyre left the works!

Taken in conjunction with the Trial results, which showed 63·63 per cent. of Gold Medallists on Dunlops, is anything more required to prove that the wearing quality of Dunlop rubber studded motor cycle covers is *superlative?*

TRADE MARK.

C

The CLYNO 1,800 Mile Trial

July 24th. Owing to a somewhat late start from Carrbridge, occasioned by our meeting one or two Scottish Trial riders, who had retired from the contest, we did not arrive at Lairg until 4 o'clock in the afternoon. After having had tea and engaged rooms for the night, we decided to tackle the journey to Durness and back in the evening.

We left Lairg Hotel at 5.30 and arrived at Aultnaharra without incident. But from here a positive nightmare awaited us. At Benhope we tried to cross the end of the Loch and to get on the old mountain road which leads to Erribol. The water, however, was too deep, and we were compelled to go round Loch Hope and Loch Erribol. The ascent of Erribol was accomplished by all of us easily, two of the machines running on second gear.

We then rode to Durness and Rhiconich in the twilight.

Never shall we forget the journey back from Rhiconich, via Laxford Bridge. The roads were appalling and the corners most dangerous. This was the only portion of the whole trial over which we did not average 20 miles an hour.

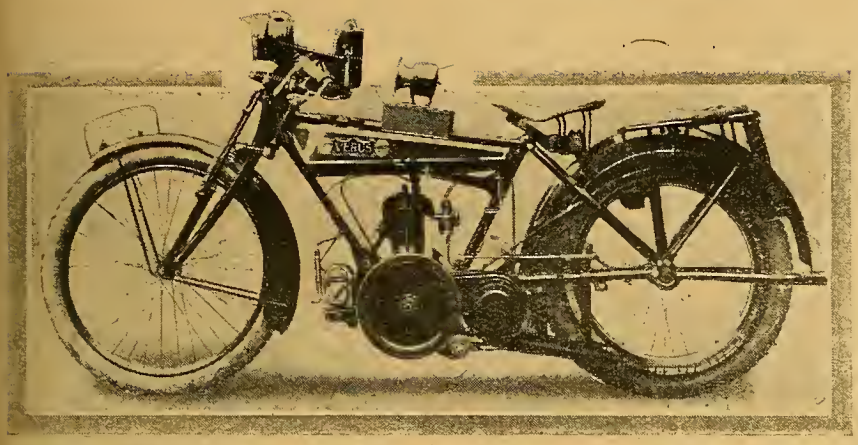
But all's well that ends well. We arrived back at Lairg at 2 a.m., all three machines having run splendidly and having done no less than 288 miles in the day.

We will talk about our Fifth Stage in the issue of Nov. 6th.

CLYNO ENGINEERING CO., LTD.,
PELHAM STREET, WOLVERHAMPTON.

546A

In answering this advertisement it is desirable to mention "The Motor Cycle."



The Blackburne-engined Verus—a new model which promises to be very popular next year. Note the metal tool box on the top tube. We hope to deal more fully with this make in the next issue.

A T.T. Winner Wanted.

A firm of high repute is requiring good riders for the next T.T. Race. Amongst demobilised despatch riders there are, no doubt, many qualified riders who are capable of putting up a good showing in this strenuous race. If any motor cyclist, however, with army experience or not, has the necessary credentials which might qualify him as a likely candidate, and will send full details of his experience to the Editor, his letter will be forwarded to the firm in question.

A Sound Opinion.

In adjudging a tricycle propelled by an Anto-wheel to be a motor car, the Lord Chief Justice said he was bound by definitions in the Statntes to regard a tricycle propelled by an Auto-wheel as a motor car, "though," he added, "if I had to decide for myself I should think it would be perfectly absnrd to call such a machine a motor car. In deciding that it is a motor car I cannot help myself. If I could, I would. This decision may raise other difficulties which have been pointed out to us by the respondent. He will have to carry side lights, and a number plate in front, and a number of things which are properly applicable to a motor car, but which by no effort of imagination can be considered appropriate to a carriage of this description."

Liege Race Meeting.

A race meeting organised by the Liège Motor Club took place on the 12th inst. Points were allotted for speed and regularity. The results of the various classes were:

250 c.c.—1, Pirlot (Clevcland); 2, Muller (Velocette); 3, de Weiz (Cleveland).

350 c.c.—1, Praillot (Baby Trinmph); 2, Feyens (Clyno two-stroke).

500 c.c.—1, Speedwell (Rudge); 2, Dehaybe (Sarolea); 3, Verlinden (Sarolea).

750 c.c.—1, Antoine (Triumph); 2, Vanderhugen (Triumph); 3, Lejeune (Triumph)

1,000 c.c.—1, Preudhomme (Harley-Davidson); 2, Vandewiele (Indian); 3, X— (Indian).

Sidecars 500 c.c.—Havart (Sarolea).

Sidecars 750 c.c.—Dandois (James).

Sidecars 1,000 c.c.—1, Springuel (Harley-Davidson); 2, Werder (Harley-Davidson); 3, Ummels (Excelsior).

Sidecars over 1,000 c.c.—Heinnerts (Reading-Standard).

Removing Indian Cylinders.

On page 467 of last week's issue of *The Motor Cycle* we mentioned, in reply to a reader's qnery, that the cylinders of a 1915 7-9 h.p. Indian motor cycle could not be removed without taking the engine from the frame. Several readers advise us that this is not the case, and that they have regularly removed theirs for the purpose of decarbonising and similar purposes.

We are, of course, bound to stand corrected, and our reply to the reader who sought our advice should have been put in this form: "The cylinders *can* be removed without dismantling the engine from the frame, but we do not recommend the practice to the average amateur."

It will be remembered that the Indian cylinders are held by long studs screwed into the crank case and passing out to the top of the detachable heads, which are secured by nuts. To remove the cylinder barrels it is necessary to unscrew one of these studs, and as these have no provision in the shape of hexagons or flats for spanner grip, and as they screw directly into the crank case, this practice is not desirable if carried ont nnskilfully. For well-known reasons, it is considered bad engineering practice frequently to remove steel studs which are screwed into aluminium, unless a special form of thread is used as in the Indian. Moreover, in the case described, the temptation for the amateur without proper workshop equipment or methods is to make barbarous use of some such tool as a plumber's pipe grip, often with disastrous results to the threads of the studs.

Temptation.

A novel attempt to obtain early delivery of a new model was recently resorted to by a customer of the Colmore Depôt. He insisted on paying a premium by enclosing a cheque for £10 for the Dunstan Home for Blinded Soldiers. Mr. Paskell, of the Colmore Depôt, could not, of course, resist so subtle a temptation to aid so worthy a cause, and it certainly offers one solution of the difficulty in taking premiums.

The Scooter Trial Postponed.

Owing to the present abnormal difficulties which are being experienced by the manufacturers of motor scooters, and in order that they shall not be unduly harassed, the Auto-Cycle Union has decided to postpone the proposed motor scooter trial for a month or two. There will be three classes of scooters qualified by weight only, viz., under 60 lb. (original tentative A.C.U. definition), under 85 lb., and unlimited. Further particulars concerning the trial will be published shortly.

THE MOTOR CYCLE

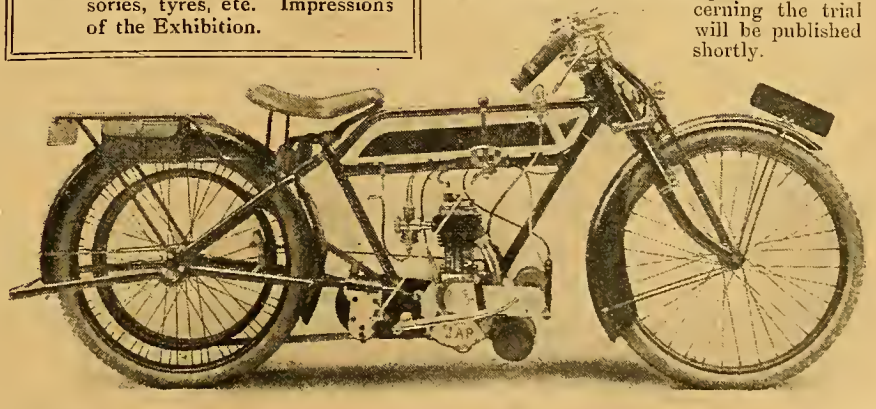
SPECIAL OLYMPIA SHOW NUMBERS.

Nov. 13th.—The feature of this issue will be a comprehensive survey of passenger machines.

Nov. 20th.—This issue will contain a forecast of the Exhibition, particulars of new models, also plan of the Show and list of exhibitors. This number will be on sale at the Show.

Nov. 27th.—Full Show report. This number will also be on sale at the Show.

Dec. 4th.—Review of sidecars, accessories, tyres, etc. Impressions of the Exhibition.



The new 2¾ h.p. Dot-Jap fitted with an Albion two-speed gear and clutch. Chain and belt drive is adopted on this model, the machine being finished in all red. A full description of the new Dot model will be given next week.

THE 1920 AMAC CARBURETTERS.

Simplicity of Construction and Control. One or Two Levers.

AMAC carburetters have been very popular in the past, and deservedly so. This fact, combined with the good reports we have heard of the new single-lever patterns should make a description of the new models more than usually interesting. The principle upon which the carburetters work is the same in each case, though the constructional details vary to some extent. We propose first to describe a model which is likely

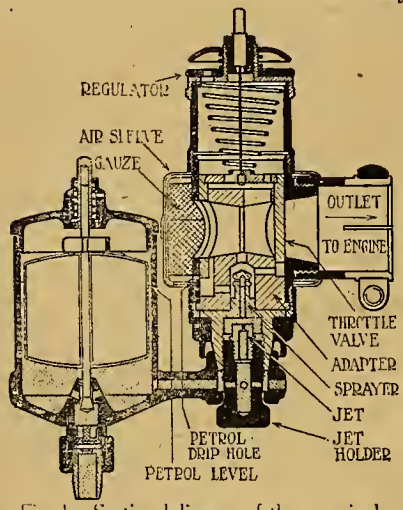


Fig. 1.—Sectional diagram of the new single lever Amac Y carburetter.

to become very popular amongst most cyclists, viz., a single-lever carburetter suitable for horizontal inlet pipes.

The Y Model.

Let us follow the course of the petrol in its passage from the tank to the engine. The float chamber is that already familiar to Amac users, having bottom feed and an inverted needle. From the float chamber the fuel passes through the jet, which in the Amac is distinct from the sprayer, and simply controls the amount of fuel fed to the engine. Above the jet is placed the sprayer, from which the fuel issues in a finely atomised condition through small horizontal holes near the top. Previous to this, it has been in a liquid state, but it now encounters a rapidly moving stream of air, which, traversing through the small passages which surround the sprayer, vaporises the fuel and carries it to the engine.

The throttle has a V-shaped slot, which first uncovers this passage, and provides a small amount of rich mixture, so useful for starting and smooth slow running. The main air orifice is now practically open, but air has access to the engine only through the small passages mentioned. The length of the V slot gives a certain amount of control before the main body of the carburetter begins to open. When this happens the main air is partly cut off by the throttle barrel, which rises across it. This causes the suction on the main vapour hole situated just above the sprayer, and draws up petrol vapour where air had previously been descending into the small passage, and we have a moderately rich mixture for ordinary running. Beyond this point air and throttle open together until at full opening the air is drawn through a venturi tube clear of all obstruction and carburetted on its way both through the main and small vapour passages.

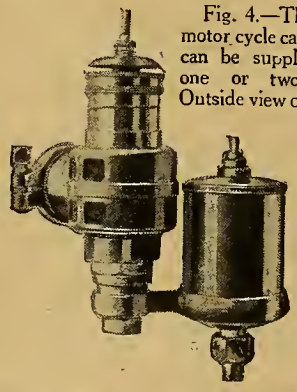

Fig. 4.—The Amac motor cycle carburetter can be supplied with one or two levers. Outside view of fig. 1.

The object of the regulator at the top of the carburetter is to assist in the choice of the most suitable jet, and to give an adjustment for temperature, a single hole being suitable for cold weather and three or more holes when the weather is hot. The positions are numbered 0 to 5. If numbers 2, 3, or 4 give good results the jet can be taken to be correct. Theoretically No. 3 is preferable. If fewer holes are required for good running the jet is too small, and, similarly, more holes suggest too large a jet. Different adapters can be fitted. A larger adapter is suitable for racing purposes, but for normal running it should be as small as is consistent with good results, a suitable jet being fitted. The same carburetter can also be supplied with two levers, the extra air valve then forming an adjustable choke, but the single lever is recommended. These carburetters are known as the Y models.

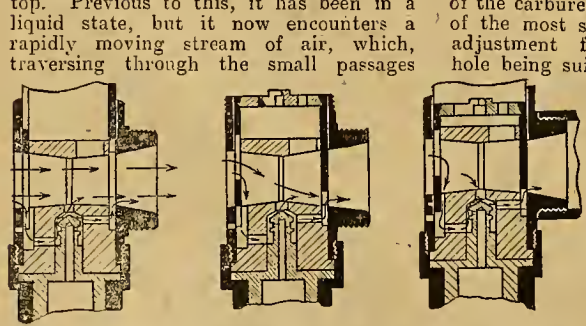

Fig. 2.—Sectional diagrams showing the flow of air and mixture at varying throttle openings. On left, full throttle and uninterrupted passage through venturi tube; in centre, moderate throttle opening, air partly cut off; on right, throttle just open for starting and slow running, air passing through small passages around the sprayers.

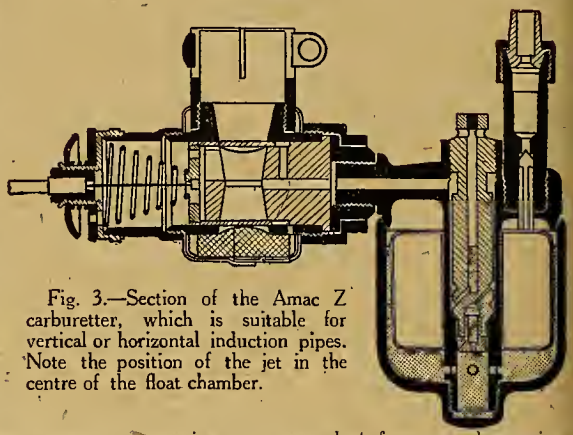

Fig. 3.—Section of the Amac Z carburetter, which is suitable for vertical or horizontal induction pipes. Note the position of the jet in the centre of the float chamber.

The Z Model.

A second pattern is also manufactured, again with one or two levers, and known as the Z model. These are suitable for both horizontal and vertical inlet pipes. In these, the jet holder is situated in the centre of the float chamber, into which petrol passes through a top feed, the flow being controlled by an annular float. The jet holder has a passage down its centre, communicating with the atmosphere, and down this air is drawn by the suction of the engine into an annular groove, when it meets and atomises the petrol passing through the jet. The mixture then passes to the engine through passages similar to, but rather longer than, those contained in the Y models. From this point the action of both models is identical. A distinct advantage of this model is that the jet holder can be removed for the purpose of changing a jet without disturbing the carburetter in any way or spilling a drop of petrol.

The Amac control giving a straight pull on the wires has, naturally, been retained, and this prevents breakage of the wires. The lever can be placed on either side of the handle-bars, and is made to open either way, as the rider may desire.

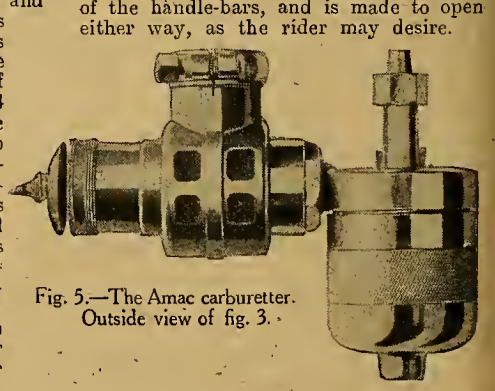

Fig. 5.—The Amac carburetter. Outside view of fig. 3.

AN AUTUMN TRIAL IN WALES.

Liverpool Motor Club's Successful One Day Trial.

A TRIAL in Wales, under the most favourable climatic conditions, is generally a strenuous affair, but a trial in the late autumn, including mountain tracks and through watersplashes, which after heavy rain become deep and swift torrents, is an event to test the durability of the modern motor cycle and the sporting spirit of the most hardened competition rider. Such a trial was successfully run off last Saturday, by the Liverpool M.C., a body enjoying a high reputation as organisers of sporting events.

The 115 Mile Course.

Starting from Birkenhead, the course led to Northop, near which place an acceleration test was held on a slight grade, the competitors being brought to a stop and restarted. They were timed over a stretch of 120 yards by Mr. T. Silver, who is an A.C.U. timekeeper.

The finish of the acceleration test was the commencement of the brake test, competitors being required to pull up in a given distance, in which the performances were consistently good. We rather suspect that this test was included merely to ensure that all the competing machines had brakes adequate for the severe descents they were called upon to traverse later in the day. If such were the case, the idea was good, as without powerful brakes, some of the hills would have been dangerous.

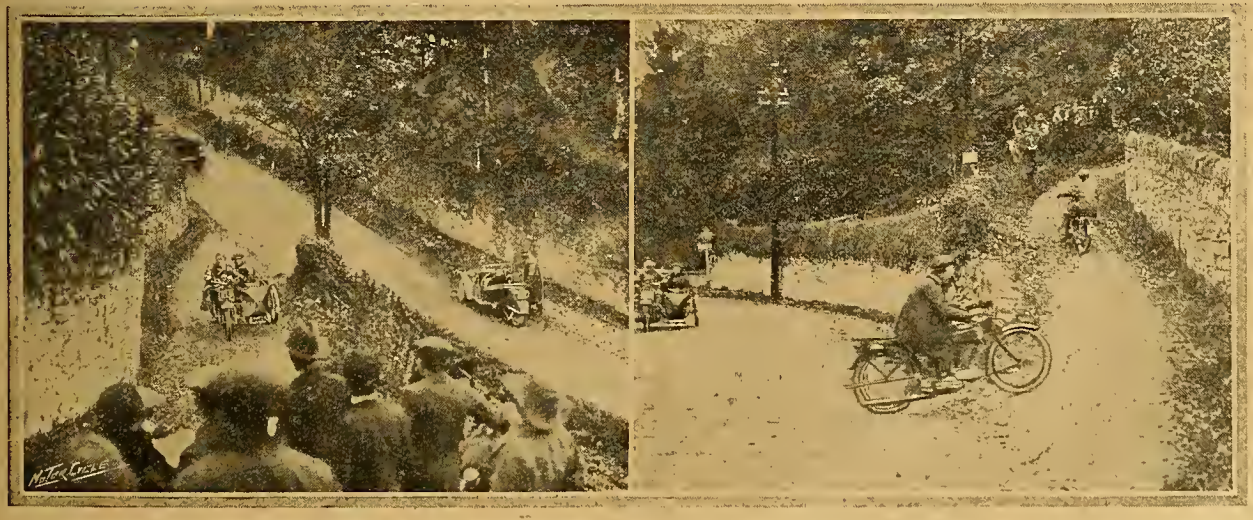
The next ten miles were through narrow lanes ending in a climb into Holywell, out of which town the competitors were taken up Pen-y-Ball, which was in a very rough condition and accounted for quite a number of failures. Then came grass tracks, greasy hills, and deep streams to ford, a trying stretch through Ysciefiog, Nannerch, Cilcain, to the lunch stop at Ruthin.

H. Poole (4 A.J.S.) and N. Svanso (8 Morgan) on Pen-y-Ball.

The fords proved to be deeper than the officials anticipated, for the heavy rains the day before had turned rippling brooks into roaring torrents that came well over the wheel centres. It was an unexpected feature of the trial, and generally the machines performed most creditably. Several competitors stopped in midstream, two machines got entangled, and at least one other fell over and was completely submerged. There were two of these fords, and although most of the competitors got a thorough wetting, on the whole the adventures seemed to be keenly enjoyed. The feature, however, did not discover many weaknesses in magneto design, although the riders of the Brough machines, with their magnetos placed high in the frame, were envied by many who suffered anxiety on this account. One could not expect the chain-cum-belt transmissions to be immune from slip under such conditions.

Probably the descents caused more real anxiety than the ascents, for the slippery state of some of the hills made braking a trying task. Both solo and sidecar machines slithered down crabwise, and on one of the descents Greaves (Morgan), in trying to hold his machine behind two slowly-descending solo riders, skidded right round until he was facing up the hill.

At Ruthin there were many experiences to relate over lunch while the officials examined the seals on the petrol fillers and replenished the tanks, for each man's fuel was measured out to him, a petrol con-



Sun Trevor—the *piece de resistance* of the trial. (Left) Looking down the lower portion of the hill at the hairpin. F. W. Giles (6 A.J.S.) essays the climb. (Right) E. Williams (4 A.J.S.) followed by T. Weaver (2¾ Verus).

J. H. Place (8 Dot sc.) breaks a chain on Sun Trevor. Note the width and the surface of the hill.

sumption test being included in the trial, the results of which should be most interesting when they have been worked out by the committee. This was included to encourage economy in fuel, and it is a pity that it is not made a regular feature of all trials. As an example of what can be done with a sidecar machine, even under the trying conditions of a trial, we may cite V. E. Horsman's 4 h.p. Norton machine, which covered the course on a consumption of 83½ m.p.g.

Sun Trevor Hill.

From Ruthin the course lay over twenty miles of lanes to Llangollen, a mile beyond which town was the *pièce de résistance* of the trial. This was a narrow twisting hill from the Wrexham road to the Horse Shoe Pass, known locally as World's End, but figuring on certain maps as Sun Trevor. The gradient was severe, and there was a sharp right-hand hairpin bend at the steepest part, while the surface was several inches deep in mud. In the latter respect we were reminded of Grindon Hill in the 1914 Six Days Trial, while the scene at the bottom was reminiscent of that at the foot of Litton Slack, for an unarranged control was in operation, and the competitors sent up—mostly pushed up, by the way—one at a time. It was merely a question of road grip—power, at no time, was lacking, and it seemed absurd to include such a hill in a trial. However, in fairness to the organisers, it should be stated that the hill was in an unusually bad state owing to Friday's rain.

Following this hill came ten miles of mountain tracks through farmyards and round several sharp hairpins to Llandegla, whence the competitors had easier going through Hope and Queensferry back to Birkenhead.

The finish was in the dark, and, without doubt, many of the riders made very fast times, as several succeeded in making up the time lost at the foot of Sun Trevor. Kuhn (Levis) was one of these, but it is questionable whether it was necessary, as the officials are bound to take into account the impromptu control, where few riders were caused to lose less than half an hour at official instigation.

Altogether it was a good trial, well arranged and carried through in the sporting spirit which characterises the Liverpool Club, and severe as it was, there were surprisingly few retirements.

The Acceleration Test.

The following are the times of competitors in the 120 yards acceleration test from a standing start. Those marked with an asterisk lost three marks for failing to attain the minimum speed allowed, *i.e.*, 18 m.p.h. solo machines, 12 m.p.h. sidecars.

	Time.
S. W. Phillpott (5 Brough sc.)	11⅕s.
V. E. Horsman (4 Norton sc.)	11⅗s.

T. B. G. Vale (4 Norton)	*12⅘s.
J. H. Green (7-9 Excelsior)	12s.
H. Pattinson (4 Triumph)	12⅘s.
G. E. Kuhn (2½ Levis)	12s.
G. Brough (5 Brough)	11⅘s.
R. Storey (7-9 Excelsior)	11⅘s.
F. Marshall (3½ Sunbeam)	10⅕s.
J. A. Newman (3½ Sunbeam)	*12⅘s.
P. V. Morris (3½ Sunbeam)	*13s.
F. W. Ratcliffe (5 Brough)	*15⅘s.
E. Ladefoged (3½ Sunbeam)	12s.
N. C. Sclater (10 Henderson)	*13⅘s.
—. Eadington (3½ Sunbeam)	*13s.

Observations on Pen-y-Ball.

The following riders made fast ascents: Noel Brown (7-9 Indian), W. B. Gibb (2¾ Douglas), R. Storey (7 Excelsior), J. A. Fox (4¼ B.S.A.), J. H. Green (7 Excelsior), Geo. Brough (5 Brough), R. Charlesworth (5 Zenith), and H. Pattinson (4 Triumph). Of those who climbed steadily we noticed G. Kuhn (Levis), P. V. Morris (3½ Sunbeam), F. W. Ratcliffe (5 Brough), R. R. Bromley (4 Triumph), T. B. G. Vale (4 Norton), H. Poole (4 A.J.S.), E. L. Booton (3½ Sunbeam), T. Highfield (5 Brough), R. R. Coes (7 Indian), L. T. Gibson (4-5 Zenith), M. Davies (3½ Sunbeam), N. C. Sclater (10 Henderson), and —. Eadington (3½ Sunbeam). The sidecars on the whole did well, the few exceptions including R. A. Shacklady (4¼ B.S.A. sc.), who apparently was handicapped by the loss of his arm, J. D. McClean (7-9 Harley-Davidson sc.), J. E. Duffey (6 Humber sc.), and C. R. West (6 A.J.S. sc.), who turned over on the top bend.

Performances on Sun Trevor.

One of the first sidecars to climb Sun Trevor was V. E. Horsman's 4 h.p. Norton, and he made a clean ascent. He

F. W. Irving (4 Triumph) and Geo. Brough (5 Brough) on Pen-y-Ball.

An Autumn Trial in Wales.—

proved to be one of the few exceptions, however, and to mention all passenger machines would be a repetition of words: "Stopped—wheel slip." Several made good restarts after being assisted over the patch of loose earth and mud which brought so many to a standstill with smoking tyres. Among these we noticed W. Edwards (4¼ B.S.A. sc.). F. W. Giles (6 A.J.S. sc.) and H. B. Denley (10 Morgan) both did well, as did the following solo riders: W. Ratcliffe (3½ Brough), B. Kershaw (2¾ Verus), Geo. Wray (3½ Triumph), H Pattinson (4 Triumph), Geo. Brough (5 Brough), T. W. Ratcliffe (5 Brough), J. W. Wills (10 Henderson), S. Parker (10 Henderson), J A. Newman (3½ Sunbeam), and E. Ladefoged (3½ Sunbeam). The steadiest ascents were made by E. J. Boston and F. Marshall (3½ Sunbeam), while the fast and clean climbs by G. Kuhn (2½ Levis), R. Storey (7 Excelsior), and J. H. Green (7 Excelsior) were bordering upon the sensational.

Final Examination.

We discussed the question of cleanliness with F. A. P. Zacharias, the judge, who examined each machine for condition, and he told us that on the whole the machines showed little trace of the hard day's gruelling, and noticed specially the absence of oil about the majority of engines. The Brough machines particularly were mentioned by him, and on examining the crank cases of these flat twin engines we found no trace of oil at any point.

The American Excelsior and Henderson machines were brand new, and had only been taken out of their crates the day before, and on this account the riders had perhaps been over liberal with oil.

Of the eighty entrants, seventy-one started, of which number sixty-one finished. C. R. West (6 A.J.S. sc.) and R. A. Shacklady (4¼ B.S.A. sc.) turned over, L. Reynolds (5 Brough) fell after collision with a dog, and one or two found the course too severe for their machines.

The official results had not been worked out at the time of going to press, but probably they will be announced in next week's issue of *The Motor Cycle*.

CLUB NEWS.

Future Events.

Oct. 31.—Meeting of Birmingham Club Officials to discuss Question of Amalgamation, Chamber of Commerce, Birmingham.
NOV. 1.—SOUTH BIRMINGHAM M.C.C. OPEN TRIAL FOR PALMER CUP.
Nov. 2.—Reading and District M.C. and L.C.C. Run to Crookham Common.
Nov. 1.—Edinburgh and District M.C. Trial for Amateurs for Palmer Trophy.
Nov. 8.—Birmingham M.C.C. Closing Run.
Nov. 8.—South Birmingham M.C.C. Trial for Sangster Cup.
Nov. 9.—Reading and District M.C. and L.C.C. Run to Wallingford.
Nov. 13.—N.M.C.F.U., Leeds. Annual General Meeting.
Nov. 21.—N.M.C.F.U., Leeds. Whist Drive and Dance.
Nov. 29.—N.M.C.F.U., Coventry. Run to Olympia Show.

Redditch and District M.C.C.

The closing competition of the Redditch and District M.C.C. took the form of a fast hill climb, and attracted a considerable amount of interest, the competition in the Expert classes being particularly keen.

Three classes were run off with the following results (A.C.U. formula):

EXPERT SOLO CLASS.

1.	F. Bicknell (2¼ Enfield)	36.2
2.	S. Bright (2¼ Enfield)	37
3.	H. Hanks (2¾ Enfield)	39.4

EXPERT SIDECAR CLASS.

1	F. W. Viles (4¼ B.S.A.)	35
2.	D. Guise (8 Enfield)	60.4
3.	H. Spencer (8 Enfield)	80.5

GENERAL SIDECAR CLASS.

1.	H. Garner (4¼ B.S.A.)	51.5
2.	J. Sheppard (6 Enfield)	68
3.	H. Herbert (4¼ B.S.A.)	78.2

The prize for fastest time was taken by D. Guise (8 Enfield solo), 35⅕s. The fastest ascent in the sidecar class was made by F. W. Viles (4¼ B.S.A.), whose time was 44s. The formula used accounts for the disparity of results. Small engines easily win.

On Friday evening last the Redditch Club held the annual dinner at the Unicorn Hotel, Redditch. The club, like so many other similar institutions, had to suspend its activities during the war, but it has had a remarkably spirited and successful revival, its strength increased by its period of quiescence, and now shows the promise of doing a lot of useful work. It is one of the most strongly established clubs in the Midlands, the members and officials evincing a keenness of interest in affairs which makes for further progress. The competitions promoted during the season have been well arranged and conducted. At the dinner there were several present who are prominently connected with the sport and the trade, and the whole proceedings were of a most enjoyable character.

Loughborough M.C.C.

As the outcome of a meeting held at the Bull's Head Hotel, Loughborough, last week, a local motor cycle club, affiliated to the A.C.U., was formed.

A temporary committee was elected as follows: President, Mr. R. S. Clifford, jun.; hon. secretary, Mr. K. S. Topping (8 h.p. Sunbeam); committee, Messrs. N. Dowland (8 h.p. Royal Enfield), Ashcroft (3½ h.p. Rudge), Caldwell (4 h.p. Campion), Chambers (4¼ h.p. B.S.A.), Pash (6 Rex), and Amey (3½ Brough twin).

It was decided to fix an annual inclusive subscription of 12s. 6d. For the first run of the season, it was intended to join the members of the Ilkeston club in their outing to Crick. The Ilkeston club, however, wired to the effect that it had cancelled its run, and the Loughborough members accordingly made the excursion on their own. The weather was ideal, and a very enjoyable day was spent. The features of the afternoon were the climbing powers of Dowland's 8 h.p. Enfield combination and "a certain liveliness" about Byles's 4 h.p. Hazlewood-Jap twin. A slipping clutch, which was soon rectified, was the only trouble experienced.

Essex M.C.

The committee have pleasure in announcing that they have arranged with Mr. Douglas Leechman, barrister-at-law, and the well-known authority on motors, to lecture at the Royal Automobile Club (Associates' Room) upon the 1919 Olympia Motor Cycle Show. The provisional date will be Thursday, December 4th, but definite notice will be issued later.

All motor cyclists, whether members of the club or not, will be heartily welcomed, and as so many novelties will doubtless be shown, a very interesting evening will be spent.

In pre-war years the Essex Club always organised a similar meeting, when motor cyclists had the opportunity of hearing various points discussed by many of the best known riders in the trade.

Novices will doubtless get many hints, which will help them to decide what machine to buy for 1920.

Edinburgh and District M.C.

It will be remembered that this club was to hold a trial on October 4th for the trophy presented by the Palmer Tyre, Ltd., and that the event had to be postponed on account of the railway strike. It has now been decided to hold the competition, which, by the way, is confined to genuine amateurs, on Saturday next, November 1st. The start is from Liberton car terminus, and the route is pretty much the same as that of the Sporting Half-day Trial, held in June, but, in addition, Lammerlaw Hill is to be included, and in the opinion of some who have tried it, this hill is just about as bad as some of the Six Days ones. The surface is terrible, consisting of ruts, boulders, heather, and grass, and the gradient is about 1 in 7. The hill is two miles long, and those who are lucky enough to get up, non-stop, hold a good chance of winning the twenty guinea prize. The Trials secretary is Mr. J. Watt Anderson, 6, Castle Terrace, Edinburgh. Entries close to-day, October 30th.

Bath and West of England M.C.

The competition by members of the Bath and West of England Motor Cycle Club for the Latimer Cup attracted twenty-two competitors, of whom the following is a list:

C. B. Newman (8 Zenith sc.)
A. Worsfold (2¾ Douglas)
W. W. Moore (4 Douglas sc.)
F. G. Ball (2¾ Douglas)

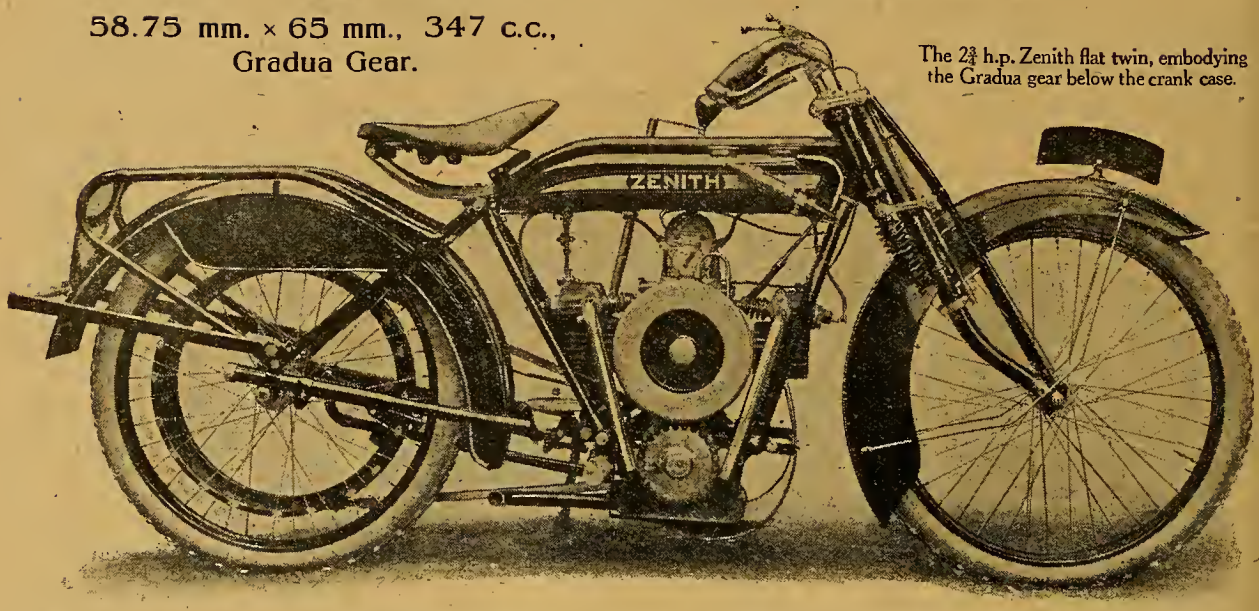
A. S. Moon (3½ B.S.A.)
F. Tuplin (3½ Triumph)

The route taken covered an approximate distance of forty miles over some of the roughest country and hills in the district. The results have yet to be announced by the committee. It will be noticed that out of the twenty-two machines in the competition, thirteen were from the Douglas firm, three were Nortons, and one each Zenith, Harley-Davidson, Sunbeam, Blackburne, Triumph, and B.S.A.

A 2¾ h.p. FLAT TWIN ZENITH.

58.75 mm. × 65 mm., 347 c.c., Gradua Gear.



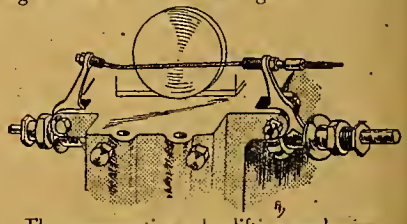
The 2¾ h.p. Zenith flat twin, embodying the Gradua gear below the crank case.

WE have known for a long time that Zenith Motors, Ltd., had a 2¾ h.p. flat twin on the stocks, and as early as May this year we had a short run on this attractive little solo mount, which behaved admirably. A study of its general arrangement reveals the fact that its designer, Mr. F. W. Barnes, has evolved an ideal motor bicycle of medium weight for the motor cyclist—young, middle-aged, or old—who needs a machine which is lively, comfortable, and flexible. As regards simplicity and efficacy, the Gradua gear is unassailable, and it is not surprising that it is adopted in this entirely new model. The manner in which the main Zenith features are retained, while the machine is adapted to accommodate the new horizontal opposed twin-cylinder engine, is extremely neat and ingenious. The new engine is remarkably well finished and of distinctly pleasing appearance, and follows standard practice throughout.

A Neat Power Unit.

The cylinders are clean castings, having the valves at an inclination so as to improve the design of the combustion space and to allow free circulation of air round the valve ports and between them and the cylinder. The tappets are of large dimensions, and have large heads which come in direct contact with the cams, which are solid with the camshaft, and are designed so as to give a rapid lift and closure of the valves and yet to allow the latter to work silently. Both the crank and camshafts run on Skefko self-aligning ball bearings. The engine is as well-finished internally as externally; all important parts, such as crankshaft journals, are hardened and ground, and the connecting rods, which are provided with split big ends, are machined all over. Lubrication is by splash, an ordinary hand pump being used. The oil pipe is connected to a union on the crank case, and the lubricant, after entering this, is directed into two channels, one leading into the crank case and the other into the front cylinder, a hole being drilled in the base of the latter which registers with the channel referred to above. This system secures an equal supply of oil to both cylinders.

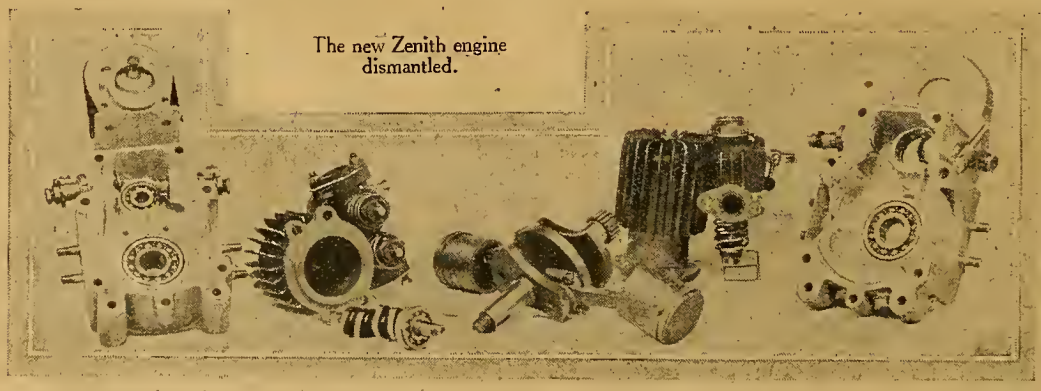
The frame of the new model is well worthy of comment, as the usual down tube and saddle tube are in duplicate so as to leave room for the cylinder heads. The engine is bolted to a cradle which rests on a short tubular frame member; beneath it is an aluminium casting holding the Skefko ball bearings in which the chain-driven countershaft runs, while below this is the rectangular silencer, out of which leads a short exit pipe.



The compensating valve-lifting mechanism on the Zenith flat twin

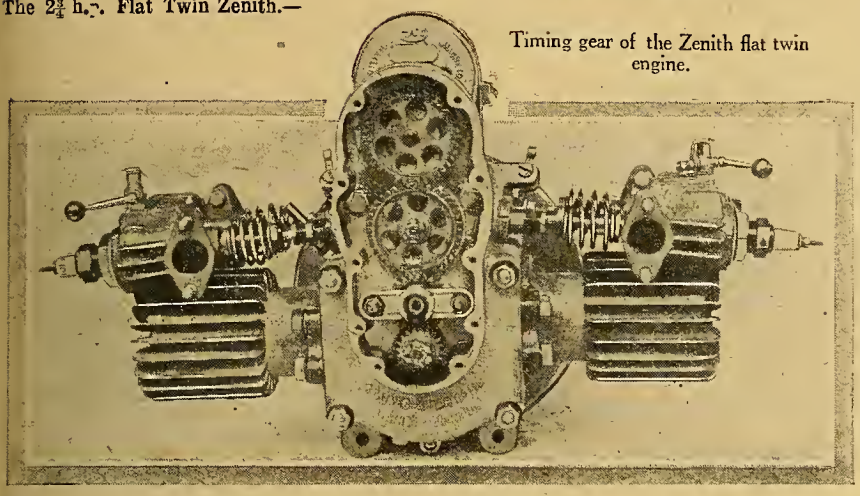
Novel Brake Operation.

In the general design of the machine it is easy to see that ample provision has been made for accessibility, and the cylinders may be removed without dismounting the engine from the frame. Considerable ingenuity has been displayed in the design of the new belt rim brake, and it is clear that it was no easy matter to actuate a rod controlled brake, which the latest pattern now is (a Bowden wire was used in the earlier Zenith models), on a wheel which is capable of a certain amount of longitudinal movement. This feat, however, has



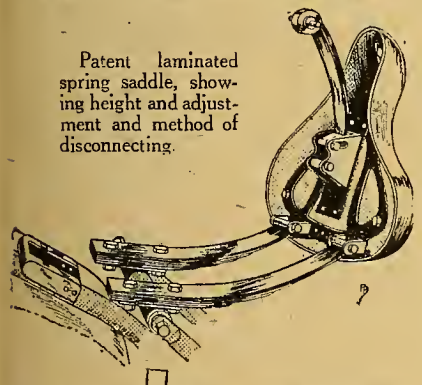
The new Zenith engine dismantled.

The 2¾ h.p. Flat Twin Zenith.—



Timing gear of the Zenith flat twin engine.

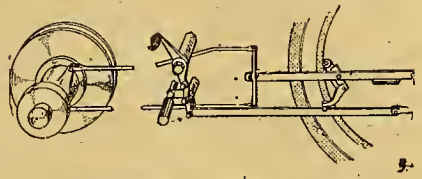
been successfully accomplished. The brake shoe is mounted on a flat rod, the rear end of which is anchored to the back wheel spindle, while the forward end is attached to the expanding pulley mechanism. The brake shoe lever has a slotted end which slides on a flat rod anchored to the rear of the chain stays and actuated by a pedal and toggle mounted on the near side footrest. It is an excellent piece of design, and allows the brake to be worked positively, no matter what the position the rear wheel occupies. We have previously referred to the Zenith patent saddle, which is so effective that it gives equal comfort to that afforded by a spring frame. This, we may remind



Patent laminated spring saddle, showing height and adjustment and method of disconnecting.

our readers, consists in suspending the saddle on laminated quarter-elliptical springs, while the saddle peak is mounted on a similar pattern spring, the forward end of which is provided with a roller working in a specially designed recess attached to the top tube. The forward end of the saddle may be lifted out of its recess and the whole saddle may be tipped backwards, so that in wet weather the actual seat may be kept dry in the event of the driver having to leave the machine standing in the rain. Means of adjustment are also provided to the forward spring so that the tilt of the saddle may be altered to suit the rider's requirements.

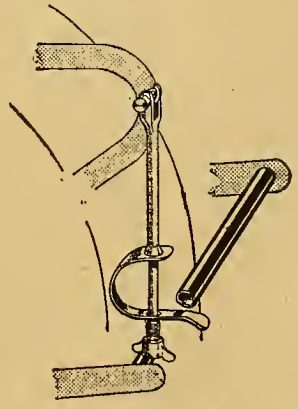
The rear of the frame is of particularly neat design; a spacious and substantial carrier is fitted, and the leverage of the stand is so arranged that the machine may be jacked up with one hand. Instead of being clipped on to the rear of the back mudguard, the stand is secured by a special clip attached to the end of the luggage carrier. Points of convenience have been carefully thought out.



A diagram (not to scale) of the rear brake adjustment.

An efficient shield protects the gear-operating mechanism, while a front guard keeps wet and mud from the transmission. Altogether the new Zenith strikes us as being an exceedingly practical mount, which should be very popular during the coming season amongst those who require a light and fast mount of the sporting variety.

The 4-5 h.p. and 8 h.p. twin-cylinder Zenith-Jap models embody several of the novel features we have just mentioned, but otherwise do not depart to any great extent from standard practice, embodying as they do the well-known J.A.P. engines and the well-tried Gradua infinitely variable gear.



The rear stand clip on the flat twin Zenith.

OLYMPIA NUMBERS OF "THE MOTOR CYCLE."

The issues of *The Motor Cycle* for November 13th, 20th, and 27th, and December 4th will be of more than ordinary interest, as they will deal chiefly with next year's models, both of machines and accessories. The issue for November 13th will be a comprehensive survey of up-to-date passenger machines, with descriptions and numerous illustrations of all the most important sidecar outfits and three-wheeled runabouts. A forecast of the Show will be the chief feature of the issue for the 20th, and on the 27th *The Motor Cycle* will contain a complete and critical description of the motor cycle exhibits. The issue for December 4th will deal fully with accessories and sidecars, and the four issues mentioned will cover the whole field in which motor cyclists are interested.

AVERAGE PRICES.

Second-hand motor cycles are offered a little more numerously than during the past two or three weeks. The prices are well maintained, and the averages worked out from the advertisements which appeared in last week's issue may be truly regarded as fairly indicating the current market values of second-hand mounts of the makes and dates mentioned. There is no doubt that, of all the journals connected with the pastime, *The Motor Cycle* is best able to reflect the state of the market by virtue of its overwhelming number of readers' small advertisements; for example, last week upwards of 900 motor cycles were offered for sale by readers, apart from those listed by the large dealers in their displayed announcements. A tendency to offer machines at more reasonable figures is noticed, the only flagrant cases of "over list-price" occurring with certain American machines, the owners of which, taking advantage of restricted imports, are "making hay while the sun shines."

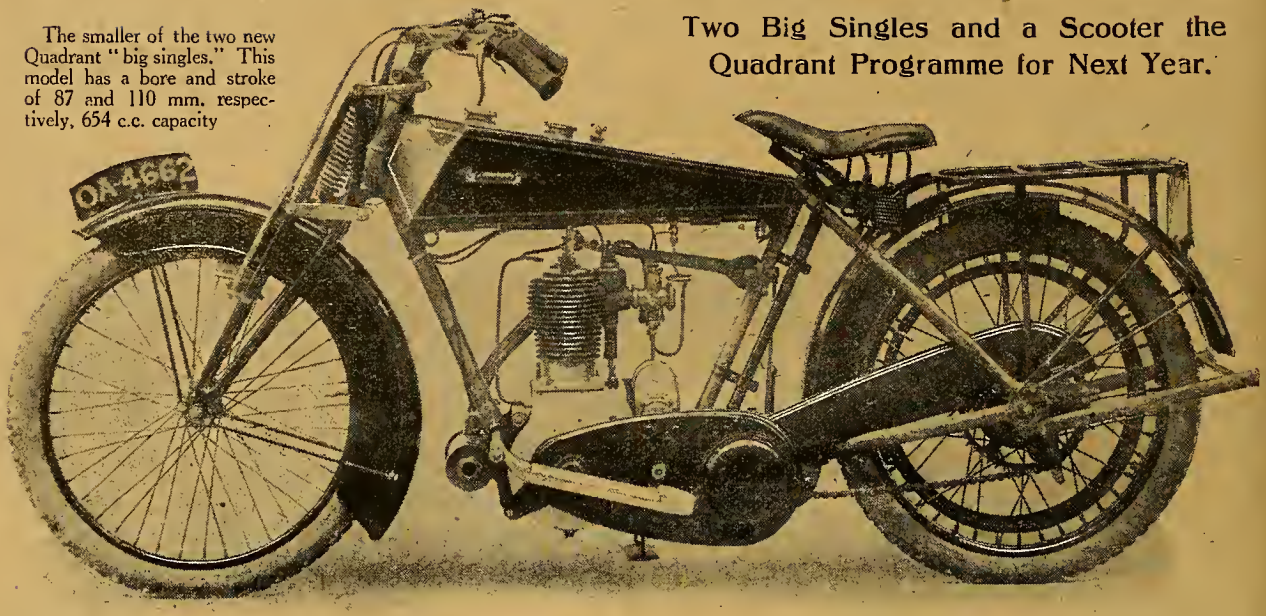
THE 1920 QUADRANTS.

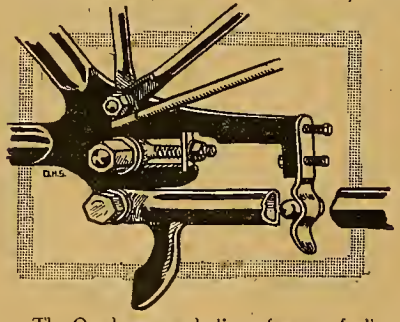
Two Big Singles and a Scooter the Quadrant Programme for Next Year.



The smaller of the two new Quadrant "big singles." This model has a bore and stroke of 87 and 110 mm. respectively, 654 c.c. capacity

THE Quadrant motor cycle requires no introduction to our older readers, who may recall that Quadrant machines were among the pioneer designs. To those who have recently joined the ranks of motor cyclists, or are as yet only potential buyers, the name may not be so well known. With greatly increased production facilities, and with machinery laid down for the manufacture of war material, the Quadrant Co. re-enter the motor cycle industry in a much larger way than before.

Big singles are the chief propositions for next season, for Mr. T. Silver, who



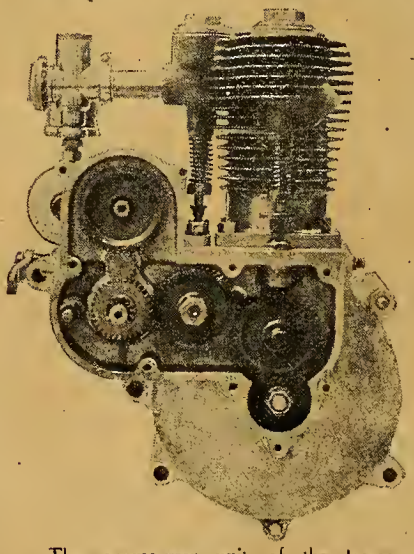
The Quadrant stand clip, a feature of all 1920 models, including the scooter.

has been associated with Quadrants since 1903, firmly believes in the simple and sturdy mount, both for solo and sidecar use.

The first of these models is on more or less conventional lines, having a single-cylinder engine with a bore and stroke of 87 mm. and 110 mm. respectively, the capacity being 654 c.c. It is what may be described as a "hefty" single, but the machine is nicely proportioned, the weight well distributed, and it has a low saddle position, and thus should be easy to handle as a solo machine. For sidecar use the engine will be found quite up to the work as regards power.

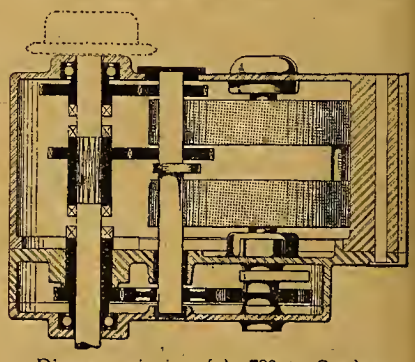
As in the pre-war models, the disposition of the valves of the Quadrant engine departs from conventional practice. Only the exhaust valve pocket is on the side of the cylinder, where it is in the path of an unobstructed draught of air. The valve is operated by a cam driven by a wheel, which forms one of the magneto drive train. An intermediate gear wheel drives a camshaft, which extends across the rear of the crank case. From this the inlet valve, located at the rear of the cylinder, is operated. In most other respects the engine follows accepted practice.

The transmission of this new model is by chains, a Sturmey-Archer gear box being used as the gear unit, and the



The engine-gear unit of the larger Quadrant model, which has a bore and stroke of 95 and 110 mm. = 780 c.c., the largest single now made.

frame is of the straight tube type with diagonal top tube. This latter, however, is not seen when the machine is complete, as the tank is of the saddle type, fitting over the top tube and carried on platforms on the horizontal member. This tank construction makes what to all intents and purposes is a pair of tanks with a common head. This is to say that, excepting when the tank is quite full, the fuel is carried in two separate



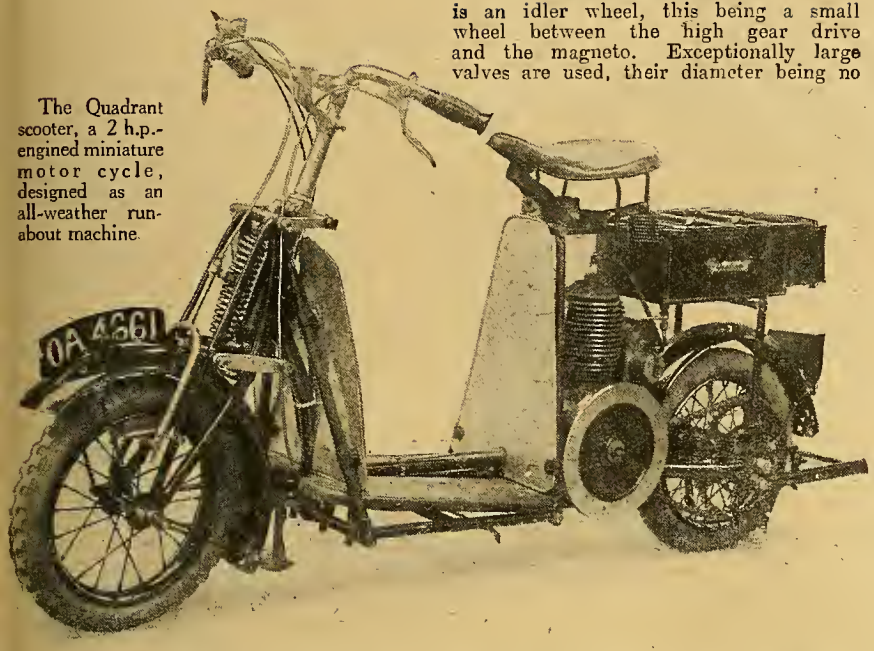
Diagrammatic view of the 780 c.c. Quadrant gear box, which forms a single unit with the engine. Note how the lay shaft is utilised as the camshaft.

compartments—the 2¼ gallons being drawn off by means of a two-way tap.

The stand spring of the Quadrant is novel. Instead of utilising the rear end of the mudguard to carry the spring clip, an extension on one of the fork ends carries a sprung clip which engages a short bar on the stand.

The Larger Model.

A larger engine of 780 c.c. capacity, is used in the second model, which has a bore and stroke of 95 and 110 mm. respectively, and this is built integral with a three-speed gear of the sliding tooth type. The engine portion of the



The Quadrant scooter, a 2 h.p.-engined miniature motor cycle, designed as an all-weather run-about machine.

unit is similar to the smaller model, but the camshaft is enlarged and made to serve as the layshaft of the gear box, and a wheel in the magneto drive train also serves as the primary transmission.

The unit is particularly sturdy in construction, and simplicity is the keynote of its design. Only one gear wheel in the train, from engine-shaft to magneto, is an idler wheel, this being a small wheel between the high gear drive and the magneto. Exceptionally large valves are used, their diameter being no less than 2in., and between the exhaust valve pocket and the cylinder wall there is a clear air passage. The induction pipe is slightly conical, and the exhaust pipe is 1¾in. diameter. The illustrations of this engine gear unit render a lengthy description unnecessary. It will be fitted in a frame similar to that employed in the 654 c.c. model, but in this machine the clutch will be in the rear hub. It has not yet been decided whether the transmission will be by chain or belt, as the unit construction permits the use of a long belt over a large driving pulley, which should remove the objection to the final belt drive of conventional countershaft models.

The third and last Quadrant proposition is a scooter. It has a saddle and a one-gallon tank, and is just as much a miniature motor cycle as it is a scooter.

We understand that a subsidiary company has been formed to market this little machine, and it should take a place in the front rank of such vehicles.

The design is well thought out, embodying a Quadrant spring fork and an open frame, upon which is carried a well-sprung platform. The 2 h.p. two-stroke engine is located below the saddle, and drives directly to the rear wheel by a chain. Over the wheel the frame is built up to form a carrier, in which is carried a tool-bag and a tank holding a gallon of fuel. Two brakes are fitted—a pair of conventional shoe brakes on the front wheel and a block brake acting on the flywheel of the engine.

In addition to front and rear mudguards over the wheels, wide shields are fitted fore and aft of the platform. The wheels are shod with 16 × 2½in. tyres, and the rear stand follows the principle of those fitted on the "big single" models.

It occurred to us that with 22in. or 24in. wheels a machine of this design would meet a very certain potential demand for a miniature motor cycle with a greater range of action than is expected of a scooter.

An Attractive Solo Mount.

A Specially Designed Scott, fitted with Dynamo Lighting, Special Tank and Oversize Tyres.

AN unusually smart mount was ridden in the recent Scott Sporting Trial by R. W. Stanfield.

The model on which he competed is not one available to the general public, having been largely designed to conform to the tastes of its owner. That these tastes show a nice fastidiousness is at once apparent from an examination of the accompanying photograph.

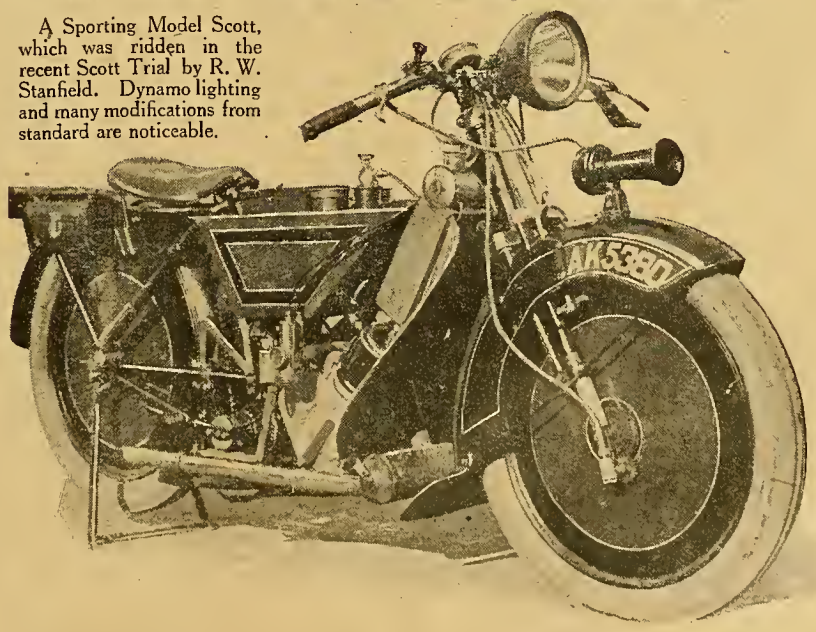
A standard Scott forms the base of the layout, and the chief deviations from the normal specification take the form of alterations to the petrol and oil carrying systems, the adoption of dynamo lighting, and the fitting of T.T. bars of very racy shape, and disc wheels.

The usual petrol tank encircling the saddle tube is discarded, and the whole of the open frame filled with a large, flat-topped and extremely wide tank. This contains an oil compartment, so doing away with the necessity for embodying the filler cap in the seat pillar as is done on the standard models.

By means of this arrangement it is possible to use a Brooks saddle, which "sits" very much lower on to the frame than is normally possible. Switch box, hand-pump, and twin drip feed lubricators are mounted on the tank top, which presents quite an imposing appearance.

Electric lighting is carried out by means of a Lucas dynamo set. This is driven from the magneto chain; the magneto being placed much higher than usual, and the dynamo sprocket arranged to act like a jockey wheel on the chain. An electric horn, fitted on the front guard extension adds finish to the general appearance. A plated exhaust pipe, wide T.T. bars almost level with the head, and wheel discs, are all conducive to the general raciness.

The owner informs us that, despite the weight, which is much greater than that of a standard model, a speed of 55 m.p.h. is possible. The usual Scott purple and black finish is used.



A Sporting Model Scott, which was ridden in the recent Scott Trial by R. W. Stanfield. Dynamo lighting and many modifications from standard are noticeable.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters must be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

BUTT-ENDED TUBES.

Sir,—With reference to "Ixion's" remarks *re* butt-ended tubes, that sooner or later the butts chafed into a leak, I was much troubled with this, but found on applying soft soap to the butts that no appreciable chafing was apparent after considerable usage. E. STEVENS.

THE WAR MOTORS ASSOCIATION.

Sir,—I can thoroughly endorse the letters of "A Satisfied D.R." and "Another D.R.," with regard to the War Motors Association.

My original application in July had been confused with another of the same name, who, strange to say, had served in the same battalion in France, resulting in one or two similar errors there.

A call at their office, however, resulted in a practically new Douglas in three days, for about £25 less than one could have been bought in the market.

This machine is an extremely good one, and several men, who have bought 1919 Douglases in the ordinary way, have said they would prefer mine.

I found both the staff at the office and the officials sent to distribute the machines at the depôt remarkably considerate, and willing to take any amount of trouble to get one exactly what one wanted. C. E. PEPPER, M.B.

THE VALUE OF THE AUTOMOBILE ASSOCIATIONS.

Sir,—Referring to correspondence which has recently appeared in your columns concerning the advantages to be obtained by joining a motoring organisation, please let me quote my experiences. For the past two months I have been writing to firms all over the country to obtain an accessory made by a very well-known house to fit to my new motor cycle. I have also called on agents in each town I have visited, and the reply in all cases has been "Out of stock, and no hope of obtaining for an indefinite period." A week ago, I wrote to the Birmingham office of the A.A. and M.U. asking them to help me. Result, by return of post, and post free, the article I required reached me from them before they had received my cheque for it. I think this speaks for itself, and illustrates a type of benefit accorded to members of which many are not aware.

On a recent journey of ninety miles, I passed eight A.A. road patrols, and on the return journey six; but I only saw one R.A.C. patrol on the double journey. A W 5728.

HARD LUCK IN THE A.C.U. TRIALS.

Sir,—As a competitor in the A.C.U. Six Days Trials, I read with great interest the different kinds of "hard luck," etc., of various makes of machines and drivers. Here is another case: it may interest you.

I am an amateur, having only driven in one trial before, and that was the Liverpool M.C. open trial on Whit-Monday, 1919. I did the course without losing a mark, but was disqualified for not carrying a passenger. I drove a 1918 6 h.p. A.J.S. military model, fitted with a Bustone sidecar. Day after day I arrived back at Llandrindod Wells with a clean sheet until Friday, when about twenty-five miles from Swansea, on the return journey, I took a corner a little too fast, and finished with a buckled sidecar wheel, as the tyre came off and rolled 120 yards down the hill. For a little time I thought I was beaten, but I took the wheel off and straightened it as best I could by putting it in a gate close by, fitted it up again, and started off to make up the time I had lost, exactly one hour. Forty miles away I had a puncture in the back wheel, which delayed me again, and when I arrived at the foot of the "consistent driving test" hill it was pouring with rain, and not a soul in sight. I completed the course, and arrived 31m. late. I lost 21 marks for being late, 20 for not being in the consistent driving again, and 19 for such as condition, etc., and just scraped through with a bronze medal. My machine finished actually better than at the start. My number was 69—last but three. I think that was the reason no one mentioned the incident. The tail end of the competitors was very rarely seen by anyone of importance. C. COLLINS.

MOTOR CYCLE TRANSMISSION.

Sir,—With reference to the article "Overseas Section" in the issue dated September 25th of *The Motor Cycle*, I would like to discuss a few of the statements.

First, then, the writer says that there are three distinct types of transmission, which he then proceeds to enumerate, but leaves out *all belt* drive, which certainly should have a place, as two important makers use it, and sporting and T.T. machines have this type of drive. He then enumerates the disadvantages and advantages of the various types of transmission, including the unit system from the engine-shaft to the countershaft, combined with the belt from the countershaft to the road wheel, which he describes as a favourable type of drive; in fact, he speaks of the cleanness, etc., of the belt drive and its obviating the use of a shock absorber; but again he does not mention *all belt* drive. Surely this drive would include the advantages he speaks of, only more so! I will endeavour to show by tabulating its advantages, incorporated with any type of gradual gear, or without it where unnecessary, *i.e.*, in flat countries where a clutch only would be needed.

Advantages of all belt drive:

(a) No shock absorber necessary. Therefore, one has less complication and better cushioning, less strain, and jerk.

(b) No high speed chain or unit system of pinions or gear box, causing friction and absorbing power.

(c) No chain cases and oil baths. Less damage by grit and dust.

(d) Easy to carry spare belt, and easy to fit.

Surely, therefore, all belt drive is as suitable Overseas as any other.

I do not know whether this long-winded epistle is of any interest, but I should like to see the all chain champions give their opinions. I have no interest in all belt machines beyond being the prospective owner of one in India.

In the event of the Editor not being already in a state of collapse, I would like to continue with a discussion of shaft drive, with which the writer finishes his article.

After summing up by stating that the unit system, plus final belt drive, is the best, he goes on to say, "Shaft drive is, of course, the ideal."

I cannot myself for the moment recall any makers who employ shaft drive, although I believe there are one or two. If this drive is ideal, why is it not in more general use? In my opinion, it is not ideal for motor cycles, although it is undoubtedly ideal for touring cars.

Consider its application. It would require a shaft on either side of the back wheel to make it at all symmetrical, which would cause much friction and make it very clumsy.

Brighton. ALL BELT.

SPARE PARTS.

Sir,—*Re* "quick service." Do you not think your readers will find the following refreshing?

Friday.—Velocette frame broken. Money wire order to Messrs. Veloce, Ltd., Birmingham, for new one.

Saturday.—Arrival, by train, of frame (114 miles).

Sunday.—On the road again.

The above is not an odd case with these people, for they have not once "let me down." I have found they can, and do, "move some." Usual disclaimer.

C. E. H. CALVERT.

Sir,—Requiring a new part for my A.J.S., I sent a wire to Messrs. A. J. Stevens, and, although I have no account with them, I received the part next day.

I might add that they do not appear to be in a hurry for their money as, up to the time of writing, I have not received the bill. Usual disclaimer. J. A. CLARE.

Sir,—Having seen in your paper the experience writers have had when requiring spare parts for their machines, I should be pleased if you would publish my experience.

I am riding a 4 h.p. New Hudson combination, and required a new valve, spring, washer, and cotter. I wrote to an agent and got nothing from him for three weeks, but procured direct from the New Hudson people by return of post.

Also, I had carburetter troubles which I took up direct with the makers of it, and got a very curt letter in reply to my questions and an intimation that they would send me a booklet. I heard no more, however, and after three weeks I wrote direct to the New Hudson and had a new carburetter, controls, etc., sent me per return parcel post.

Then I had slight clutch troubles which I thought it advisable to ask the New Hudson people to put right. One of their representatives was at my house the following day and put this right for me.

I think it is only right that when a firm like the above gives such prompt attention, on three separate occasions, the public should be notified, because if all riders had the same experience as I had we should hear considerably less about American competition and American practice.

I may state that I have no interest or connection with the New Hudson Co., but am just a private rider.

Wellington, Salop. E.3623.

Sir,—I noticed recently a letter from one of your correspondents expressing satisfaction at the very prompt delivery of spare parts he ordered from the Enfield Cycle Co., and I wish to add a word of appreciation of the good service given me by this firm during the war. Out here, in the West Indies, it is pretty hard to get anything like spare parts for any kind of machine, but I must say that the Enfield people were as prompt with filling two or three orders for spares for my 3 h.p. model as one could have wished.

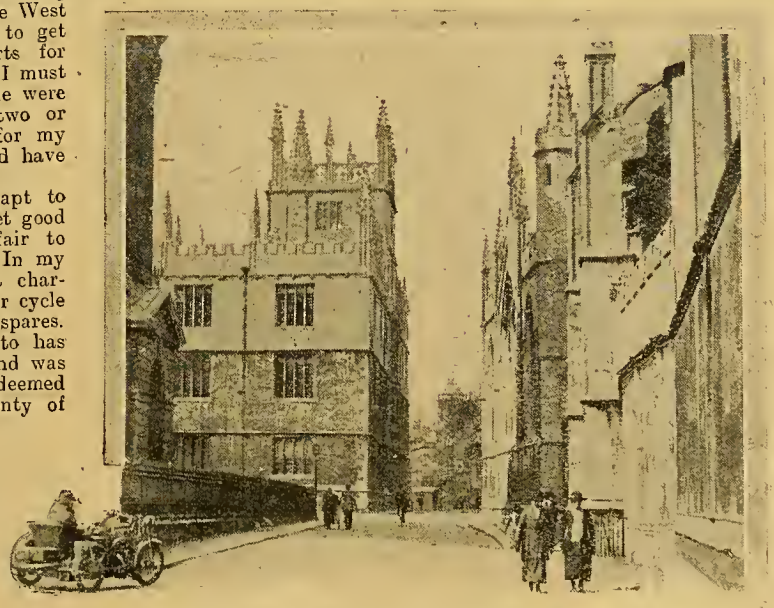
Most of us are very apt to whine when we do not get good service, so it is only fair to speak up when we do. In my opinion, one of the best characteristics of a good motor cycle firm is readiness to supply spares.

The machine referred to has seen very hard service, and was so constantly used that I deemed it advisable to keep plenty of spares on hand, but I may mention that very few have been used, the machine having proved most reliable.

My only relation with the Enfield Cycle Co. is that of a satisfied user.

W. P. EMTAGE.

Barbadoes.



A Matchless outfit in All Souls' Lane, Oxford, the college of that name being on the right. In the middle distance is the famous Bodleian Library.

Sir,—As a reader of *The Motor Cycle*, I quite agree with "Satisfied" that the names of firms who treat their customers well ought to be published. I ride a 4 h.p. Bradbury, and had the misfortune to break my cylinder and piston. Thinking I was in for a long wait, I wrote the Bradbury people to see if they could help me, and you can imagine how pleased I was when they delivered a new cylinder and piston three days after my definite order. I have no connection with this firm only a satisfied rider of one of its machines.

Ilkeston. GRATEFUL.

GEAR CHANGING WITH THE FOOT.

Sir,—I would like to endorse "Sgt. L.A.M.B.'s" letter *re* gear changing with the foot. There is no wobble, and the bicycle can be driven without taking one's hands off the handle-bars, except, of course, to work the oil pump. This applies more particularly to the Triumph 4 h.p., and all bicycles fitted with the Sturmey-Archer countershaft gear and hand clutch. To use the gear in this manner, the gear lever must be adjusted until the ball of the lever, when the gear is in low, is just over the rider's toe. The ball and about two inches of the lever must now be bent to form a right angle with the rest of the lever. If so adjusted it is very easy to work. As "Sgt. L.A.M.B." says, it wants getting used to, but when that is over one appreciates the difference at once. This method of gear changing was very popular among the D.R.'s in France (with whom I believe it originated), when one wanted to hang on with as many hands as possible on the rotten roads.

One word about the Triumph in general. It is a marvellous bicycle, and stood up to the work in France rippingly. I rode my bicycle for two weeks on one occasion, and averaged eight hours riding per day, and gave no attention to it whatever. I did not have any mishap, and it was going as well as ever at the end of it, despite the fact that the engine was unrecognisable with caked mud. A truly wonderful bicycle, I think. Usual disclaimer.

O. F. CAUNTER, Lt., R.E., Sigs.

PATENTS.

Sir,—With reference to the "Review of Recent Patents," in your issue of October 9th, and under the heading "To Eliminate Valve Springs," Mr. B. H. Davies makes a statement that is somewhat misleading.

Mr. Davies refers to the Beardmore engine as "a power unit with pull and push tappets which both open and close the valves positively." This makes it appear that the valve operation of the Beardmore is similar to that described in the patent under review. As a matter of fact, in the Beardmore, as also in the Le Rhône and R.A.F.3a, the pull and push rods are used only for *opening* the valves, one rod for two valves, which are *closed* in the usual manner, *i.e.*, by spiral springs, assisted, in the case of the Le Rhône, by centrifugal action.

In Capt. Burt's patent one pull and push rod is used for each valve, which carries with it the great advantage that a valve overlap can be used, which is impossible in the Beardmore engine.

I fail to see that there is any "side-stepping of previous applications" in this patent, as the object in view seems quite different from that of any existing "pull and push" system.

P. BANHAM.

BUTSER HILL.

Sir,—Referring to B. S. Nortsunbeam's letter on Butser Hill, I think the explanation is fairly simple. I have had exactly his experience.

There is a long deep road cutting through Butser, running about S.S.W., and the prevailing wind blows through this with tremendous force, and its energy is felt a considerable distance down the hill from the mouth of the cutting.

If your correspondent will ride from Castleton towards the entrance of the Winnats Pass in the High Peak when a S.W. breeze is blowing he will experience the same result.

L. R. INCLEDON.

Sir,—I was interested to see a letter in your columns from "B.S. Nortsunbeam" *re* Butser Hill. I am very familiar with this hill, and, as I ascend it frequently, I usually consider it the most reliable test for the running of my machine. This is certainly quite a stiff hill, but if your correspondent's *nom de plume* indicates the makes of machines he has been riding, I am rather surprised that his speed should have been so low (20-25 m.p.h.).

My present 3½ h.p. single, and two twins before it, have all romped up this hill at really high speed, provided I have not lost speed on the bend at the foot—but I well remember the painful struggles of a 1911 3½ h.p. I had some years back.

The hill mentioned about a mile or so after Butser is not so steep—and I usually reckon that I can ascend it 10 m.p.h. faster than Butser. To sum up, I consider that Butser is steeper than it looks (probably because it is in a cutting), and the next hill is not so steep as it looks!

Southsea. O. T. SNORTON.

A COMMENT.

Sir,—Usually I enjoy "Ixion's" comments, but in your issue of October 9th I feel as if I cannot let him go without a comment myself. Anyone would think it was only English machines that shed nuts, etc. My experience is that the American machines do the same, and I have been connected with motors since the days of tube ignition, and ridden almost every known make of motor cycle. He says what *we* want is a manufacturer who will sell machines from which nothing can conceivably come off. But we have these manufacturers, and have had for some years. What rider of a Triumph or Sunbeam, for instance, has ever lost a nut from his mount, provided he looked over the machine when taking delivery? What I mean to convey is that, provided a nut is tightened correctly to begin with, using an ordinary washer, it will never get loose, unless undone with a spanner. I have ridden in several countries, and that has always been my experience. To use split pins on almost every nut on a motor, where gadgets have to be taken asunder very frequently, would only add a long list for Hades. Now a word about kick-starters. What is wrong with the Sturmey, A.J.S., Sunbeam, etc.? The trouble is that people do not drop the valve at the right moment. HENRY EVANS.

JET SIZES.

Sir,—In reply to "C.T.'s" letter in last week's issue of *The Motor Cycle* I trust the following will be of use to him. I have a 4 h.p. military model Sunbeam, which I ran for some time fitted with No. 32 jet (Amac carburetter), and only averaged abont 60 m.p.g. with sidecar attached. This gave ample power for hills, but was unsatisfactory as far as consumption was concerned.

I fitted a W.S.R. jet adapter. Since then matters have improved greatly, and I can now average 84 m.p.g. solo and 75 m.p.g. with sidecar, which I think very good for Surrey.

I find the jet unscrewed half a turn for sidecar work and one-third for solo gives best results; but should imagine no hard and fast rules could be laid down for adjustment, not even on machines of the same make.

I should also be grateful if any possessors of the Sunbeam chain-cum-belt model could give me their experiences of this machine, as I have never seen the machine mentioned in other than sales advertisements. I find it as reliable and handy as any machine I have ever owned, but find great difficulty in starting either hot or cold with the starter. I can walk it off in low gear, which seems to point to the carburetter, magneto, etc., being all in order; but start with the starter I cannot, and am of the opinion that it is geared too low, as I find it impossible to swing the engine over the compression after dropping the exhaust. B.J.

Guildford.

THE MOTOR CAR ACTS, 1896-1903.

Sir,—I think it is high time combined efforts were made, alike by petition to local M.P.'s and by motor journals and press generally, and by all motorists, against the above Acts, which are silly and obsolete. As things stand at present, motor cyclists in particular are subjected to police interference and fines which savour of Prussianism. The fine limits of law contained in these obsolete Acts are used to conjure up summonses and charges, and heavy fines are imposed on the slightest pretext. It seems, by a casual glance at the papers, and the number of motor cyclist cases daily coming before magistrates, that the police have so little to do that they must use the Motor Car Acts to get a case or two to justify their existence. In this locality (South Wales) motor cyclists are watched in all ways, and on the slightest pretext are summoned and heavily fined.

Concerted action is the only remedy, as by the way things are carried out now under the obsolete Acts motor cycling is being made a curse, a source of revenue to the police, and expense to devotees, no matter whether careful riders or otherwise; no one escapes for more than a month or so (in this locality, at least).

I should be glad to have the views of your readers and suggestions on this matter, through the medium of your paper, and any scheme for the repeal of these Acts would have my hearty support in practical form.

H. REG. JONES.

MOTOR CYCLING IN ASSAM.

Sir,—Knowing Assam well, and having motor cycled over most of the roads in the Province, I give the following information for the benefit of Mr. Burd (*vide* your issue of October 16th). His queries are dealt with *seriatim*.

(1 and 2.) There is only one really good road in the whole Province, viz., the road between Gauhati and Shillong, the headquarters of the Local Government and the summer hill resort of the Province. There is a daily mail and passenger motor service over this road, and its condition is usually excellent. The distance between the places named is about sixty miles, and there is a rise of about 6,000 feet in this distance. Apart from this one the Province is almost destitute of good roads. Such roads as there are are mostly unmetalled, and very bad indeed after the rains. For this reason a well-tried machine is essential, and I should certainly prefer the single to the twin, simply because the manufacturers, through their war experience, have been able to produce a machine which will stand up on the worst roads. A large number of Triumphs are sold in India, and, consequently, spare parts are readily obtainable. This might not be the case with a new make of motor cycle. The combined drive of the Triumph is perfectly satisfactory, and I personally prefer this drive to the "all chain." The roads are so very dusty that, however well the chain is protected, dust gets in and causes rapid wear of chain and sprockets, and it is often difficult to get a new chain of correct size. The short chain from engine to countershaft is more easily protected.

(3.) All the leading insurance concerns have agents in India, and it would be better to insure locally.

(4.) The machine must be re-registered in India.

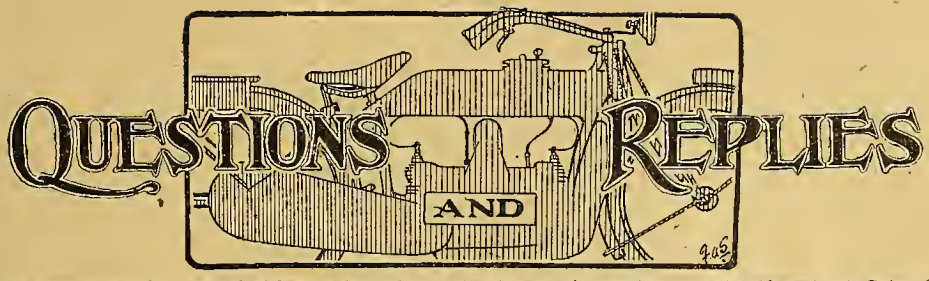
W. D. MACGREGOR.

BOOKS AND MAPS FOR MOTOR CYCLISTS.

Issued in conjunction with "*The Motor Cycle*."

	Price net.	By post.
"MOTOR CYCLES AND HOW TO MANAGE THEM." The standard handbook on the motor cycle—its care and management. Twentieth Edition. 286 pages. 400 illustrations ...	2/6	2/10
"HINTS AND TIPS FOR MOTOR CYCLISTS." Containing over 400 useful "wrinkles" and helpful hints in regard to motor cycles. Sixth Edition. (Second Reprint.)	2/-	2/3
"TRACING MOTOR CYCLE TROUBLES." A reliable system for tracing motor cycle faults and of remedying any trouble when found. Fourth Edition	2/-	2/3
"THE MOTOR CYCLE" ROAD MAPS. **England and Wales. Scotland. London** (showing roads into and out of London and avoiding London). Mounted on linen. Set of three, complete in case	4/6	4/10

Obtainable by post (remittance with order) from ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4, or of leading Booksellers and Railway Bookstalls.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Ex-soldiers and W.D. Sales.

A friend of mine who has recently been demobilised is desirous of buying a strong motor cycle and sidecar combination, and he wishes to know whether the surplus army machines are sold at a reduced price to ex-army men.—E.L.D.

There are no special facilities in the matter of reductions of price to ex-army men in the Government sales of motor cycles.

Blacking Cylinders.

I should be greatly obliged if you could give me the address of any firm who manufactures or sells a composition of any sort for applying to the radiating fins of motor cycle cylinders. My 1919 machine is spotless, except for some rust which has collected on the radiating fins, and I find ordinary blacklead useless.—R.N.B.

It is very difficult to find any preparation which will remain on the cylinder of a motor cycle engine, in order to prevent rust. Most of the accessory dealers will supply you with a cylinder black or radiator enamel, which you can use for the purpose, but the combined effect of weather and the heat of the engine necessitates frequent applications.

No Spark.

I have just purchased and fitted a brand new magneto. After following the instructions given in "Hints and Tips for Motor Cyclists" as regards timing, I find on pulling the back wheel round that there is not the slightest current with a finger on the plug terminals, and yet with the chain removed and turning the sprocket by hand there is a fat spark between the plug points. I should be obliged if you could tell me the cause of this failure to get a spark and the remedy for it.—J.M.

The reason you do not feel a shock from the high-tension wire when revolving the magneto by turning the back wheel is probably due to there being a defective earth return between yourself and the machine. This would be accounted for by the fact that you were only holding the tyre and not any metallic parts of the wheel. The best plan is to take out one of the sparking plugs and lay it on top of the cylinder in such a way that the terminal and wire are clear of all other parts. On pulling the back wheel smartly you should be able to see a spark passing across the plug points.

Touring in France.

May I enquire as to certain particulars with regard to motoring in France? (1.) What is the price of petrol (or motor spirit), and in what size tin is it usually sold? (2.) What oil corresponds to Vacuum "B.B." oil, or can Vacuum be obtained easily? (3.) What is the price of oil?—W.B.S.

With regard to motoring in France, we would strongly advise you to become a member of the Auto Cycle Union, 83, Pall Mall, London, S.W.1., and to get in touch with the Continental Touring Department. (1.) The price of motor spirit in France varies considerably with the district. It is usually from 5 fr. 50 c. to 9 fr. per bidon of five litres (a litre equals one and threequarter pints). (2 and 3.) The oil most in demand for motor cycles is known as Huile D. It is obtainable anywhere, and at prices corresponding with oil in England.

Gear Ratios.

(1.) My machine is a 1915 5 h.p Indian. The gears originally fitted were 4 to 1, 6 to 1, and 10 to 1. As this machine was often fitted to a sidecar, I found the top gear too high, so took off the engine sprocket (eighteen teeth) and fitted one of fourteen teeth, which brings the top gear about 5.25 to 1. Do you not consider this too low? (2.) Would not a sixteen-tooth engine sprocket be better? (3.) What top gear would you recommend for a 1913-1914 4¼ h.p. James, occasionally used solo, but nearly always with sidecar?—S.G.

(1.) A 5¼ to 1 gear is rather low for a 5 h.p. machine. (2.) A sixteen-tooth sprocket will no doubt be an improvement. (3.) 4⅞ or 5 to 1.

Mr. S. A. Rowlandson, late captain R.A.S.C., who is now in Canada as manager of an association of British motor cycle goods manufacturers which has been formed to foster Overseas trade.

Weakness of Retarded Spark.

When retarding a magneto, at what rate, or how much, does the spark decrease in efficiency? Supposing a magneto fully advanced to represent a hundred per cent., what percentage of that spark occurs when the magneto is fully retarded?—H.F.

We cannot state definitely the percentage decrease in efficiency of the magneto when retarded, as it varies considerably with the speed at which the engine is running. In practice there is certainly a weakness of the spark, so much so as to render starting either extremely difficult or even impossible.

The V Twin Magneto.

Will you kindly explain the following questions, dealing with a Splitdorf magneto, fitted to a 7-9 h.p. Indian? (1.) Why is one pole piece larger than the other? (2.) Is it owing to the fact that, as the cams in the breaker box are not set equidistant, the points would start opening either before or after the position of maximum intensity had been reached? (3.) What is the theory of so setting the cranks as to necessitate the use of this type of magneto?—E.A.

(1 and 2.) Your first query is correctly answered by your second. (3.) The V-type engine is largely used as being the most convenient method of accommodating two cylinders in a motor cycle frame, and both pistons are connected to the same crank.

Fitting a Gear.

My machine is a twin Rex, which I have lately rebuilt. It is fitted with a two-speed N.S.U. gear, which has given out, and I want a gear with either handle or kick start. A gear box would not do, as there is no place to fit it without shifting the magneto, which is at the back of the cylinders, and there is very little ground clearance. Perhaps you can suggest something which would be more suitable.—A.D.

As it appears impossible to fit a countershaft gear to your machine, we would suggest that you endeavour to obtain a second-hand Sturmey-Archer three-speed hub wheel. This could be fitted with slight alterations to the rear forks. The N.S.U. gear is usually quite reliable, and if yours is not seriously damaged, we should advise you to have it repaired. Bradbury and Co., Wellington Works, Oldham, will supply spares for these gears.

Moto-Reve Queries.

I am having great difficulty with my 2½ h.p. twin Moto-Reve. I cannot get it timed correctly, as the spark always appears too much advanced on one cylinder. The timing wheels are eccentric. The carburetter is very difficult to adjust, and I am thinking of altering it to take standard jets. What do you advise?—R.E.

The only thing you can do in timing your Moto-Reve is to see that the spark occurs about $\frac{3}{16}$in. from the top of the compression stroke on both cylinders. The eccentric timing wheels were peculiar to these engines. The carburetter first fitted as standard, was far from satisfactory, and we should recommend you to obtain a new one of English manufacture, rather than experiment with, and make alterations to, the old one.

Responsibility for Borrowed Machine.

I recently hired a motor cycle for a small sum for the purpose of going a short journey. On the previous day the owner of the machine had done a long run, and the fact that I myself taught him to ride a motor cycle only six days before shows that he was far from an experienced rider. On going to the garage I did not trouble to look at the machine very much. It ran very well indeed, and on returning it to the garage I notified the manager that I had done so. I heard nothing until a later date, when the owner informed me that the cylinder and crank case were cracked. I cannot say whether the machine has been out since I returned it. Do you think the owner of the machine can claim damages from me?—W.E.H.

Under the circumstances, the owner of the machine cannot hold you responsible for the defect which has subsequently developed.

Two-stroke Queries.

(1.) What is the angle of the 1910 twin Royal Enfield cylinders? (2.) What is the best gear to fit to a 2½ h.p. two-stroke New Ryder lady's model? (3.) Would a Douglas gear do, and would it be hard to fit, as there seems to be plenty of room in the bottom bracket? (4.) How would you time a two-stroke for speed, and will it interfere with its pulling power? (5.) Which is the best size of jet to use for a Villiers engine, as I have a 28in., and as soon as it reaches a good speed it starts spitting, and then pulls up? (6.) Would a Villiers engine pull a light sidecar with driver 10½ st. and passenger 9 st. if fitted with a two or three-speed gear and clutch?—U 1463.

(1.) The cylinders of the 1910 Royal Enfield are set at 60°. (2 and 3.) A Douglas gear box would probably do for your machine, also the Albion or Burman gear boxes are very good. (4.) Time the spark to occur 3 mm. before the piston reaches the top dead centre, with ignition control fully retarded. (5.) The 28 jet should be quite large enough on a Villiers engine. When the symptoms which you describe occur, try closing the air lever. (6.) The engine is capable of pulling a sidecar and passenger if suitably geared.

Cornering at Speed.

Does a motor cyclist usually lean over to the left when going round a corner to his right, as I have found that leaning over on the opposite side keeps the machine steadier and makes the corner easier to get round? Will you please tell me if this is so with expert racers?—D.M.B.

In taking a corner at speed it is quite usual for the rider to lean in the opposite direction. This enables one to corner much faster than when leaning with the machine.

Top Gear Ratio.

I should be obliged if you would tell me the number of teeth required on the engine sprocket to get the ratio of 5 to 1. I have a 6 h.p. Jap engine running with a Sturmey-Archer gear box to an 18in. belt rim. The clutch sprocket has thirty teeth, belt pulley 8in., on S.A. gear.—A.E.R.

With the belt pulleys and countershaft sprocket you have it will be impossible to obtain a 5 to 1 gear ratio exactly. With a fourteen-tooth engine sprocket and the others as stated, the top gear would be 4.8 to 1; with a thirteen-tooth engine sprocket the top gear would be 5.17 to 1. Probably the latter will suit you.

Coil Ignition.

I have a 3½ h.p. motor cycle engine which I want to use for stationary purposes. I also have an eight volt, 100 ampère accumulator for ignition. I should like to know if it is absolutely necessary to use a coil in order to produce a spark at the plug; also, if necessary, would the coil act as a contact breaker, or should I want a separate commutator?—F.D.

It would be much more satisfactory to use a magneto, as coil ignition is not nearly so reliable. Should you decide to persevere with this idea, however, it will be necessary for you to obtain a coil. The coil will not act as a contact breaker, and a commutator is not used at all.

A Matter for Deduction.

I have a Bosch magneto fixed to a twin-cylinder 50° Precision engine on a Ranger cycle car. The car is most difficult to start, though, if pushed a yard or two, it both runs and pulls well. Could you inform me if the magneto is a suitable one? I have searched for the degree number, but cannot find it. Is it possible that it might be for 180°? Would the car run at all with one of that degree? Would you advise me to get a new magneto, or have this one thoroughly overhauled by a competent firm?—H.G.M.

If the engine will run on both cylinders at all, it is obvious that the magneto is of the correct angle to suit it. The old type magnetos were not usually marked with the angle. We should advise you to have the magneto overhauled; also attend to the carburetter, eliminating air leaks between it and the engine, as this may have something to do with the difficult starting.

Converting a Cycle.

With reference to an article which appeared in one of the recent issues of *The Motor Cycle* about an Auto-wheel which was fitted into a bicycle, forming both a power unit and a rear wheel, I should be obliged if you would let me have particulars and instructions as to how the Auto-wheel was fitted and fixed in the frame, so that I could fit one into my bicycle?—H.M.

We are unable to give you any further particulars regarding the fitting of an Auto-wheel into a cycle frame. These arrangements are usually the result of experiments by enthusiastic amateurs, but as the construction does not appear to be particularly complicated, we think that a little experimental work on your part would quickly indicate the best method of using this device.

EXPERIENCES WANTED.

"A.S." (Wimbledon).—5 h.p. Brough, horizontally-opposed twin, as regards speed, consumption, ease of starting, hill-climbing, and general reliability, with sidecar.

RECOMMENDED ROUTES.

WORCESTER TO PURLEY.—R.A.D.

Worcester, Pershore, Evesham, Broadway, Moreton, Chipping Norton, Woodstock, Oxford, Wallingford, Reading, Wokingham, Staines, Kingston, Sutton, Purley.

LONDON TO FLAMBOROUGH.—E.H.J.

London, Ware, Royston, Eaton Socon, Buckden, Stilton, Peterborough, Market Deeping, Bourn, Sleaford, Lincoln, Brigg, New Holland (ferry), Hull, Beverley, Great Driffield, Flamborough.

BIRMINGHAM TO BARMOUTH.—T.W.G.

Birmingham, Chester Road, Brownhills, along Watling Street to Shrewsbury, Oswestry, Corwen, Bala, Llanelltyd, Barmouth.

BOURNEMOUTH TO CARDIFF, AND THENCE TO LONDON.—T.B.R.

Bournemouth, Christchurch, Fordingbridge, Salisbury, Heytesbury, Warminster, Bath, Nailsworth, Gloucester, Lydney, Chepstow, Newport, Cardiff. Return *via* Newport, Usk, Monmouth, Cinderford, Westbury, Gloucester, Cheltenham, Northleach, Witney, Oxford, West Wycombe, High Wycombe, Beaconsfield, Uxbridge, Ealing, London.

WELLINGBOROUGH TO BLACKPOOL.—W.R.

Direct route, passing through very busy districts: Wellingborough, Kettering, Oakham, Melton Mowbray, Nottingham, Ripley, Matlock, Bakewell, Buxton, Stockport, Manchester, Bolton, Preston, Blackpool. This route is rather difficult on the Matlock-Manchester section, and, if time is no object, would suggest going *via* the Great North Road. Wellingborough, Kettering, Stamford, Grantham, Newark, Retford, Doncaster, Tadcaster, Harewood, Otley, Skipton, Settle, Ingleton, Lancaster, Garstang, Blackpool. This route avoids all large towns, has good surface, but one or two stiff hills.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns First 12 words or less 2/-, and 2d. for every ditional word. Each paragraph is charged parately. Name and address must be counted. ies discounts, conditions, and special terms regular trade advertisers will be quoted on plication.

Postal Orders and Cheques sent in payment for vertisements should be made payable LLIFFE & SONS Ltd., and crossed & Co. easury Notes, being untraceable if lost in nsit, should not be sent as remittances.

All advertisements in this section should be ompanied with remittance, and be addressed the offices of "The Motor Cycle," Hertford eet, Coventry. To ensure insertion letters uld be posted in time to reach the offices of he Motor Cycle," Coventry, or London (20, dor St., E.C.4), by the first post on Friday rning previous to the day of issue.

All letters relating to advertisements should ote the number which is printed at the end of ch advertisement, and the date of the issue which it appeared.

The proprietors are not responsible for clerical printers' errors, although every care is taken avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be ressed to numbers at "The Motor Cycle" Office. en this is desired, the sum of 6d. to defray the cost of stration and to cover postage on replies must be added the advertisement charge, which must include the ds Box 000, c/o "The Motor Cycle." Only the number appear in the advertisement. All replies should be ressed No. 000, c/o "Motor Cycle," 20, Tudor Street, .4. *Replies to Box Number advertisements containing ittances should be sent by registered post, but in all such s it is advisable to make use of the Deposit System.*

the case of motor cycles offered for sale under a box aber, as it is unusual for these to be sold without first g inspected by the intending purchaser, advertisers will litate business by embodying in their advertisements e mention of the district in which the car offered be seen and tried.

DEPOSIT SYSTEM.

ersons who hesitate to send money to unknown persons deal in perfect safety by availing themselves of our osit System. If the money be deposited with "The or Cycle," both parties are advised of this receipt. he time allowed for a decision after receipt of the is is three days, and if a sale is effected we remit the unt to the seller, but, if not, we return the amount he depositor, and each party to the transaction pays iage one way. For all transactions up to £10, a osit fee of 1/- is charged; on transactions over £10 under £50, the fee is 2/6; over £50 and under £75, 5/-; £75 and under £100, 7/6; and on all transactions £100, ¼ %. All deposit matters are dealt with at Tudor Street, London, E.C.4, and cheques and money ers should be made payable to Iliffe & Sons Limited. he letter "D" at the end of an advertisement is an cation that the advertiser is willing to avail himself of Deposit System. Other advertisers may be equally rous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no wer to their enquiries are requested to regard the ice as an indication that the goods advertised have ady been disposed of. Advertisers often receive so y enquiries that it is quite impossible to reply to one by post.

"CURED."

Have you ever had a valve break, a belt break or slip, a saddle spring break, a spoke break, your back break—yes, or back "brake." if you like?

Ever used cheap butted tubes?

Ever had an engine misfire, overheat, vibrate, run on one cylinder only?

Recollect running up and down trying to get the other cylinder to "chip" in?

NO!

What! do you mean to tell me that you have never suffered from one of the above troubles?

NO!!

Then you are either a L . . . ikely buyer of a machine on which those ailments are non-existent, or you are not. If you are, then it is a Stamped Steel

Black Prince

The machine that is totally unorthodox, so utterly different.

WRITE FOR DETAILS.

More about it next week.

The "IVY" TWO STROKE

OLYMPIA.

Our Stand is

No. 91

Ground Floor,

where we shall have on view the 1920 productions of our famous two-stroke machine. We extend to all a hearty invitation to visit us there, when the reason WHY THE IVY is "The Aristocrat of its Type" will more than ever become apparent.

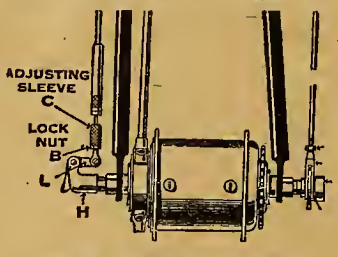
ADJUSTMENT HINTS.

HOW TO ADJUST THE ARMSTRONG GEAR.

1. Take out screw A, pull control lever over to the adjusting position (see illustration), and insert the screw in the hole marked E, this will retain the operating lever in a neutral position.
2. Unscrew the lock-nut B and turn the knurled adjusting sleeve C until you find the free or neutral position, by revolving the back wheel by hand; meanwhile the clutch should be in the driving position.
3. When the free position is found, replace the screw A in the lever D, and re-fasten the lock nut B securely.
4. IT IS IMPORTANT that operating mechanism H is screwed on the spindle the correct distance so that the PUSH ROD LEVER L rests upon the spindle thread within 1/32 part of an inch; this is to ensure correct transmission to the push rod inside the main spindle.



When sending repairs:-

1. It is advisable to send a complete wheel.
2. It is essential that outside fittings such as axle nuts, gear or clutch operative parts, washers, etc., are NOT sent.
3. A letter advising as to date despatch, station sent from, and mark and number of hub should be posted, and, MOST IMPORTANT, two labels bearing sender's name and address on reverse of both should be tied to the wheel.
4. Kindly note we do not supply interior parts.

HOME

BOOT

REPAIRING

"Elite Holdtite Rivetless Soles."

Soles STUCK ON

We are now placing on the market an entirely new and Patented Rubber Sole. These soles are specially prepared with an adhesive surface, and fixed with Elite Holdtite Sol-fix solution. **We guarantee them to hold as firm as rivets or sewing.** The process of fixing is exactly the same as that of repairing a punctured Motor or Motor Cycle tube. One of the many great advantages of our process is that the Boots or Shoes when fitted with our soles become **absolutely waterproof.** Full instructions given with each pair of soles

Road Warning Signs.

THE overlapping of activities of the various motoring associations has often been discussed in our Correspondence columns, readers chiefly pointing out the Gilbertian situation arising from the clashing of the road service organisation and the patrol systems of the leading bodies.

For our part, we consider that the position is not nearly so urgently in need of strong criticism in this respect as is the redundant sprinkling of our roads with all manner and variety of danger warnings. This question is one which affects a wider circle than that comprised by the motoring associations, since, not only they, but innumerable town and rural district councils, as well as private individuals, have taken upon themselves the erection of warning notices of varying degrees of utility and legibility. Had these all been posted at truly dangerous places, and had their variety been enlivened by the somewhat gruesome fancy which impels our American cousins to exhibit a skull and cross-bones device at the beginning of some particularly lurid stretch, we need not have much cause for complaint, either as to the meaning conveyed or against the monotonous method of conveying it; but with us the same red triangle is used indiscriminately to indicate the proximity of a veritable death-trap bend or the existence of somebody's dog-kennels some half-mile back from the highway.

Government Control.

Perhaps the Minister of Transport, under whose eye the questions of road traffic problems must come, will endeavour to unify a system of road signs which will expedite the safe passage of fast vehicles on our roads, for it must be remembered that the communication between town and town and village and village was planned in a day when the requirements of speed were undreamed of, and that now a complex system of warnings has arisen either as the result of local effort or (chiefly) by virtue of the motorists themselves through their organisations.

This state of affairs leads to considerable abuse, the needless installation of warning signs giving no proportionate idea of the danger indicated and much unnecessary overlapping. Thus a particular bend, insufficiently severe to be in the least dangerous, is adorned with a warning triangle at the instance of local influence entirely anti-motoring in its attitude; the same warning is also exhibited at the crossing of two great highways where frequent accidents have occurred. The motorist, having needlessly decelerated at the first, is a little inclined to chance the second, and perhaps an accident, or a narrow escape, results. A system such as is in vogue in many parts of the Continent, and some of the American States, which indicates the nature of the danger by easily discernible signs representing in bold and elementary patterns the reason for an exercise of caution, gives the motorist at once a definite idea of the amount of risk he runs when he ignores its warnings.

A More Comprehensive System.

One such system consists of signs which are obvious in their intent. A village school is suggested by a simplified pictorial representation; a level crossing by two parallel lines intersected by another at right angles; cross roads and gentle or acute bends by hieroglyphical devices which readily suggest themselves. This method undoubtedly arrests the eye and mind of the driver both more quickly and more convincingly than any combination of words could do.

A central authority controlling the erection of all road warning signs would prevent such things as the posting of red triangles adjacent to the roadside by private property owners whose carriage drives open on to the highway. A notice such as "Concealed drive" is far more effective; but the onus of avoiding accident must remain with the thoughtless driver who enters a main road from a side road or a private drive.

An index to the advertisements in this issue will be found on the page facing the back cover.

OCCASIONAL COMMENTS

BY "IXION"

No Deeper than a Plain Nut.

IN a recent comment I assumed that a locknut necessarily occupied more room than an ordinary nut, and that it was often impossible to fit a patent nut-lock to a stud, bolt, or spindle with a short thread. Vislok, Ltd., assure me that their patent locking device is supplied in exactly the same depth as the ordinary nuts. In other words, if a rider is afflicted by a nut which works loose, he can substitute a Vislok without the least difficulty.

Mr. Bower and the A.C.U. Trials.

MR. BOWER, of Zenith Motors, Ltd., is surprised at my implying that makers should fit modified engines and gear boxes for big trials. Is his tongue in his cheek? He knows as well as I do that an absolutely standard trade entry is a rare bird in such events, though the degree of the departures from standard varies in each case. More probably he is surprised that a journalist should accept the inevitable. Anyhow, I will clear up the principles I have in mind. I would fight tooth and nail to expose and pillory any manufacturer who to my certain knowledge was entering a *good* machine for competitions, and selling a *bad* machine to the public through the advertisement which the trials gave him, and all honest traders would applaud. Yet it by no means follows that a firm's stock machine should be the dead spit of its competition machine. No sane private owner desires a Brooklands machine for road work. In the old days, when an A.C.U. Trial was a straightaway tour over routes carefully selected to dodge all really severe hills, it was desirable that a firm's stock and competition machines should be identical. To-day no such parallel exists. The trials go where no normal person would dream of touring for pleasure. The straightaway ride is interrupted by a series of tests possessing the subtlety of a Faraday House test with little of its accuracy. Riders have to perform stunts of a very arbitrary character on a certain hill. They have to run the gauntlet of Dr. Low's audiometer. They have to submit to the scrutiny of judges, whose personal fads are largely an unknown quantity. None of these canons apply in ordinary riding. A manufacturer is surely justified in faking a machine to earn high marks in the C.D.T., against the audiometer, and under the finishing condition scrutiny. But he is under no compulsion, technical or moral, to fake all his commercial machines in exactly the same fashion. Should his experience of the A.C.U. stunts convince him that the private owner wants what the A.C.U. demands, he will alter his standard specification accordingly. This year the trade (and amateur spectators) wrote down the C.D.T. as a farce; regarded the audiometer with amused benevolence, until they realised its consequences; and were frankly baffled by the mysteries of the concluding "examination."

Hypothetical Examples.

SINCE Mr. Bower's dig at me suggests that I stand on thin ice, from the standpoint of commercial morality, I will elaborate my thesis. It has been suggested in several influential quarters that the C.D.T. shall be repeated in next year's trials with sundry modifications. The notion is that the stunt would be sound if every rider were credited in proportion to the contrast between the slowness of his crawl up the first part of the hill and the speed to which he could accelerate up the second part. This would eliminate the split second nonsense, and, in the opinion of some authorities (who ought to know better), would constitute a very good test as well as a fair knockout for the special prizes. If I had to construct a machine for any such silly business, I should equip it with good cooling, a phenomenally low bottom gear, and a pair of tiny side wheels for steadying the crawl, such as Hayes used to sell on Kerry machines. As an extra precaution I would put a trick rider in the saddle: the kind of man who can balance a push bicycle stationary for half an hour; this in case the judges took a cold chisel and cut my side wheels off. On this outfit my jigger would do the slow climb at about one hundred yards per hour. For the acceleration business up the fast stretch, I would fit every practicable gadget. Preliminary tests might suggest a variable compression valve cap, a variable carburetter jet, and perhaps an infinitely variable gear. If the A.C.U. say to me in effect, "We are awarding prizes for the vastest flexibility in a timed hill-climb," I would come near winning their silly prize. But I should not be such a juggins as to sell the public a machine with side wheels, a 25 to 1 bottom gear, and a number of other freak gadgets for which they have no earthly use. All the public want in the way of flexibility on hills has long since been provided by standard engines, gear boxes, and clutches. In other words, a maker's stock machine should be as good as his competition models; but it need not necessarily be identical with them: in fact, it should *not* be identical with them when competitions include freakish stunts.

Minus the C.D.T.

SEVERAL manufacturers have written to me suggesting that the marks earned in the A.C.U. Six Days should be republished minus the results of the consistent driving test. I have little doubt that the A.C.U. would gladly wash that portion of the event out if it were in its power to do so, for it served no useful purpose other than that of keeping down the number of gold medals. But I would remind malcontents that the prospectus of the trial partakes of the nature of a legal contract, and that the A.C.U. would find itself in rather an awkward position if it attempted to go back on its word. It

Occasional Comments.—

is a great pity, for, if riders had been set to take Panne Hill as slowly as possible on the first day, and as fast as possible on the last day, we should have had some fun. On the whole, I am against any stunt which tempts machines to fail on hills up which they can romp when driven in normal fashion, for we have learnt how hill failures can be misrepresented. Brooklands is probably the only venue where maintenance of tune can be adequately tested.

Automatic Carburetters.

SO far as English machines are concerned, the claims of the automatic carburetter have always been handicapped by manufacturers' preference for a semi-automatic or sensitive type. There is hardly a British machine in existence fitted with an automatic type as standard. The handful of riders who fit Claudels, Everests, and other "conversion" sets is too small to wield any great influence. The average man rides a two-lever type, grumbles about it, and is prevented by his natural inertia from experimenting with the rival simplicities. In the near future this position will be modified. The Americans mostly fit carburetters, which, if not absolutely automatic, come nearer that ideal than our own "semis." Uneasy suspicions that the fondness which many Britishers show for American stuff may be partly due to easy carburation are inspiring a few British makers to adopt the one-lever vaporiser. The A.B.C. machine is to have an automatic as standard, so also is the flat twin Humber. Messrs. H. M. Hobson, Ltd., have improved their vertical type of motor cycle automatic, and are flanking it by a very pretty little horizontal pattern with a neat Bowden control. The Zenith people are sitting up and taking interest: their first motor cycle automatic will be at Olympia.

I have tried many of the above carburetters and a number of others aiming at similar ideals. I am bound to admit that in several cases it was difficult (and in some impossible) to secure as low a petrol consumption as a two-lever instrument affords. But I have never once reverted from the one-lever to the two-lever on any engine. A decrease of, say, 10 m.p.g.—and more need not be dreaded, even in extreme cases—is not too high a price to pay for the absolute certainty of terrific acceleration on demand. Motor cycling holds few more pleasurable sensations than that of a willing engine leaping forward at a touch of the throttle. But one has to know and handle a two-lever uncommonly well to get maximum acceleration on every conceivable occasion without a suspicion of dwell or hang, to be corrected by a final petulant twitch at one of the levers. There would not have been many stoppages in the C.D.T. in September if all the entrants had been driving on automatics.

A Semi-automatic.

OF the two machines now in my stable, one is equipped with the latest vertical Claudel-Hobson, known as the M.I.A., and the other with the semi-automatic, variable jet B. and B., both engines being rated at the same horse-power. The great merit of the B. and B. is that in delivery tune it gave—and has given ever since—110 m.p.g. Since 60% of the extra air is controlled by the throttle valve, the air lever requires the minimum of attention. Nevertheless, a novice would occasionally muddle his mixture on it. I plead guilty to stopping for this elementary reason once a week or so, usually at a blind corner, or in traffic, or perchance on a rough, curly hill. The M.I.A., on the other hand, never gives you a mixture stop, and never loses you a tenth of a second when some other fellow tries to "jump" you on the road and you want to be after him quickly. Yet it is by no means so economical as the B. and B.

I do not suggest that any manufacturer should limit himself to either type. For some years to come the two patterns will probably be distinguished by the features outlined above, viz., automatics for ease of control, two levers for low consumption. These are matters of personal taste. One rider would vote for simple control, another for fuel economy. Why do not the trade give us an option?

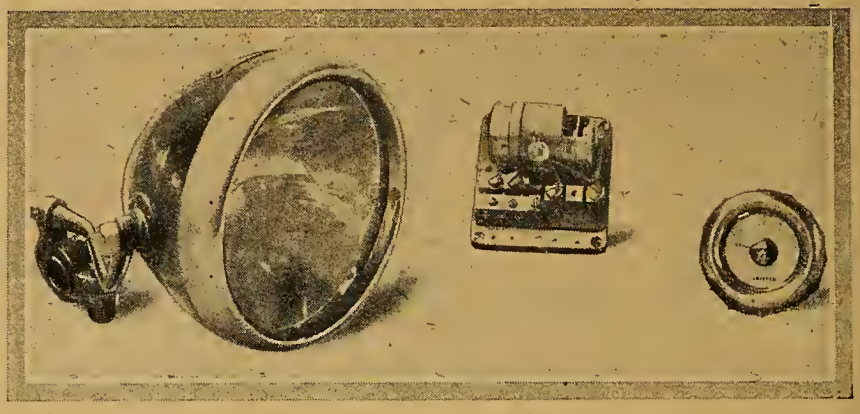
A SCENE DURING THE WHIPPET ROAD TEST LAST WEEK. The journey from London to Brighton, a distance of 53 miles, was successfully accomplished, though it may be assumed that such a demonstration is not the limit of the capabilities of this little mount.

Powell and Hanmer Lighting Set for 1920.

Mechanical Control of the Dynamo Speed, Cables contained in Single Leads, and a Neat Watch Pattern Switchboard.

DYNAMO electric lighting sets for motor cycles are not so numerous as to preclude a hearty welcome to a new comer. In this case, the name of the makers is a guarantee of soundness, and, moreover, the simple construction of the various electrical components used in the Powell and Hanmer set will recommend itself to the motor cyclist. Characterised by careful and solid workmanship—well-made articles are often solid without necessarily being heavy—the new set consists of dynamo, battery, cut-out, switchboard, head, side, and tail lamps. The output is six ampères at six volts at 1,440 r.p.m.

As regards electric lighting for motors, the chief difficulty facing the designer is to reconcile the irregular drive from the engine with the need of a constant output from the dynamo. Two main methods of overcoming this disability are now in use. One is to provide means whereby the electrical output may be controlled and limited, the other is to employ a mechanical device that shall make certain that the dynamo itself never may be driven above a predetermined speed. This last is the principle adopted by Messrs. Powell and Hanmer, Ltd.



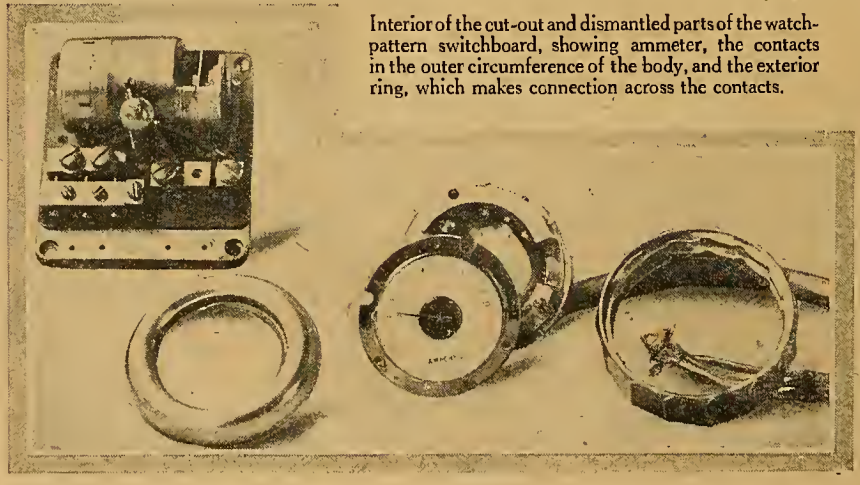
Head lamp, cut-out, and switchboard of the Powell and Hanmer lighting set.

A Governor Clutch Drive.

In broad outline, the limiting device is obtained by interposing between the dynamo pulley and the armature-shaft a spring loaded single plate clutch in such a way that drive passes through the clutch and the clutch spring. If the torque applied to the pulley exceeds the strength of the clutch spring the latter is compressed, and, by means of a cam action, the clutch itself is momentarily disengaged. As soon as the spring is relieved of its load by the freedom of the clutch the latter is at once forced to re-engage. Actually, a floating action takes place, effecting a constant slip, according to the excess of rotational speed given to the pulley.

The design of the clutch itself can be discerned from the accompanying illustrations. Mounted on the armature-shaft is a ball bearing, the outer race of which is contained in the boss of a belt pulley. Free on the extremity of the armature-shaft is a sleeve, which carries at one end a Ferodo-faced plate forming the driven member of the clutch, the Ferodo facing being arranged to grip against the side of the belt pulley. In the sleeve is cut a helical groove, which is engaged by a radially placed pin fixed into the shaft. This device is arranged so that rotation of the sleeve relative to the armature-shaft in either direction causes the former to slide inwards or outwards along the shaft owing to the presence of the pin within the helical groove. This rotation of the shaft in the one direction will cause the clutch plate to be withdrawn; or, in the reverse direction, will cause engagement.

Rigidly attached to the end of the shaft is an annular cover plate, containing a snail or clock type of spring. The outer extremity of this latter is fastened to the inner periphery of the case, and the inner end is attached to the clutch sleeve. As the armature-shaft of the dynamo will offer an increased resistance to turning as its speed is raised, to limit the output of the dynamo it is only necessary to make the clutch slip when the resistance reaches a predetermined limit. If driven below the limit the pulley wheel carries the clutch plate round with it, and through the sleeve the drive is transmitted to the spring, and from the spring to the shaft. If the drive exceeds that required, the load on the armature-shaft, becoming greater, causes the spring to be compressed or wound up. Winding up the spring, however, has the effect of rotating the sleeve relative to the shaft, with the result that the sleeve is moved along the shaft and withdraws the clutch momentarily from engagement.

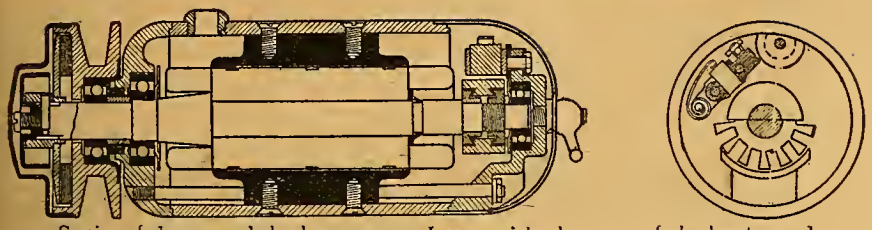


Interior of the cut-out and dismantled parts of the watch-pattern switchboard, showing ammeter, the contacts in the outer circumference of the body, and the exterior ring, which makes connection across the contacts.

A Thoroughly Tested Device.

In actual practice the governor clutch device is a great deal more sensitive than might be imagined. Tests have been witnessed in which one of these dynamos was driven from an electric motor, controlled through resistance coils. The speed of the motor could be varied from 500 or 600 to about 2,000 r.p.m. very quickly, but whether the controller handle was moved slowly or fast only the slightest tremor of the ammeter needle connected up in the accumulator charging circuit with the dynamo could be detected, and this only at or about the critical speed at which the clutch commences to slip. Indeed, when the dynamo was directly coupled to lamps representing the lighting set, with the accumulator out of circuit, sudden variation of the speed of the driving motor produced only the faintest flicker in the glow of the filaments.

It will be conceded that the above constitutes a very severe test. As the actual load transmitted through the clutch is not of a great order, and as the clutch itself is of very reasonable dimensions with regard to that load, the wear on the Ferodo facing is stated to be small, nor does the clutch itself appear to run particularly hot when slipping, due, in all probability, to the sensitiveness of the device. For the foregoing reasons, the rider can afford to forget the existence of the dynamo regulator.



Section of dynamo and clutch governor. Inset on right shows one of the brushes and its spring.

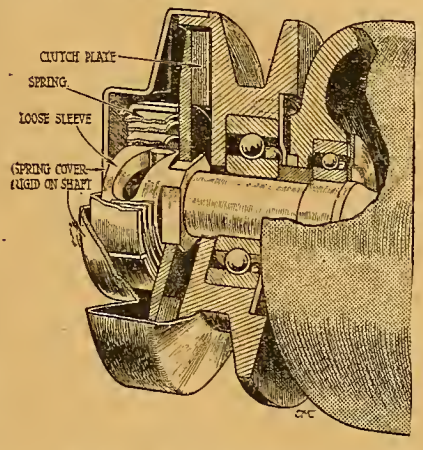
Dynamo Design.

In construction, the dynamo consists of a cylindrical steel yoke piece machined all over, and having attached to its interior two pole pieces, the inner extremities of which form the armature tunnel. Aluminium end pieces carry the self-aligning ball bearings in which the armature-shaft runs, and these end plates are held down on to their registers by means of two bolts extending from end to end of the body. To prevent foreign matter getting into the bearings, the latter are covered with metal backed felt washers, and lubricant to the bearings is supplied through oil cups. The machine is shunt wound, following standard electrical practice, and the core of the armature consists of laminations pressed on to the armature-shaft and kept in position by a key and ring.

The commutator is remarkable for its large proportions, and the segments are dovetailed into position by a coned shoulder and a coned locking ring. In manufacture the commutator segments are assembled within a stout steel ring, and then are bored and the dovetail cone faces cut. The assembly is put in position on the shaft, locked home, and afterwards the outer steel ring is pressed off and the circumference of the commutator skimmed up in position on the shaft. Soft morganite brushes of large dimensions are used, and each is held up to its work by the tangential projection of a coiled clock spring. The brushes are extremely easy to remove, and, owing to their size and the governing action of the driving clutch, sparking and wear are practically negligible. Approximately, this dynamo weighs about 9 lb.

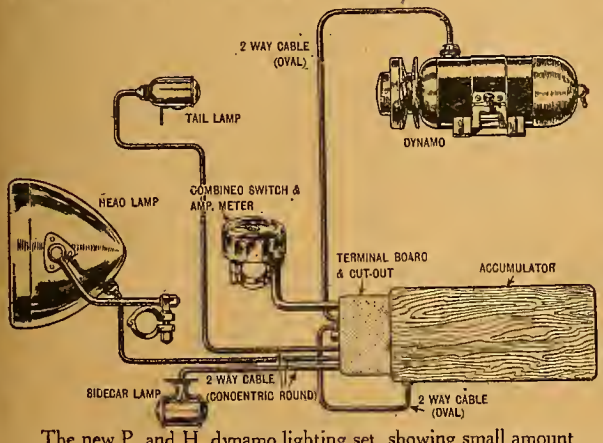
The Cut-out.

Since the function of the dynamo is to charge the accumulators and nothing else, means have to be taken to ensure that current cannot pass from the dynamo to the accumulator until it is powerful enough to overcome any tendency of the accumulator current to reverse, and to endeavour to run the dynamo as a motor. Hence the dynamo must not attempt to charge the accumulators until it is producing a definite amount of electrical energy. To achieve this purpose, a "cut-out" is employed. As will be seen from the illustration, the type used in the Powell and Hanmer set consists of an Ironclad series and shunt-wound electro magnet, and when the latter is excited to the necessary degree its core attracts a spring-loaded armature. This armature carries a platinum point, which makes contact with a second fixed point and completes the charging circuit. The tension of the flat spring carrying the armature normally holds the platinum points apart, and determines the strength to which the magnetic field of the cut-out must be built up by the dynamo before the cut-out cuts in and allows charging to take place.



Section of the driving pulley showing friction plate.

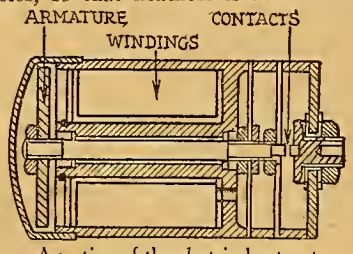
It has been stated that the cut-out is both shunt and series wound. The shunt winding is energised from the dynamo, and the series winding from the accumulator and dynamo. Thus if the dynamo slows down sufficiently to allow reversal of current to take place from the accumulator, the series winding in the cut-out reverses its magnetic field, and acts against the shunt winding, with the result that the effective pull of the cut-out against its armature is reduced, and the spring of the armature causes the latter to leave the core and thereby break off the connection between dynamo and accumulator circuit.



The new P. and H. dynamo lighting set, showing small amount of external wiring.

Switchboard.

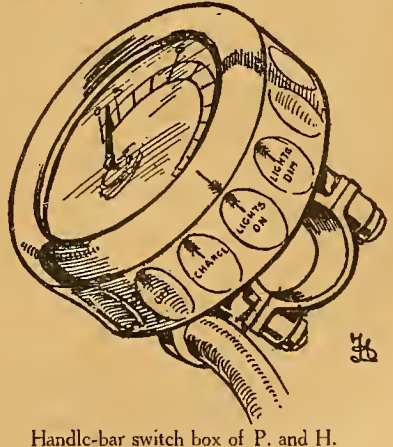
A feature about this lighting set which is certain to find favour with motor cyclists is the extremely compact form of the instrument board. It consists merely of a fitting very little larger than an old-fashioned heavy watch, which fitting can be clamped on to the handle-bars in any suitable position, or on the top tube or elsewhere. Only one lead runs from it containing all the necessary cables, so that neatness is assured. The centre of the instrument houses an ammeter, but the outer circumference of the casing can be rotated and forms in effect the switch, giving the various positions of charging, head light, side light, tail light, and dimmer. An idea of the internal construction can be gathered from the illustrations.



A section of the electrical cut-out.

Lamps.

Considerable attention has been paid to the construction of the lamps, which can be obtained in nickel, black, or nickel and black finish. The head lamp is shown in an annexed illustration. To prevent any trouble with the lamp front and glass, a special form of attachment is used, consisting of a semi-hinge at the top and a vertical taper plug bolt at the bottom, the latter being made fast with a milled nut. In the event of the nut shaking loose through vibration, the front of the lamp cannot swing open. The bayonet socket of the bulb is attached to the body in a manner which allows of proper focussing of the light beam, the socket being locked into place by means of a screwed ring.



Handle-bar switch box of P. and H. lamp set.

THE 1920 BRADBURY PROGRAMME.

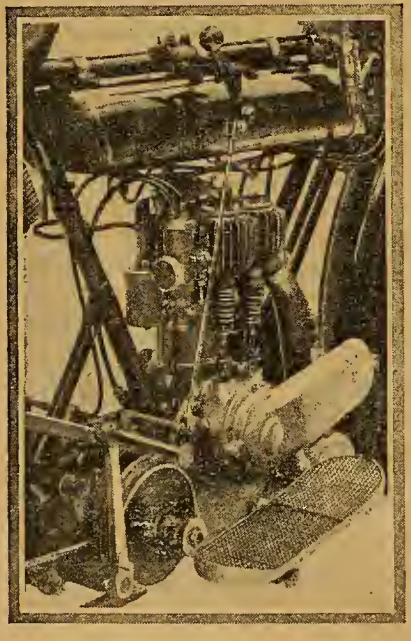
Three Types: 2¾ h.p. and 4 h.p. Singles and 6 h.p. Two-cylinder Models.

ONE of the oldest firms in the motor cycle industry, the famous Lancashire firm of Bradbury and Co., Ltd., of Oldham, has deservedly held an enviable reputation for the staunchness of its productions, both as regards engine power and frame design.

The main lines of previous models will be followed in the 1920 output of the firm, but one type, new to the general public (it was briefly described in *The Motor Cycle* of March 2nd, 1916), is now being brought forward.

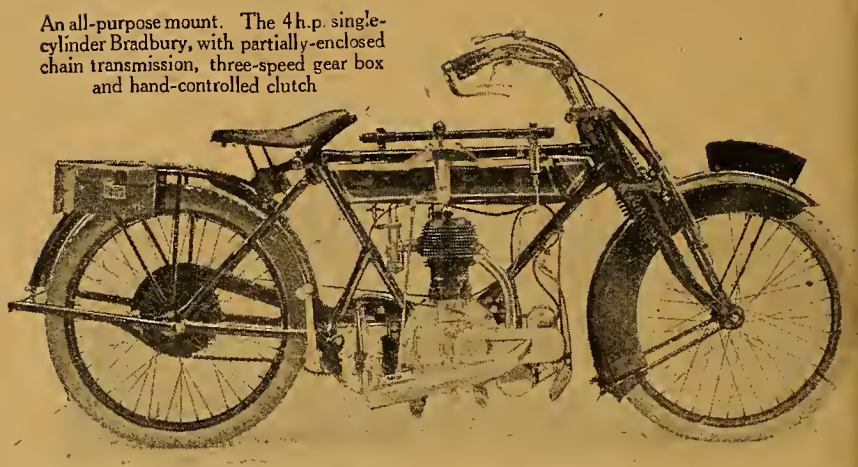
The 2¾ h.p. Lightweight.

This is of a type which will fill a gap in the market, since it is a homogeneous design, carried out entirely as the production of the firm who market it. Many motor cyclists do not care to have a machine built around a proprietary engine, preferring one in which the unit is exclusive to the particular make favoured, and, so far, they have not been able to indulge their fancy in this direction so far as small single-cylinder four-strokes are concerned.



Engine unit of the new 2¾ h.p. Bradbury lightweight. Note the duplex frame tubes, detachable cylinder head, and clutch in the countershaft pulley. A picture of the complete machine appeared in last week's issue.

An all-purpose mount. The 4 h.p. single-cylinder Bradbury, with partially-enclosed chain transmission, three-speed gear box and hand-controlled clutch



The bore and stroke are 74.5 × 80 mm. respectively, the cylinder having a capacity of 349 c.c., the crank case being incorporated in the frame in the same way as that of the old-established 4 h.p. model. A detachable head is fitted, and this is held by long bolts and a bridging piece similar to those employed on the 6 h.p. engine. It will be seen, therefore, that the best points of previous Bradbury practice and experience are incorporated.

Adjustable tappets are used, and large diameter taper springs return the valves to the seatings. The timing gear is simple, and only has one half-time wheel, while a neat external exhaust valve lifter acts upon a large disc on the tappet stem. Carburation is effected by a top-feed B. and B., and a C.A.V. magneto, chain-driven, is carried before the engine above the cast aluminium silencer.

Frame Design.

The frame is exceedingly neat, being somewhat of a departure from standard practice. Its most noticeable feature is the duplex front tube. Following the design of the 4 h.p. frame this model dispenses with the usual tube under the tank, and has a straight top member free from bends, from which the tank is suspended by clips. This construction is not unduly high, and the Brooks saddle sits quite low at the rear angle of the frame. Commendable features are the employment of long tapered lugs and the short strengthening strut above the gear box bracket.

Transmission.

The power is transmitted to the road wheel through a two-speed box, chain-cum-belt drive being employed. A handle-bar controlled clutch is fitted in the large diameter belt-pulley on the gear box, while the gears are changed by a small lever working on a bracket attached to the top tube.

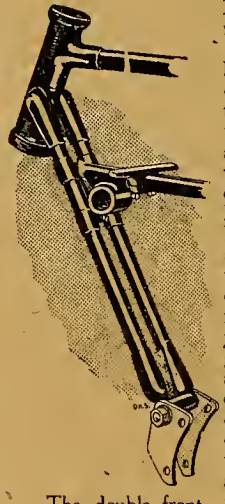
A smart tank, with rounded sides, is fitted, and this is equipped with a Best and Lloyd semi-automatic oil pump with sight-feed regulator.

The 4 h.p. Single.

This well-tried machine, equally suitable for solo or sidecar work, is justly popular. In the past the powerful "square" engine (89 × 89 mm. bore and stroke = 554 c.c) has earned a world-wide reputation for its slogging powers under adverse conditions. It now reappears with various detail improvements, all-chain drive, and three-speed countershaft gear. Constructional details remain the same as in the pre-war models, with the exception of the fact that Druid Mark II. forks are fitted, and that the frame embodies a short stay from the gear bracket to the saddle tube.

All-chain Drive.

A B. and B. carburetter is fitted, and Thomson-Bennett magneto. Lubrication is by Best and Lloyd semi-automatic drip feed.



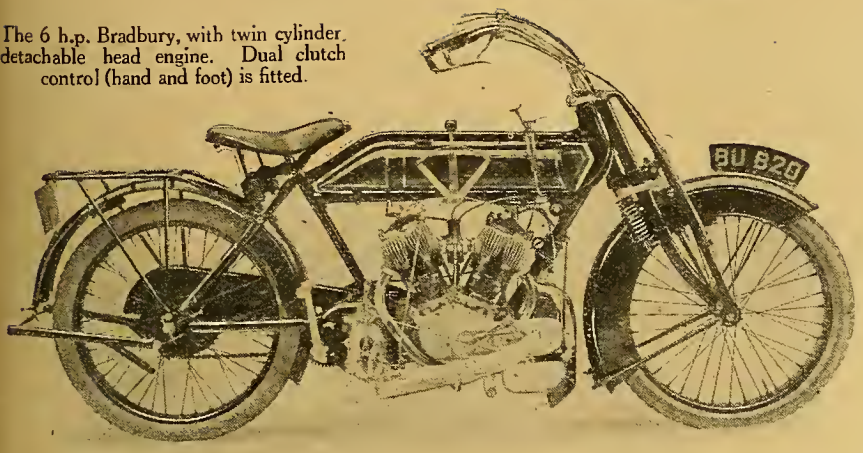
The double front down tube fitted to the 2¾ h.p. and 6 h.p. models.

Transmission is by chains throughout, the Bradbury three-speed gear with kick starter and clutch being used. A Bowden control from the left handle-grip releases the clutch, and it is noteworthy that the operating mechanism and cable adjustment on the gear box are easily accessible. The chains are partially enclosed, having a complete cover between the engine and gears, but only a guard over the top of the final drive, and an internal expanding brake operates in the rear wheel sprocket. A large shield before the magneto, long aluminium footboards, and a Brooks saddle respectively ensure the cleanliness and comfort of the rider.

The 6 h.p. Passenger Model.

As a powerful mount, suitable for sidecar work in any district, the 6 h.p. V twin Bradbury has acquitted itself well. Little change has been found necessary in the general design of the machine, although a new type of frame is used embodying duplex front tubes such as are fitted to the 2¾ h.p. model.

Engine details remain the same, the bore and stroke being 74.5 × 86 mm. = 749.75 c.c. The neat cylinders, with de-



The 6 h.p. Bradbury, with twin cylinder detachable head engine. Dual clutch control (hand and foot) is fitted.

tachable heads, are held by long bolts and bridges as heretofore.

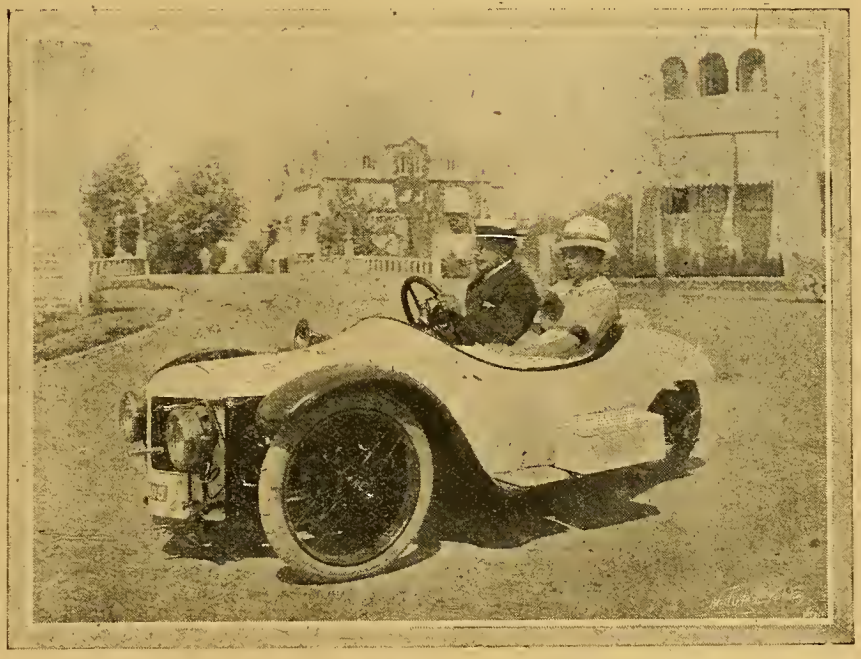
Chain transmission is used throughout with the well-tried sliding pinion three-speed gear. A combined hand and foot control is fitted to the clutch, this being a point of great convenience, since both forms of clutch control have their advantages, especially when traffic driving with sidecar. In general specification this model resembles the 4 h.p. single, except that the rear chain guard is deeper and that a quickly detachable rear wheel is fitted. The Grindlay spring wheel sidecar is fitted to these machines when required, this make having been adopted by the Bradbury Co. as standard for its 1920 specification. The finish on these machines receives much attention, and is of high order, the rounded tanks, enamelled black with a broad gold line, being particularly handsome.

A Dutch Three-wheeler.

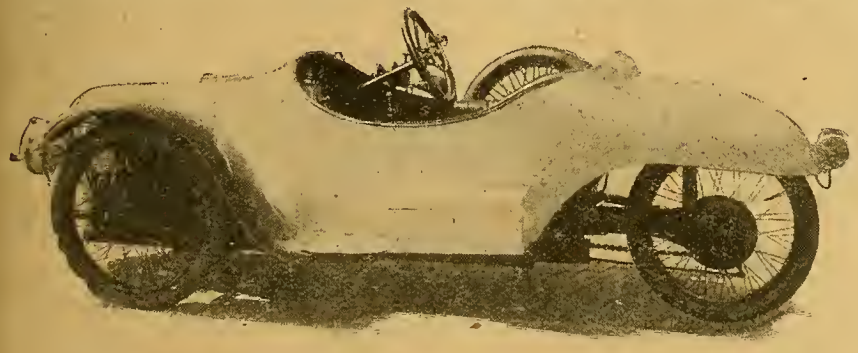
1920 Model Simplex produced by a Leading Amsterdam Firm.

THE three-wheel runabout type of machine has fascinated designers of most countries, but so far the only successful designs have been produced in England. America has been responsible for several novel designs, but at the present time there are none being sold in any quantities. France introduced three-wheelers long ago, as did Germany, but the majority had only a meteoric existence, as have most of the English designs. Of pre-war types, the Morgan seems to be the sole survivor, and to its success may be attributed the present-day popularity of the three-wheeler among designers. Few of these, however, are yet on the market, and they may be regarded as 1920 propositions. Among these is the new Simplex runabout produced by the Simplex Cycle and Motor Co., of Amsterdam—a more or less well known Dutch firm of motor cycle manufacturers.

As will be seen from the accompanying illustrations, the Simplex three-wheeler has a body which compares favourably with any three-wheeler produced in this country. Probably an English designer would have included a hood and screen, since one of the advantages of the three-wheeler over the sidecar is the possibility of affording protection from the elements for the driver. However, this omission may be rectified in production models.



The Simplex on the road. The position of the starting handle will be noted.



The Simplex three-wheeled cycle car, a Dutch production with body design of note.

Specification.

The specification of this machine includes a channel frame underslung at the front, the engine being carried in front of the axle and driving a three-speed and reverse gear box by means of a chain. The final drive, too, is by chain.

A water-cooled V twin engine of 10 h.p. provides the power, the radiator being placed at the rear of the engine and bonnet.

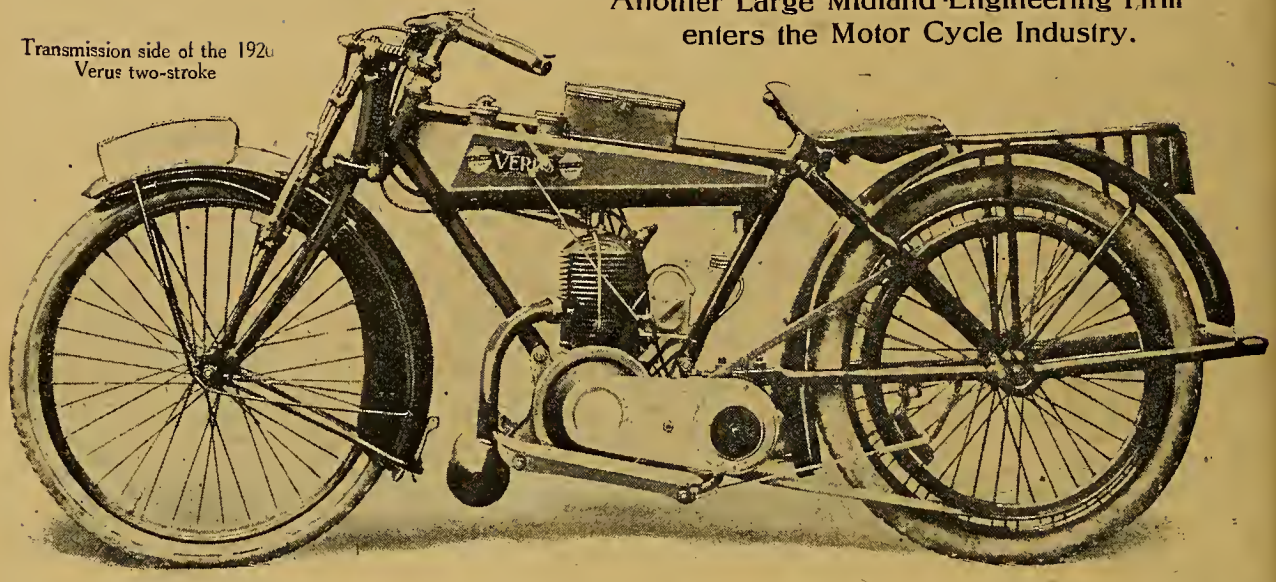
The rear wheel is suspended by quarter-elliptic springs, and may be detached without disturbing the transmission.

Quickly detachable and interchangeable wheels shod with 700 × 85 mm. tyres are fitted, while a spare wheel is carried on the right-hand side running board, a large tool box occupying a similar position on the other side.

The petrol tank is at the rear of the seats, and is constructed as part of the body panelling.

VERUS MOTOR CYCLES.

Another Large Midland Engineering Firm enters the Motor Cycle Industry.



Transmission side of the 1920 Verus two-stroke

CONSIDERING the standing of its manufacturers, the Verus two-stroke made its *début* to the motor cycle world in a very unostentatious manner. Among the array of competing machines in the London-Edinburgh event at Whitsuntide lined up at Highgate, a little Verus attracted attention, firstly because it bore a new name, and secondly on account of its smart appearance. Few realised, however, that it was more than an "assembled" two-stroke machine; that its manufacturers, Messrs. Alfred Wiseman, Ltd., Glover Street, Birmingham, have works covering three and a half acres of ground; and that, with the exception of the gear box, it was produced throughout by its makers, who have plant to make all stampings, castings, and machined parts. In fact, Messrs. Wiseman handle everything from ore to complete machine, excepting the tubes and equipment. In addition, they have their own laboratory, a hardening department, and a plant for hydraulic forging. For several years, Messrs. Wiseman have made two-stroke engines for the trade, while their business in cylinder casting, machining, and grinding has been very extensive.

A Disastrous Fire.

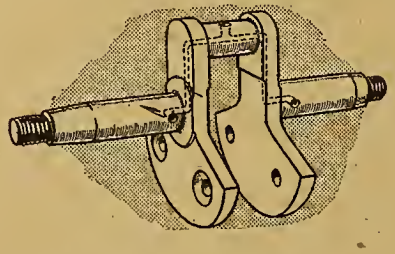
With such facilities and experience, it is not surprising that this firm became interested in the production of a first-class motor cycle, and a lightweight four-stroke was already designed when the Armistice was signed. By January all tools, jigs, and plant were ready to produce this model on a large scale, and parts for a thousand engines were in stock. Then a fire wiped out the works containing the department, and the only thing which escaped was one engine which happened to be in one of the other works. Drawings, patterns, tools, jigs, and stock, including over five hundred magnetos, were lost, and the machine in consequence must lose its place in the 1920 models which will be shown at Olympia.

Despite this set-back, however, quite a large number of Verus two-strokes have been sold during the present year, as it was found possible more quickly to reorganise to build the two-stroke engine, and recently an extension to the works was acquired, which shortly will place the company in a position to recommence on the lines laid down early this year.

The 1920 Models.

Recently we were afforded an opportunity to examine the 1920 models, which include a new 2¼ h.p. two-stroke single gear machine, a 2½ h.p. two-stroke with two-speed gear, a 2¾ h.p. Blackburne-engined four-stroke for solo use, and a 4 h.p. machine, also with a Blackburne engine, as a dual purpose mount. The last machine is not quite ready, but it is expected to be staged at Olympia.

The 2¼ h.p. engine is an exceptionally neat little unit, with a piston displacement of 211 c.c., the bore and stroke being 62 mm. and 70 mm. respectively. It is of the conventional three-port type, having a one-piece crankshaft and split bronze bushed big end. Balance weights are fitted on the inside of the crank webs, and the main shafts run in longer plain bearings than are usual.



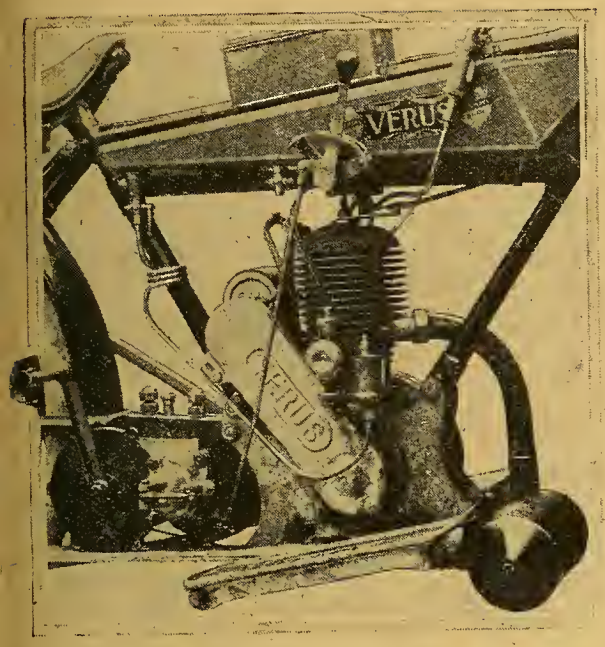
The one-piece crankshaft of the Verus two-stroke engine.

Lubrication System.

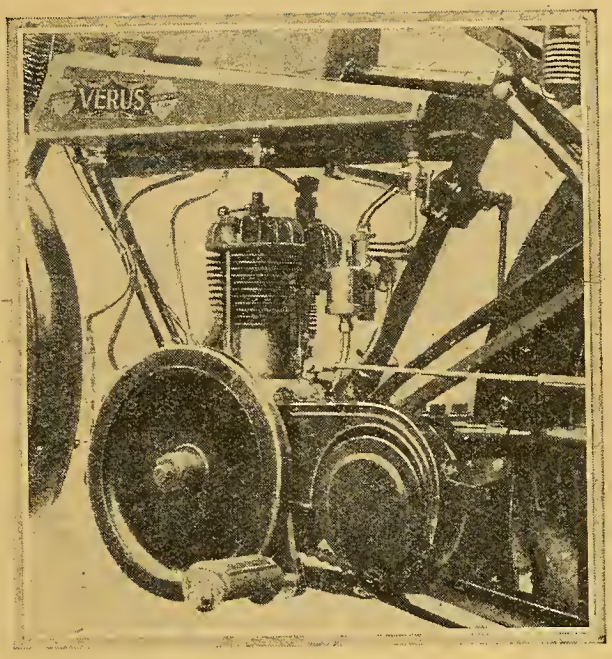
Mr. T. Weaver, who has been very successful on Verus machines in this year's competitions, and who is chiefly responsible for the designs, places the question of lubrication first in the essentials of the efficient two-stroke. (Incidentally, he also believes in a comparatively light cylinder casting as a means of eliminating overheating.) The Verus lubrication system is simple, but quite good. From a drip feed on the tank, oil is fed into an orifice in the side of the cylinder registering with the hollow gudgeon pin when the piston is at the bottom of the stroke. This ensures that the small end of the connecting rod and the cylinder walls receive their proper share of the lubricant. When the oil entrance is uncovered by the piston rising in the cylinder, the oil drains into a well in the top of the crank case communicating with the two main bearings by vertical ducts in the crank case casting. The crankshaft webs and crank pin are drilled, and oil passing into the shaft on either side is thrown up into the big end by centrifugal force. Thus the higher the engine speed, the more would be the supply of oil at this important point.

In the Verus engines, the magneto, chain-driven from the right side, is carried on a bracket, which is integral with the crank case, at the rear of the cylinder. Provision is made for magneto adjustment by the bracket being slotted for the securing bolts.

Unlike most two-strokes having a single exhaust outlet, the exhaust pipe is not "cranked," but leaves the cylinder a little to the side of the centre line at an angle, thus obviating sharp bends. The silencer consists of a large steel barrel.



Details of the Verus two-stroke—engine capacity, 269 c.c



The Verus lightweight fitted with a 2¾ h.p. Blackburne engine.

The larger model has a bore and stroke of 70 mm. (269 c.c.), and follows the 2¼ h.p. model almost at every point. In fact, the same crank case, crankshaft, and connecting rod are used. Amac or Senspray carburetters are fitted, according to requirements, while experiments are being made with a new single lever instrument known as the Walker.

On the two-speed model, a Burman gear box with clutch and pedal starter is used, and driven by chain from the outside of the flywheel, a neat aluminium casing covering the chain and serving also partly to "box in" the flywheel.

The framework is very good, embodying a diagonal top tube and Brampton forks. A shapely tank, distinctively decorated, on the top of which is carried a metal box, can be used either for tools or those oddments which usually have to be carried in the pocket. Almost straight handle-bars, approximating very closely to the D.R. type, form part of the standard equipment. The tyres are 26×2¼in., and the mudguards of ample width. With Brooks or Xl'All saddle, the price of the two-speed 2½ h.p. model is £75; while the smaller machine will be under £60, but 24×2in. tyres are fitted, and the transmission is by belt direct.

Blackburne Engined Models

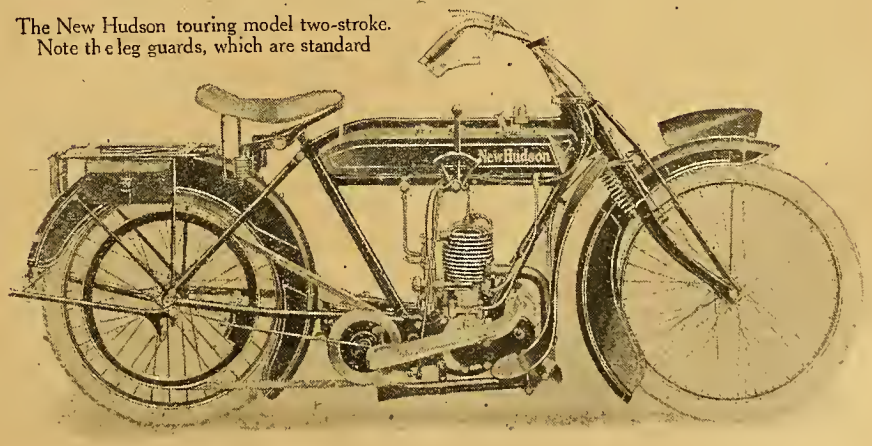
Very similar to the 2½ h.p. machine in its main details is the third model, engined with a 2¾ h.p. Blackburne power unit, which with a Sturmey-Archer gear box is to be catalogued; and a larger model, with the 4 h.p. single-cylinder Blackburne, for solo or sidecar work, will complete the Verus range for the time being. We think this new make will speedily attain a place in the front rank of modern motor cycles. as it is evident from a visit to the works that the three main essentials for success are behind its production. First, the makers are in a position to turn out a good machine; secondly, the men who are directly responsible for the designs are practical motor cyclists; and thirdly, the head of the firm so fully appreciates the desirability of giving satisfaction that a most complete system of inspection is insisted upon at the expense of a restricted output. Mr. Alfred Wiseman, the head of the firm, is to be congratulated upon the adoption of this policy, especially at a time when there is such great temptation to consider "output" the first consideration.

The New Hudson Motor Cycle for 1920.

Well-known Company Re-introduce Small Lightweight.

BEFORE the war, New Hudson motor cycles enjoyed a reputation quite in keeping with the standing of the firm in the world of wheels. So thoroughly did the company enter into the production of war material, however, that the output of 1919 motor cycles was very restricted, and chiefly confined to the lightweight model. It will be recalled that up to 1915 the New Hudson company made two other types which became very popular, *i.e.*, a single and a 6 h.p. twin for sidecar work, and it is with regret we hear that, for the present at all events, these models will not be manufactured. A little later on perhaps a new passenger machine may be introduced, but for the present the works are concentrating upon a small lightweight model, similar to the model made previously, but embodying certain refinements which will make a strong appeal to buyers of lightweights.

The New Hudson touring model two-stroke. Note the leg guards, which are standard

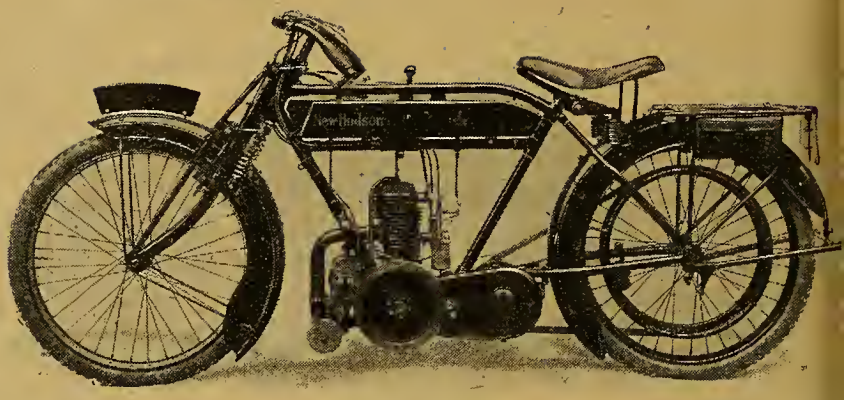


The New Hudson Motor Cycle for 1920.—

This little New Hudson is one of the best finished machines we have examined, and, with its black and dark brown finish, relieved with gold lines on the tank, it looks exceedingly smart. The engine fitted has a bore and stroke of 62 mm. and 70 mm. respectively, the piston displacement being 211 c.c. Two features of the engine which at once attract attention are the compression release and the method of fixing the exhaust pipe.

The first-mentioned device consists of a mushroom valve placed in a vertical position in the centre of the cylinder head, and operated by a rod worked by a bell crank lever carried on a member fixed to the horizontal tube of the frame directly under the tank. A small tube takes the release gas down to a position near the bottom of the crank case.

A large union nut of the castellated type is used to fix the exhaust pipe, instead of the more usual method of making the exhaust pipe and flange integral and fixed by means of studs. The actual flange is fixed in the usual manner, and is quite easy to detach when the cylinder is removed.



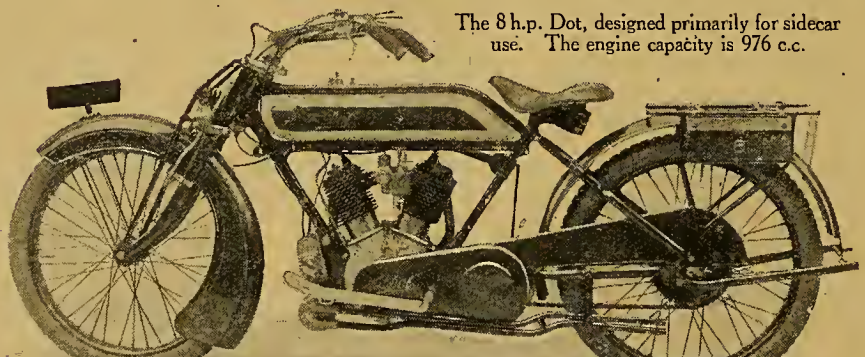
The sporting model New Hudson. This machine has all black finish.

As the machine is provided with 24×2in. wheels, the riding position is very low—a point appreciated by a large number of riders who use such machines for general utilitarian purposes, while ladies will find it most convenient to mount.

Two models are being made: a touris with aluminium footboards, upturne bars, and leg guards, and a sportin model with semi-T.T. bars and footrest Both machines are adequately muc guarded and the chain case is an oi tight unit.

DOT MACHINES FOR 1920.

2¾ h.p. Light Solo and 8 h.p. Sidecar Models.



The 8 h.p. Dot, designed primarily for sidecar use. The engine capacity is 976 c.c.

A SMART all-red lightweight machine is being manufactured for 1920 by Messrs. H. Reed and Co., Manchester, makers of the well-known Dot motor cycles, and it was illustrated on page 485 of *The Motor Cycle* for October 23rd.

It is a four-stroke model, and is equipped with the popular 2¾ h.p. single-cylinder J.A.P. engine, Amac carburetter, and E.I.C. magneto, the latter having a handle-bar timing control.

Neat Frame Design.

Transmission is by chain and belt, through an Albion two-speed box, the gears being changed by a lever at the side of the tank.

The frame is very sturdy, has neat engine supporting lugs and a minimum of clipped-on parts, even the carrier stays being so arranged as to encircle and carry the tool-bags. Saxon spring forks are fitted and the well-raked head and T.T. bars should render steering particularly safe. Rubber grips are fitted to the bars, and we think that this is a detail which should be universally copied, as they absorb the bulk of handle-bar vibration.

The tank is of the shape usually adopted on Dot machines, having slightly rounded sides, and is fitted with an Enots dome lubricator through which oil is automatically drawn to the engine. In addition to this, a hand pump is incorporated, so that extra lubricant may be forced through to the engine when desired. The wheels are fitted with 26×2 Dunlop tyres, and the rider is supported on a large Lycett pan saddle and neat aluminium footboards.

The large model Dot is an exceedingly neat looking machine, planned on well-tried lines. It is fitted with the 8 h.p. J.A.P. engine (85.5 × 85 mm. bore and stroke = 976 c.c.), and carries an E.I.C. magneto immediately before the front engine plates and above the silencer. The carburetter is an Amac. Transmission is by chains through a Sturmey-Archer three-speed gear box, with the new typ control and the well-known dry pla clutch. A metal case completely cove the front chain and clutch, and, extendin to the rear, covers the top of the fin driving chain and the upper half of th back wheel sprocket.

Sidecar Lugs Integral.

Sidecar lugs are built into the fram which is of neat design, low, and havin a wheelbase of sufficient length to secur comfortable running. A substantial an roomy carrier is fitted, into the sides c which large tool-cases are clipped. Broa mudguards are used, the front one havin deep valances, and aluminium footplate are included. Suspension at the front i carried out by a Saxon fork, which ha its spring well out of the way of mud an spray from the wheel, while the ride himself is insulated on an XL'All saddle

The finish of the machine is excellent being in dark red enamel, with a nicel rounded tank panelled in the same red o an aluminium grounnd, and carrying a Enots dome sight-feed lubricator.

R.A.C. AND BENZOLE.

IN view of the present high price c petrol and the general tendency t experiment with alternative fuels motorists will be glad to know that th Royal Automobile Club is taking a active part in the development of benzol At the forthcoming Motor Show a Olympia, London, the R.A.C. has place a portion of its stand (No. 8a) at th disposal of the National Benzole Associa tion, one of whose chemists will be i attendance to advise motorists, membe of the motor trade, and others intereste as to the immediate and future possibil ties of the new fuel.

A "BIG SINGLE" TWO-STROKE.

The Dunelt Motor Cycle—500 c.c. Engine with Truncated Piston.

The new Dunelt 500 c.c. two-stroke engine, which has a truncated piston giving a displacement on the under side of the piston of 770 c.c. Note its size compared with the foot rule alongside.

AT periodic intervals throughout the history of the motor cycle, the large single-cylinder two-stroke has made its appearance, but, in most cases, it is heard of no more. Each new engine, however, has shown some advance upon its predecessor; and, in view of the new discoveries concerning air-cooling which war experience afforded many engineers, it is not unreasonable to expect that all previous obstacles can be now overcome.

We know of at least three two-strokes with cylinders of 500 c.c. or over which are emerging from the experimental stages with every promise of success. One of these may be said to have passed this stage, and will be offered at Olympia as a serious proposition, intended for solo or sidecar work, at a popular price. This machine is the Dunelt, the production of Messrs. Dunsford and Elliott, Ltd., large Sheffield steel manufacturers, who have an experimental department in Birmingham.

For Cheap Production.

Often the view has been advanced that, with a moderately efficient two-stroke in the neighbourhood of 500 c.c., the main essential of the Ford type of motor cycle is secured; that with such a power unit it would be possible to produce a machine capable of taking the same place in the motor cycle world as that enjoyed by the famous American vehicle in the field of four-wheelers.

Messrs. Dunford and Elliott, recognising the enormous scope for a motor cycle suitable for solo or sidecar work, and which could be sold at a figure approximating to that of the lightweight, decided that only a two-stroke engine could make this possible; but, realising that the efficiency of the small conventional three-port engine would be difficult to obtain in a much larger size, it was decided to "borrow" one of the features of large two-stroke engines which are known to be satisfactory for marine and stationary purposes. This is the truncated piston—a type which is not exactly new to motor cycle practice, though this is the first time we have seen it embodied in a large single-cylinder engine which has been developed beyond the paper stage.

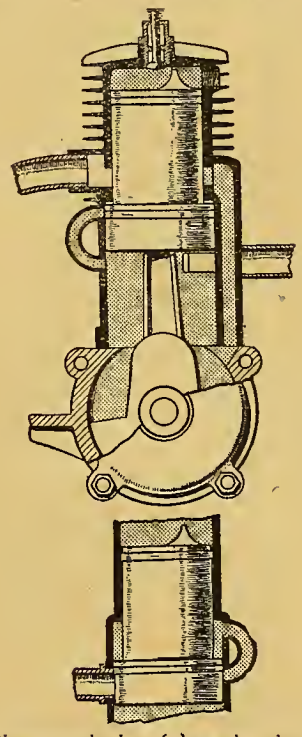
By the use of the two-diameter piston, it is possible to send through the transfer passage into the cylinder a charge greater than the capacity of the cylinder, while with the conventional two-stroke engine it is impossible to replace the dead gas by a volume equal to it. This will be appreciated readily when it is remembered that the displacement of a piston is only about 80% of the capacity of the cylinder, and dead gases must always be present in both two and four-stroke engines. For this reason, many engineers contend that the six-stroke engine promises greater efficiency. This, however, is by the way, and illustrates the fact that scavenging is desirable with a four-stroke engine, and almost essential in a two-stroke if anything but moderate efficiency is to be obtained.

A Double Diameter Piston.

In the Dunelt engine the scavenging is done by making the charge of new gas greater than the actual volume used, the displacement of the trunk piston being 770 c.c., while the working piston only displaces 500 c.c.

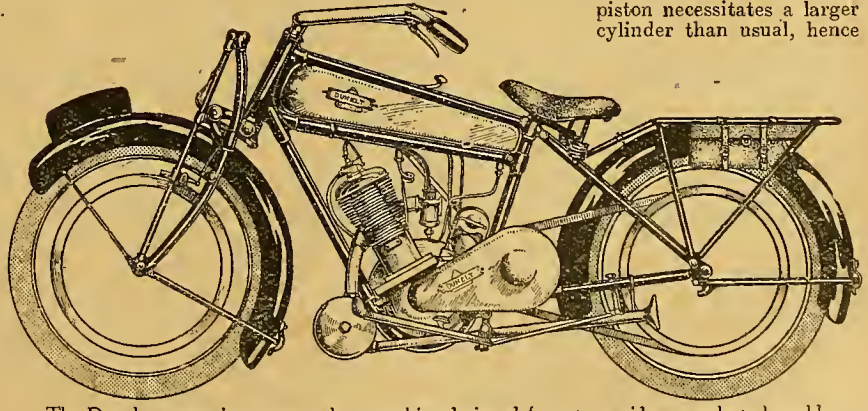
It may be argued that this will result in an extravagant waste of gas, but probably the overall efficiency will be quite proportionate to the more simple type of two-stroke, as, owing to the large quantity of dead gases always mixing with the fresh charge, an over-strong mixture is necessary to make the whole combustible.

In the Dunelt engine a better and "cleaner" mixture is retained in the cylinder, and approximates to the proportion of air and petrol vapour used in the four-stroke. We understand that 70 m.p.g. has been obtained with the Dunelt on the road, so its consumption cannot be said to be unduly heavy.



Diagrammatic view of the engine, showing the truncated piston. In addition to the initial displacement in the crank case, a charge is contained in the space above the trunk, which serves to cool the piston.

The use of a truncated piston necessitates a larger cylinder than usual, hence

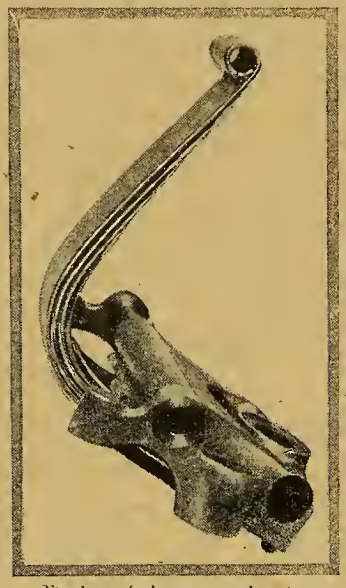


The Dunelt two-stroke motor cycle, a machine designed for solo or sidecar work, to be sold at a popular price.

A "Big Single" Two-stroke.

the Dunelt engine is quite an imposing unit. The bore and stroke of the working cylinder are 85 mm. and 88 mm. respectively, while the diameter of the trunk is 105 mm. With its large outside flywheel and massive cylinder the engine looks heavy, but, placed on the scales at our request, it was found to weigh but 65 lb., the average weight of a 3½ h.p. four-stroke engine.

From the diagrammatic view on page 509 it will be seen that, in addition to the crank case, there is an annular space above the piston trunk. This increases the compression in the crank case. The "cycle" is quite easy to follow with the aid of the diagram. On the up stroke of the piston a partial vacuum is created in the crank case, which is filled with new gas from the carburetter when the trunk exposes the intake. In the meantime, a small charge is being compressed in the annular space above the trunk, and immediately after the main charge has entered the crank case from the intake the up-going piston exposes a transfer port communicating with the annular space, thereby transferring this extra charge into the main volume of new gas. On descending, the trunk of the piston compresses the charge in the crank case while the annular space above the trunk is taking in its charge. Incidentally, it may be mentioned that this upper chamber is not required, but is one of those minor things which have to be endured for the sake of other advantages, but as the ports are shallow, in all probability the crank case space is not completely filled at high speeds, and the upper side of the pump is utilised to make good any partial vacuum at high speeds. It is the opinion of several internal combustion engine experts that the most important thing in engine design is to ensure that the gas reached the cylinder, which is an acknowledgment that this is a far more difficult undertaking than getting rid of the exhaust.



The front fork crown and spring.

Roller Bearing Big End.

In actual construction the engine is good, very substantial ball and phosphor-bronze bearings being used throughout, the gudgeon pin being ⅝in. diameter and the big end of the roller type. The drive is taken off the side opposite to the flywheel. The piston has two rings at the top and one on the trunk.

It will be seen from the illustration of the complete machine that, while unconventional, the design of the Dunelt is extremely clean. The engine is inclined towards the head and drives a neat two-speed gear of the expanding ring type by means of chains, the final drive being by belt. Embodied in the gear box is a kick-starter with enclosed mechanism.

The wheels are interchangeable, a brake rim being used on the front wheel exactly the same as that on the rear wheel. The tyres are 26in. × 2½in.

Domed mudguards 7in. across the beads, a two and a half gallon tank, and aluminium foot plates are included in the equipment, and altogether at the price at which the makers hope to market it, *i.e.*, about £70, the Dunelt will undoubtedly create a great deal of interest when it is exhibited at Olympia.

Flywheel side of the Dunelt engine, showing the wedge-shaped sliding member for magneto chain adjustment.

A New Friction-driven Cycle Car.

The Laurence-Jackson which is being Produced to Sell at £200. A J.A.P. Air-cooled Engine is Fitted.

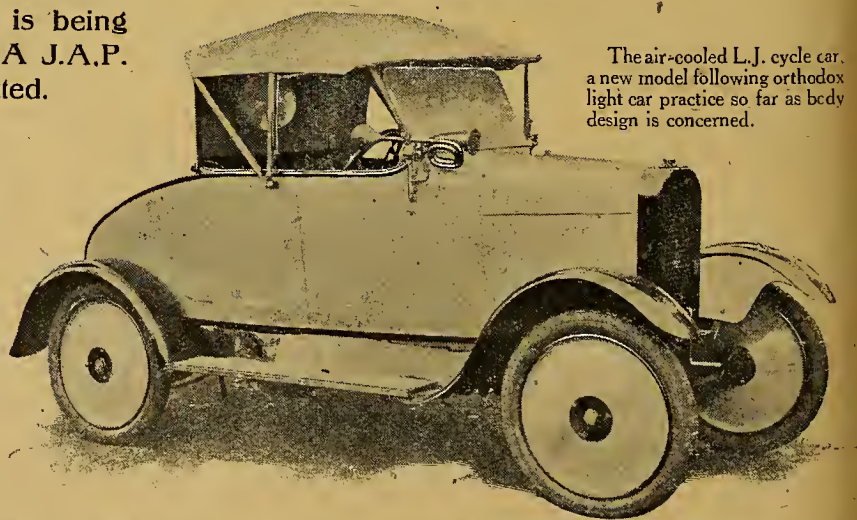
IT is doubtful whether the days of the early cycle car ever produced so large a number of vehicles of the "simple" type as are now being built as marketable propositions. In this connection, however, there is no comparison between the machines of 1911 and the present day, both on the point of appearance and of mechanical soundness.

We have dealt with many of these new machines, both of the three and four-wheeled types, which are likely to interest motor cyclists, and the latest we are able to illustrate is the Laurence-Jackson, made by a Wolverhampton firm.

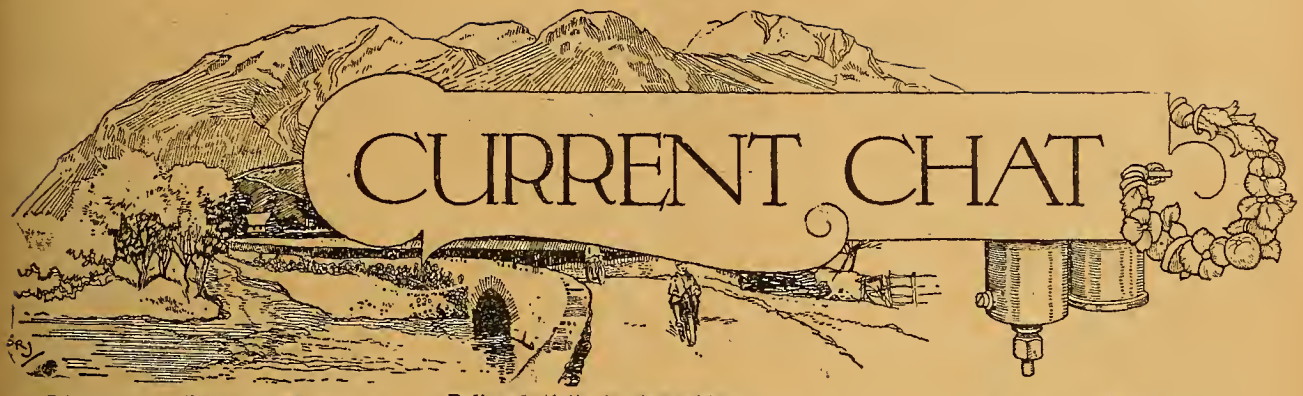
In this vehicle several points appear to have been considered from an aspect differing from the most general view. In the first place, a low sporting appearance has been deliberately sacrificed in order to seat the passengers fairly high above the road level.

The specification includes a pressed steel frame, transverse front and quarter-elliptic rear springs, 8 h.p. J.A.P. air or water-cooled engine, shaft and duplex chain transmission, and friction disc change speed, Lynton steel disc wheels, embodying detachable rims, internal expanding brakes, 700 × 80 mm. tyres, direct steering, and domed mudguards.

The car is being produced to sell at £200, and, we are told, orders are being accepted at this price.



The air-cooled L.J. cycle car, a new model following orthodox light car practice so far as body design is concerned.



Times to Light Lamps.

GREENWICH TIME.

Nov.	6th	4.54	p.m.
,,	8th	4.51	,,
,,	10th	4.48	,,
,,	12th	4.44	,,

British Motor Cycle in Canada.

The first shipment of Triumph motor cycles to reach Canada for some years arrived at Toronto recently.

Prices still Rising!

The following is a cutting from the *Birmingham Daily Mail:* "Allon, 1917, 2-speed, hand clutch, electrically equipped, excellent condition; £447 10s.; seen Saturday afternoon."

Police Trap.

We have received information of a police trap working in South End, Croydon.

There is a trap working near the village of Condorrat, on the main Glasgow-Edinburgh road, and about eleven miles from the former city.

Honours for Mr. Watson.

Mr. Duncan Watson, London manager of Messrs. the Harley-Davidson Motor Co., Ltd., who is mayor-elect for the borough of Marylebone, has just received news that he has been elected company director of the Harley-Davidson firm at Milwaukee.

Mr. Watson is an active motor cyclist, a keen and successful business man, both in the motor line and also in the electrical world, and a strenuous worker on behalf of the borough of Marylebone. He is also a member of the A.C.U. committee, and is taking an active interest both in that body and the corresponding organisation in America which is now being formed.

Cost of Motor Cycles.

At a recent meeting of the Management Committee of the Cycle and Motor Cycle Manufacturers' and Traders' Union it was concluded that there is no likelihood of a fall in to-day's price of motor cycles, the general tendency rather being in an upward direction. They state that since December the costs of raw material have risen again, and labour is even more expensive than it was at that time, and that it would, therefore, appear to be quite useless for intending purchasers to withhold their orders in the hope of prices falling.

Police Activity in Cambridge.

We are informed that the police in Cambridge and its vicinity are reporting all minor cases and technical offences—the magistrates being somewhat heavy in the extent of the fines inflicted. It therefore behoves motor cyclists in the district to exercise every care.

Garage Charges.

We understand that the Cambridge undergrads object to the garage charges now in vogue, and we are not surprised. Last summer the usual charge was 15s. for the term, but nearly 2,000 freshmen have matriculated this term, and the charge is raised to 30s., apparently by agreement throughout the town. A University term is about eight weeks, which means a charge of £9 15s. per annum.

THE SCOOTER IN INDIA.

Mr. C. J. Pool and his Autoped, the first vehicle of its kind seen in the streets of Bombay. It created great interest there, just as the scooter did when first ridden in the streets of London last year.

Special Features.

NEW MODELS.

OFFICIAL REPORT OF THE A.C.U. SIX DAYS TRIAL.

Swiss Prohibitions Withdrawn.

Some months ago it was announced in these columns that the Swiss Government had forbidden the use of motor vehicles, including motor cycles, in certain districts on Sundays between noon and 10 p.m., and total prohibition during certain days of the week on some of the mountain roads. We now have pleasure in stating that these prohibitions have been withdrawn.

A Motor Cycle Championship of France.

The well-known French motor cyclist, M. Colombel, has recently submitted to the Union Motocycliste de France a suggestion that each year a motor cycle champion of France should be selected. His idea is that the champion should be the motor cyclist who has gained the greatest number of points in the various competitions held throughout the year.

Our contemporary, *L'Auto*, says that the idea is well worth consideration, but it will be desirable for the U.M.F. to notify those competitions which should count for the championship.

Another "Race."

The *Edinburgh Evening Dispatch* of October 23rd announces that on Monday next the Edinburgh and District Motor Club has organised a *race* for the Palmer trophy. May we once again pray that the reporters of the lay press will desist from the practice of so misnaming reliability trials? Road races are illegal on the public roads of Great Britain, and, in consequence, no motor club arranges such events.

Trade Marks.

The President of the Board of Trade has appointed a committee to consider various points connected with the Merchandise Marks Act, such as the advisability of an extension or amendment in respect of the provisions relating to indications of origin, the utility of National Trade Marks or other "collective" marks, and the necessity for further international action for the prevention of false marking of goods.

Representatives of many trades, including the cycle and motor cycle industry, are on the committee. The secretary is Mr. M. F. Levey, the Patent Office, 25, Southampton Buildings, W.C.2.

A Coincidence.

By a strange coincidence, the total of marks awarded the winning B.S.A. team in the A.C.U. Six Days Trials was 557—the capacity in c.c. of the engine used.

A.C.U. Members at the Show.

Members of the Auto Cycle Union visiting the forthcoming motor cycle show to be held at Olympia, London, from November 24th to 29th, are invited to make use of the Princes' Rooms. There they will find full facilities for conducting correspondence and receiving letters, while there is also a lounge reserved for their convenience and provision for the serving of refreshments.

"The Autocar" Special Numbers

The Autocar, on sale to-morrow, and dated November 8th, forms a complete guide to the Olympia Automobile Exhibition, which opens its doors to-morrow at 10 a.m. The issue creates a new record in the annals of British motoring journals so far as completeness and bulk is concerned. Next week's issue of our parent journal, containing a full report of the car exhibits will be dated November 15th, and will be on sale at Olympia during the week.

Italian Ten Kilometre Races.

Eight competitors participated in record attempts on the road between Pignerol and Plossasco, Italy, on October 19th, the races being organised by the Turin Club. Davo (Della-Ferrara) succeeded in breaking the Italian ten kilometres record for 500 c.c. machines, made in 1913 by Maffeis. This stood at 6m. 4⅘s. The results of the ten kilometres trials are as follow:

500 c.c. CLASS.

	m.	s.
1. Dovo (Della-Ferrara)	5	42⅘
2. Borgotti (Fongri)	6	31⅘
3. Grignani (Fongri)	6	59⅘

Winner's speed in miles per hour=65¼.

1,000 c.c. CLASS.

1. Nozenzo (Della-Ferrara)	6	5⅕
2. Merio (Frera)	6	23⅘
3. Pezzaglia (Excelsior)	7	53

Winner's speed in miles per hour=61¼.

Old Timers' Dinner.

The annual Old Timers' Dinner—for which only members of the Fellowship of Old Time Cyclists are eligible—will take place at the Abercorn Rooms, Liverpool Street, E.C., on December 17th. E. H. Godbold, 8, Breams Buildings, E.C.4, is the hon. secretary.

THE MOTOR CYCLE

SPECIAL OLYMPIA SHOW NUMBERS.

Nov. 13th.—The feature of this issue will be a comprehensive survey of passenger machines.

Nov. 20th.—This issue will contain a forecast of the Exhibition, particulars of new models, also plan of the Show and list of exhibitors. This number will be on sale at the Show.

Nov. 27th.—Full Show report. This number will also be on sale at the Show.

Dec. 4th.—Review of sidecars, accessories, tyres, etc. Impressions of the Exhibition.

Stolen Motor Bicycles.

Information has been received of two motor cycles stolen from Hunter's Garage, Northland Drive, Scotstoun, Glasgow, during the night of October 16th-17th. The following are the particulars: Douglas, 2¾ h.p., W.D. model, 1916, but uncrated this year and in new condition, registered number GA 2137, engine No. 38,985, frame No. 39,999; Douglas, 2¾ h.p., 1914 (approximately), registered number EO 492, engine No. 10,110. Any information concerning these machines, and likely to lead to their recovery, should be sent to Mr. W. O'Brien, 116, Danes Drive, Scotstoun, Glasgow.

LIVERPOOL M.C. TRIAL.

THE judges' report and provisional results concerning the recent Reliance Cup Trial mentions that only twenty-five competitors succeeded in negotiating the watersplashes, which were 2ft. deep, and that it has been decided to rule out the five marks for failure in this section. The loss of marks at Sun Trevor (World's End), too, was ruled out. A bonus mark has been awarded to all who did not stop, making the maximum possible 102 instead of 100, and three competitors succeeded in gaining this number of marks. These were O. Wade (6 A.J.S. sc.), E. L. Boston (3½ Sunbeam), and R. R. Coes (7-9 Indian sc). Subject to final confirmation by the committee, the following are the results:

RELIANCE CHALLENGE CUP.—E. L. Boston (3½ Sunbeam).

MEAD MARTIN CUP.—O. Wade (6 A.J.S. sc.).

RELIANCE AMATEUR CHALLENGE CUP.—R. R. Coes (7-9 Indian sc.).

BUTTERWORTH TROPHY.—S. W. Phillpott (5 Brough sc.).

MOGRIDGE MEMORIAL TROPHY.—J. H. Green (7-9 Excelsior).

GOLD MEDALS.—V. L. Horsmann (4 Norton sc.), F. W. Giles (6 A.J.S. sc.), J. M. Parry Jones (5-6 Rover sc.), J. W. Wills (10 Henderson), G. E. Kuhn (2½ Levis), Geo. Brough (5 Brough), E. A. Colliver (7-9 Indian), A. W. Brittain (3½ Sunbeam), W. B. Gibb (2¾ Douglas), T. B. G. Vale (4 Norton), C. Collins (6 A.J.S. sc.), R. Charlesworth (5 Zenith), E. Williams (4 A.J.S.), G. S. Boston (8 Sunbeam sc.), P. V. Morris (3½ Sunbeam), J. A. Fox (4¼ B.S.A.), H. T. Williams (3½ Lea-Francis), J. A. Newman (3½ Sunbeam), N. H. Brown (7-9 Indian sc.), H. Marston (6 A.J.S. sc.), W. Heath (6 A.J.S. sc.), and H. Reed (8 Dot sc.).

SILVER MEDALS.—F. Marshall (3½ Sunbeam), W. Pattinson (4 Triumph), W. R. Haggas (8 New Imperial sc.), H. B. Denly (10 Morgan), S. Parker, Liverpool (10 Henderson), B. Kershaw (2¾ Venus), H. Poole (4 A.J.S.), A. W. Ratcliffe (5 Brough), M. Davies (3½ Sunbeam), H. Greaves (10 Morgan) S. Parker, Bolton (8 Enfield), and W. Ratcliffe (3½ Brough).

BRONZE MEDALS.—W. Edwards (4¼ B.S.A.), J. H. Place (8 Dot sc.), R. Arnold (6 A.J.S. sc.), N. Svanse (8 Morgan), R. H. W. Brown (6 A.J.S. sc.), W. Cottle (4¼ B.S.A.), T. Weaver (2¾ Verus), A. Moses (2¾ A.J.S.), R. E. Hugh (2½ Levis), G. Wray (3½ Triumph), L. T. Gilson (4-5 Zenith), T. Highfield (5 Brough), and R. Storey (7-9 Excelsior).

TEAM PRIZE (SILVER CUP).—A.J.S. Team No. I, 299 marks. W. Heath (96), F. W. Giles (101), and O. Wade (102)

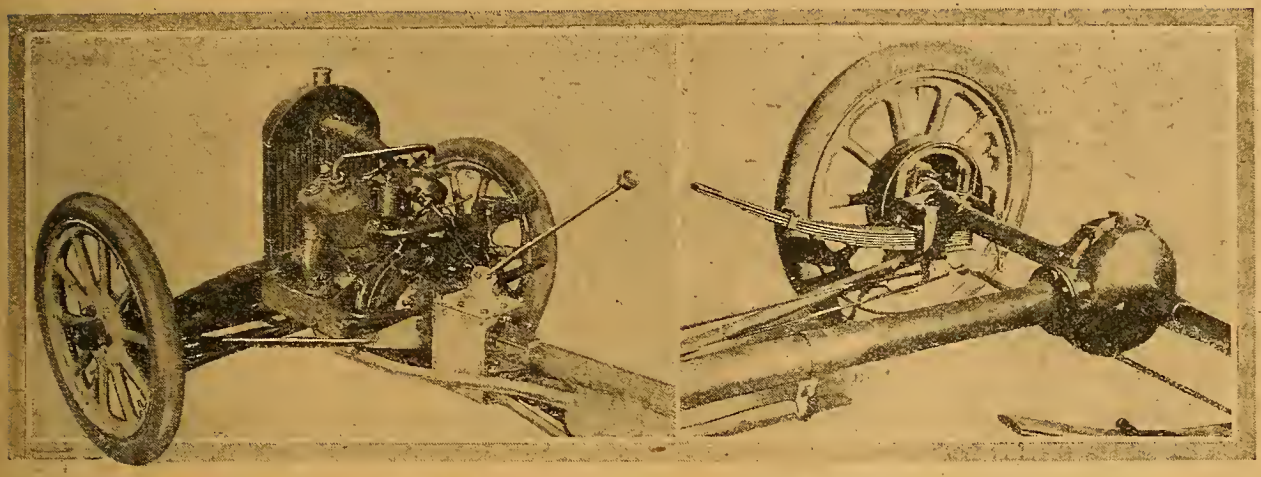
CLUB TEAM PRIZE (SILVER CUP).—Wolverhampton M.C.C., 294 marks. W. Heath (6 A.J.S. sc.), F. W. Giles (6 A.J.S sc.), and J. A. Newman (3½ Sunbeam).

A SIX DAYS TRIAL RECOLLECTION.

Interested spectators watching competitors in the C.D.T. on Panne Hill. The sidecar shown is the French G.L. On pages 515-518 will be found the official report of the trial.

THE EMSCOTE LIGHT CAR.

A Light Four-wheeler designed as a Competitor of the High-powered Sidecar.



The Emscote runabout, a light four-wheeler designed for competition with the powerful sidecar outfit. (Left) 8-10 h.p. water-cooled engine and three-speed gear box. (Right) The rear springing, brake, and differential.

FOR some time past there has been a good deal of talk about the possibility of constructing a sound four-wheeled light car which would be capable of competing, from a price point of view, with the more luxurious types of motor cycle and sidecar, and which would provide greater protection for the driver. A new firm, known as the Emscote Motor Company, Ltd., of Emscote, Warwick, has decided that such a feat is possible, and has devised a most ingenious little vehicle which, it is intended, shall be sold at a price but little higher than that of big sidecar outfits.

To accomplish a design which will provide both sound construction and cheap production facilities, it is, of course, necessary to eliminate all superfluous parts, and to reduce the amount of material to a strictly utilitarian basis. This has been cleverly carried out in the Emscote, and the first and most noticeable feature tending to this end is the entire absence of a frame in the ordinary sense of the word. The engine, gear box, propeller-shaft casing, and rear axle are bolted together so as to form a unit. This idea is, of course, not entirely novel, as it was carried out on the 6 h.p. Rover many years ago, but modern design has enabled unit construction to be used without detracting from the accessibility of vital parts. For instance, the engine unit can easily be removed from the small channel steel frame in which it is carried without disturbing any other part of the chassis.

Universal Joints Eliminated.

Directly behind the water-cooled V type engine lies a single disc dry-plate clutch, which transmits the power to a three-speed and reverse gear box, having a central change speed lever mounted on the top of the box and acting directly on the selector mechanism.

To the back of the gear box is bolted a stout tube enclosing the propeller-shaft and attached at its rear end to the bevel casing on the back axle. This form of construction obviates the necessity for any universal joints, and, consequently, saves both production cost and a certain number of wearing parts. The bevel casing is made in two pieces bolted together in the centre, and is fixed rigidly to tubular members enclosing the axle driving shafts. These tubular members carry on their outer ends spring pads and brake actuating brackets brazed to the tubes.

Brakes and Springing.

Both hand and foot brakes lie side by side in the rear wheel drums, and are enclosed by metal plates so as to prevent ingress of mud.

The unit is stayed by tie-rods from the rear axle to a point at the rear of the gear box, and the front axle is tied by radius rods in such a manner as to maintain wheel alignment in spite of the fact that any of the wheels can be raised to a very considerable height.

The springing is most ingenious, a single front transverse spring being used for the front axle. This spring is carried on a trunnion surrounding the starting handle bracket, which in turn is fixed to the channel steel engine frame, thus any of the four wheels may rise on striking an obstruction without interfering with steering or transmission, or imposing twisting strains on the chassis.

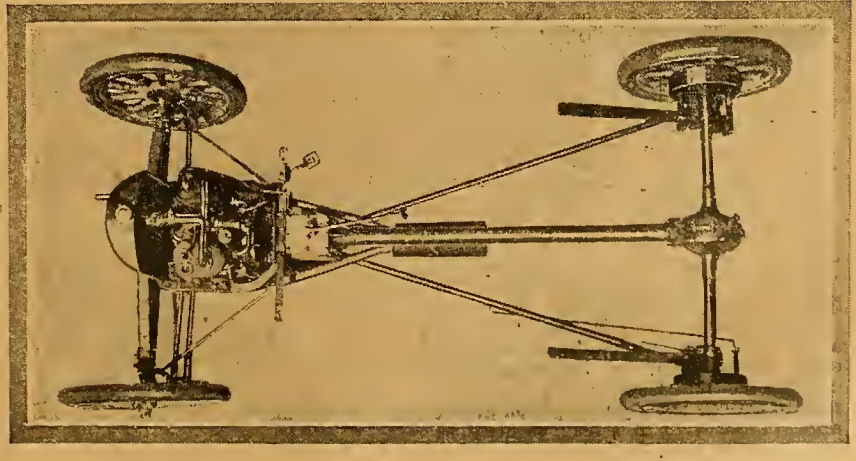
Just in front of the gear box lies a transverse spring to which the front end of the body is attached, the rear end resting on cantilever springs attached rigidly to the back axle, but free to move at the front end between rollers on the body. Steering is by rack and pinion.

On the preliminary model no differential has been fitted, but it has not yet been decided whether this feature shall be incorporated in the final design.

Detachable Wheels.

The wheelbase of the little machine is 6ft. 10in., and the track 4ft., and the specification includes 700 × 80 mm. tyres on detachable steel wheels, a spare wheel is included, and an electric lighting set.

It should be mentioned that undue strain on the gear box is obviated by the



Plan view of chassis. The body is bolted to the cross springs behind the engine, and is attached by slides to the cantilever rear springs.

The Emscote Light Car.—

fact that eight long bolts pass through the box to the propeller-shaft casing, and, in addition, there is a bracket at the front of the box which bolts to the engine cradle. Ball bearings are used throughout the construction of the gear box.

Rubber blocks are fitted between the radiator and the engine cradle, so as to relieve the radiator casing of vibration and undue strains, and a simple automatic carburetter is provided, by means of which easy starting is ensured without the necessity for either decompressor or exhaust valve lifter.

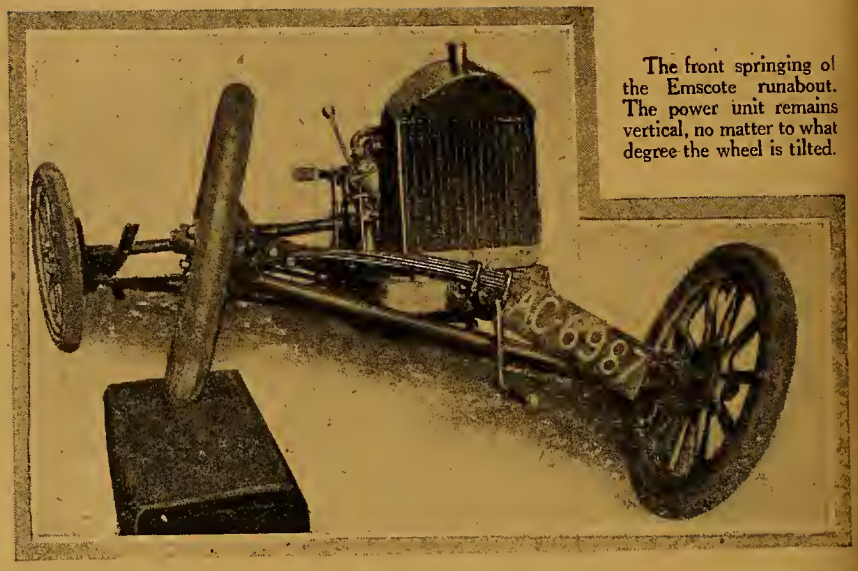
Quickly Detachable Body.

The construction of the complete vehicle is such that the body may be removed by merely undoing the steering and brake connections, the oil and petrol connections, and four body bolts.

We have examined the chassis, and find that it is thoroughly well carried out in all details. The weight of the complete machine is approximately 8 cwt., and it is intended that the selling price shall be in the neighbourhood of £230.

It is hoped that the Emscote will be in production shortly, but in the meantime, we are looking forward to a trial run on the experimental chassis, which is to take place in the near future.

It is hard to convey a correct impression of the size of the machine, but from the foregoing particulars and illustrations a fair idea may be obtained. In this respect the feature which most impressed us was that, though the chassis is remarkably small and neat, there was no cramping of passengers in the test body, and the lines of the complete machine are well proportioned. Of the many designs that have been put forward as competitors of the luxurious sidecar machine this is one of the most practical, though the question of price is all-important.

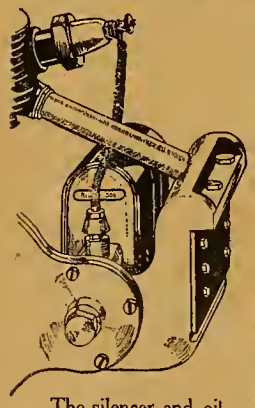


The front springing of the Emscote runabout. The power unit remains vertical, no matter to what degree the wheel is tilted.

THE SILVA SCOOTER.

A Design Embodying Modified Auto-wheel Power Unit

MESSRS. T. and T. Motors, Ltd., of 52a, Conduit Street, London, W.1, have recently departed from the manufacture of their principal product, the T. and T. engine oil, and have placed on the market a motor scooter possessing many interesting features.



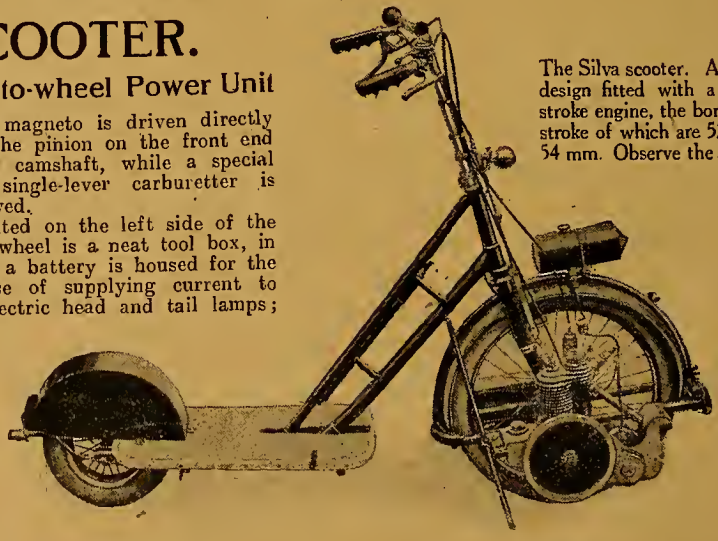
The silencer and oil sump cast integrally with crank case.

A small single cylinder engine, having a bore and stroke of 52.5 × 54 mm., is used, and although it is similar in design to that on the Auto-wheel, it has undergone no fewer than forty modifications to render it suitable for adaptation to the scooter.

An automatic inlet valve is fitted, whilst the exhaust valve is operated from a double-duty half-time layshaft located in front of the cylinder. The inner extremity of this shaft is provided with a chain sprocket, which, by means of a roller chain, drives a larger sprocket fitted to the front wheel, and gives a gear ratio of 8 to 1, but a larger pinion giving a gear ratio of 10 to 1 may be fitted as an extra when required for use in hilly districts.

The magneto is driven directly from the pinion on the front end of the camshaft, while a special S.U. single-lever carburetter is employed.

Located on the left side of the front wheel is a neat tool box, in which a battery is housed for the purpose of supplying current to the electric head and tail lamps; a switch is also fitted to the side of the tool box.



The Silva scooter. A clean design fitted with a four-stroke engine, the bore and stroke of which are 52·5 × 54 mm. Observe the stand

The neat front and rear lamps fitted to the Silva scooter.

The front mudguard is divided, and by releasing two fly nuts the front half may be removed, consequently reducing considerably the difficulty usually experienced when repairs to the front tyre have to be effected.

The rear wheel is equally accessible, a simple drop-out axle being employed. In view of the ridigity of the double girder frame, a special 300 × 60 mm. (12 × 2⅜in.) Palmer cord tyre is fitted to the rear wheel, which satisfactorily absorbs the smaller road shocks. The existing model, of which immediate delivery can be made, is priced at £55, and for the additional sum of £1 a seat will be supplied.

A.C.U. SIX DAYS TRIALS, 1919.

SUMMARISED OFFICIAL REPORT AND SCHEDULE OF RESULTS.

23 Gold Medals. 35 Silver Medals. 14 Bronze Medals. 9 No Awards. 29 Retire.

INTRODUCTION.

AS stewards of the meeting, we have pleasure in presenting the judges' report on, and the official results of, the Six Days Trials at Llandrindod Wells.

In view of certain protests that have been made, the following remarks may be of interest.

We have carefully examined the judges' report. We have also gone through the details and the markings with the judges personally, and we find no inaccuracies or mistakes in their calculations or procedure.

A. W. TORKINGTON, Chairman General Committee.
E. P. GREENHILL, Chairman Competitions Committee.
H. P. E. HARDINO, Chairman Touring Committee.

JUDGES' REPORT.

Before commenting on the results of the Auto Cycle Union Six Days Trials for 1919, the judges wish to draw attention to some of the new conditions under which this trial was held. The promoters considered that if the efficiency and design of motor cycles were to be really improved it would be necessary to apply a much more stringent examination test to each machine at the conclusion of the road test. Even though a machine had run the course, it might be seen, upon examination, that some parts would become unserviceable in a few hundred miles.

It is considered that a riding distance of 732 miles over a course chosen not only for the testing of springs and chassis, but of a nature which would demonstrate actual power maintenance, bears a not unfair comparison with the average life of a machine of perhaps three years, and is sufficient to show up at the final examination any serious defects in efficiency of design or manufacture. The trial was arranged under the following headings, the number of marks that might possibly be lost of a maximum of 200 being indicated after each test.

Reliability, 50; Acceleration and maintenance of efficiency, 20; Hill-climbing, 30; Brakes, 10; Mudguards, 10; Silence, 10; Condition at finish, 50.

Reliability.

Under the heading of Reliability the showing of the machines was distinctly good, and the proportion of riders unable to drive according to the scheduled rate of speed throughout the trial was not large.

Acceleration and Maintenance of Efficiency.

It should be noted that of the 466 marks lost by competitors who completed the trial in this combined test, 122 were for failure to drive at the maximum or minimum speeds set, *i.e.*, failures under "Acceleration." An analysis of the results indicates that the drivers of certain makes of motor cycle experienced difficulty in reaching the minimum speed set for the fast portion of the climb, whereas others in the same class exceeded it with ease.

Generally speaking, the maintenance of efficiency was excellent as regards the power output.

Hill-climbing.

Most motor cycles, by virtue of suitable gearing, are able to climb hills more or less satisfactorily, but the judges would point out that for an engine to run for any appreciable period suffering from incipient overheating, must eventually result in overstraining many parts. Even the larger machines have under these circumstances no reserve of power, and have made it very clear during the trial that efficient cooling has not yet been attained. The performance of the water-cooled motor cycles in the trial was very satisfactory; on the other hand, the state of many air-cooled engines after long climbs on low gear, as regards noise, smell, heat, and liability to knock, was not impressive.

Brakes.

The judges do not consider the brakes on most machines to be satisfactory, as they are not sufficient in many cases to ensure absolute safety. Observation of the machines in use was considered of secondary importance to the brake examination at the conclusion of the trial. It was intended to observe the descent of Fan Hill, not so much to judge of the holding power of the brakes as of their ease of operation and smoothness of working; unfortunately, a misplaced direction arrow caused a large number of competitors to miss this hill, and observations were therefore taken on another descent. A few cases were noticed when riders could not perfectly control their outfits without the assistance of the engine as a brake. This presupposes the transmission to be operative, which, apart from the aspect of safety, is not sufficient to conform with legal requirements. The hill finally selected was not so suitable for the purpose as the one originally chosen, and, moreover, competitors were not aware that the operation of their brakes was being observed. The few marks provisionally deducted on account of the road test of brakes have, therefore, been restored, and all penalties under the heading of "Brakes" have been made as a result of the examination of brakes at the conclusion of the trial.

Rear brakes were usually powerful, but are not always easy to renew, and were prone to excessive wear. The rods for operating should, as far as possible, be kept straight, and should not be

G. E. Stobart (5-6 James), followed by Jesse Baker (3½ Scott), on Machynlleth Hill in the Six Days Trials

Morris Isaac (3½ Rover) and a Triumph rider passing through Newtown on the third day of the Six Days Trial.

attached to pedals depending for their support upon a vulnerable portion of the footrests. The enclosed brakes of the Indian and A.B.C. machines are worthy of attention. The P. and M. motor cycles were fitted with a ratchet hand brake, and there is no apparent good reason why all passenger machines, at any rate, should not be provided with a ratchet brake instead of depending on engine compression, a stone, or the kerb, to prevent an unoccupied machine running away downhill.

Almost every machine having the ordinary stirrup pedal cycle front brakes (as distinct from brakes of the Lea-Francis and Chater-Lea type) finished with this brake in bad condition. On very many machines it was neither safe nor effective in operation, and such examples could not receive full marks under this heading. In very many cases these had become inoperative by the end of the trial, mainly owing to the design being such as to invite blocking and seizure of the operating mechanism by mud and grit. In some cases the total leverage available at the handle-bar to apply the brake was so small as to render it impossible to get more than an almost negligible braking effect. It is not desirable that it should be possible to lock a front wheel, but, short of this, a good braking effect is very necessary, especially for passenger machines.

Mudguards.

The mudguarding of machines has considerably improved, but in some cases the addition of detachable valances would appear to be desirable. The judge's decisions as to mudguards were based on their examination of the guards and the cleanliness of the machines at the end of the trial, in which they were to some extent guided by notes previously made by them as to the cleanliness of the drivers.

The judges deducted marks for obviously faulty protection, as many machines were cleaned *en route*, and could not, therefore, be entirely tested by observation. Mudguards varied greatly in condition, and the judges are of opinion that mudguard supports are not generally of sufficient strength at the points of attachment.

A good many cases occurred of sidecar mudguards being loose at the end of the trial.

Silence.

Under this heading, a simple apparatus was utilised to record the total air vibrations caused by the passing machines. The apparatus was placed in the position of an overtaken vehicle or pedestrian at a spot where the speed of the motor cycles and their distance from the apparatus was as nearly the same for all competitors as possible.

Most of the motor cycles were tested twice, and the judges individually noted the noisiness or otherwise, quite apart from the automatic and confirmatory tests.

Is is fully realised that differences of throttle opening and gear-changing may affect results, but these difficulties, together with that of machines passing together, are largely eliminated by holding the test primarily in a secret position and by its repetition.

Similar machines of the same make vary owing to timing and many other details just as their speed is never the same.

The general fitting of silencers is bad, and too often a simple push joint between exhaust pipe and silencer is used, resulting in much unnecessary noise and rattle. Little attempt has been made to silence mechanical and engine noises by enclosure (which is also a great preventive of wear), and it would, moreover, appear that the value of an expansion chamber terminating in a large pipe is not realised by many makers.

Final Examination.

As careful an examination as was possible in the time available was made. The condition of the machines before starting had been noted, and no attention was paid to the results of reported or otherwise obvious accidents. During examination the entrant was unknown to the judges, and attention was paid to the following points both before and after the road trial: General engine condition, including tappet side play, adjustment of gears, road wheel bearings, controls, frames, steering head, and general condition, excluding accessories.

Engines.

These in general show improvement, particularly as in this and other respects much difficulty is experienced by makers in obtaining suitable material. The cleanliness of the Matchless, Indian, Sunbeam, and A.J.S. power plants was creditable, but in far too many cases quite insufficient attention has been given to the retention of oil, leading to general dirtiness of machine and rider and wear to parts

Transmissions.

Transmissions show a decided advance in strength; but here again there are very few radical departures in design.

A general improvement in gear box condition was noted, though the adjustment of about 30% was found faulty.

Front Fork Bearings.

Adequate means for effectively lubricating the links, etc., of spring forks were frequently absent. Oil holes are utterly useless, and screw-down greasers appear to be the only proper solution.

Owing to lack of lubrication and lack of adequate bearing surfaces to take the lateral thrust (especially on sidecar combinations) of steering, wear rapidly develops, and a great deal of consequent sideplay was noticeable in many machines.

General Condition.

Chain cases seem better attached, but over the distance available in a trial of this nature no particular improvement is noticeable in the condition of enclosed over open chains. The springing of competing machines has not yet become at all general, and the constant complaint by riders of sore hands, etc., goes far to show that front springing is not yet quite satisfactory.

Where sidecar connections are made by lugs connected by bolts, the latter are practically without exception of the parallel type, which allows of no taking up of the play which invariably develops through road shocks, the bolt holes becoming elliptical and the bolts worn.

In some cases, crank-shaped tubular connections were used, and, as might be expected, these gave under severe road shocks, and tended to straighten out.

Controls.

These were weak and ill-fitted to withstand continuous rough usage and exposure. In particular, magneto controls and front brake connections were very frequently inoperative after four and a half days of fine weather driving.

A.C.U. Six Days Trials, 1919.—

Accessories.

Most of these were satisfactory, but speedometer drives are still very exposed. Lighting outfits are quite good, and the A.B.C. dynamo affords an excellent example of progress. Attention is directed to the exposed and vulnerable position of many magnetos. This is a particularly serious fault in the case of machines intended for colonial use.

Fuel Consumption.

On the run from Llandrindod Wells to Bala, of 68¾ miles over a trying course, petrol-driven sidecar machines covered approximately between 39 and 62 m.p.g. The three-wheeled cycle cars ran at about 43 m.p.g., and benzole-driven sidecar outfits at anything from 50 to 62 m.p.g.; that is to say, a distinctly better average than corresponding machines running on petrol. The figures in the next column were recorded.

No.	Machine.	M.P.G.	Fig. of Merit, Consumpti'n × Weight.	Fuel
115	Matchless sidecar	62·3	579	Benzole
98	Matchless sidecar	59	540	Benzole
85	Blackburne sidecar	55	530	Petrol
94	Indian sidecar ...	55	484	Petrol
101	Morgan Runabout	45	477	Petrol
66	Ariel sidecar	62	461	Benzole
112	Morgan Runabout	39	412	Petrol
105	Enfield sidecar ...	41	349	Petrol
89	Dot sidecar	39	329	Petrol

Special notice is merited by the general road performance of the following machines: B.S.A., Sunbeam, Scott, Triumph sc., Douglas sc., G.L. sc., Morgan, A.J.S., Levis, and Zenith.

Conclusions.

The judges hope to see much more attention given in the near future to the more completely enclosed machines with balanced multi-cylinder engines of all types and of medium weight. The performances of the small two-strokes were excellent, but the weights of machines in the trial were such that the true lightweight cannot be said to have competed.

This report has dealt largely with the faults of the motor cycle, nevertheless the trial has proved that in its most important qualities—speed, hill climbing, and maintenance of efficiency—the modern machine has reached another stage in its progress; the directions in which improvements should be sought have been indicated.

SPECIAL PRIZES.

TEAM PRIZE (Gold Medal presented by the A.C.U.): B.S.A. Team A (H.F. Edwards, 191 marks; J. L. Sealey, 175; and F. Turvey, jun., 191). Total marks, 557.

Order of Merit of Competing Teams: 2nd, Scott (539 marks); 3rd, Rover (536); 4th, Enfield (526); 5th, Sunbeam (521); 6th, Morgan (520); 7th, Blackburne (519); 8th, Matchless (507); 9th, Douglas (459); 10th, Triumph (445); 11th, James (439).

PRINCIPALITY PRIZE (Cup presented by Messrs. Tom Norton, Ltd., for the best performance by a Welsh competitor): M. Isaac, 3½ Rover.

FUEL PRIZES for best performances in each class on Benzole (presented by the National Benzole Association):

Class D.H. O. Wood, 3½ Scott (187 marks).
Class E. J. W. Wills, 6-7 Ariel (178).
Class G. F. E. Jones, 3½ Ariel sc. (152)
Class H. S. Sawer, 4 Norton sc. (169).
Class K. Rex Mundy, 8 Matchless sc. (186).

A Twenty-four Hour Ride of 540 Miles.

Italian Despatch Riders enter Sunbeams in an Italian Long-distance Trial.

ITALY, like France, is now taking an extraordinarily keen interest in motor cycle matters, and the trials that are organised in the former country rank in severity with those held here. A long distance run from Milan to Naples was held last week over vile roads, and constituted a twenty-four hours' trial, as the competitors took approximately that time to cover the distance—540 miles—between the two cities.

The finish, which ought to have been at Naples, was at the last moment brought back about fourteen miles to Caserta on account of the impossible state of the roads. Unluckily, this modification caused the two fastest riders to lose their way, and they arrived at Naples instead of Caserta, thus loosing the race. They were Maffeis, riding a Motosacoche, and De Leonardi (a despatch rider), on a Sunbeam.

Twenty-nine competitors started from Milan at 9.30 p.m. on Saturday, and, touching Bologna, Florence, and Rome, had to reach their destination, riding continually through the night and the best part of the next day, stopping only for the necessary replenishments at the various controls along the route.

The first 200 kilometres (125 miles), over good roads and under a beautifully moonlit sky, were covered at a speed of nearly 40 m.p.h. by all competitors, but after Bologna the crossing of the Apennines through the mist and over damp and slippery roads soon lowered the average considerably. Falls were frequent, and punctures numerous, so that at Florence already several competitors had fallen out and others were very late.

Pavè and Pot-holes.

When daylight came, however, everybody seemed to pick up courage, and the pace was as fast as the state of the roads permitted, and in all fifteen competitors arrived at Rome (375 miles) in the maximum time fixed. After this, however, came the worst part of the journey, the roads from Rome to Naples being absolutely vile. For the first twenty-five miles it is all *pavé* (and riders who have been in France know what that means), and afterwards a succession of pot-holes and mud inches deep (the weather having meantime changed to bad). This is due to the continual passage of carts having very narrow rims; these break up the surface, which is very friable. Two of the favourites, Acerboni (Frera) and Finzi (Rudge), had to give up on account of serious falls when almost in sight of the goal. Unluckily, as mentioned above, the two leaders lost their way when about six kilometres from the finish, and proceeded on to Naples, arriving at about nine o'clock, whereas the remainder of the competitors kept on the proper route, arriving in the following order:

		h.	m.	s.
1.	Girardi (2¾ Garelli) .. .. .. Average speed, 24 m.p.h.	21	56	2
2.	Pasquale Amerio (3½ Sunbeam) ..	22	5	7
3.	Giuseppe Russo (Sunbeam)	22	9	17
4.	Pierino Maggi (Motosacoche) ..	24	23	50
5.	Davide Gambini (2¾ Douglas) ..	26	42	10

These are the only survivors, plus the two that arrived at Naples in the following order, and covering 25 km. more.

	h.	m.	s.
Maffeis (Motosacoche)	22	23	0
De Leonardi (3½ Sunbeam)	22	59	0

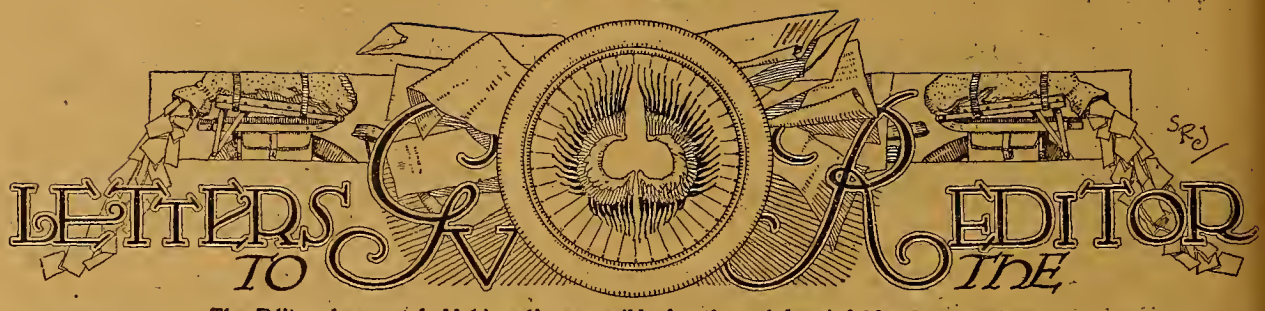
D.R.'s in the Trial.

The winner, Girardi, rode a 350 c.c. two-stroke Garelli, a new machine which has already competed successfully during the year, and will be put on the market in large quantities at the beginning of next year. It is a two-cylinder *monobloc*, side by side, placed transversely across the frame, 50 mm. bore and 89 mm. stroke to each cylinder. The mixture is taken into the left cylinder, and the burnt gases are exhausted through the right cylinder, as the cylinders are intercommunicating, and have one combustion chamber in common. The two pistons also work simultaneously on a single crankshaft. A great economy is claimed by this system, and it has certainly proved efficient. The gear box (two speeds) is incorporated in the crank case, as is the magneto, which is of special design and completely covered in, thus being protected entirely from water, mud, etc. This machine has a lovely purr, quite distinctive from others, and quite a good turn of speed. At the start, in the dark, it was easily recognised by its distinctive exhaust. The three Sunbeams were the only team to finish; they also made a splendid show, though one of them did not arrive at the official finishing point. Their riders are despatch riders who, owing to the sporting conduct of their officers, have been allowed to enter various competitions this year. Their first revelation was in the military trial, where they all finished amongst the first ten, classed with the same number of points. They received no official help from the makers of the machines they were riding (which, by the way, are Army property), and came through on their own resources. Truly a splendid performance. The small Douglas's performance is also remarkable, and the Motosacoche, to say the least, was very unlucky.

Board of Trade Removal.

The announcement is made that the offices of the Board of Trade are being removed immediately to Great George Street, where the new premises have been secured. The whole of the departments will gradually leave Whitehall Gardens as further accommodation becomes available.

At the start of the Milan-Naples long-distance trial. (1) Maffeis (Motosacoche); (2) Eng. Garelli, the designer of the winning machine; (3) Bonacossa, the president of the Italian A.C.U.; (4) Ettone Girardi, the winner.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters must be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

BUTSER HILL.

Sir,—I was interested to read in your issue of October 16th of the experiences of a correspondent, B. S. Nortsunbeam on Butser Hill, near Portsmouth. I have done a great deal of riding in that district, and can fully bear out his statements. My machine, which ascends hills like Birdlip and the Welsh Uplands without the least difficulty, invariably appears to lose power when ascending Butser. I can give no reasonable explanation at all, as I have examined the hill, and can find nothing out of the ordinary. Further experiences of your readers might prove interesting in this connection. J. G. SIMPSON LEE, Lt., R.M.

Sir,—The apparent loss of power ascending Butser used frequently to be commented on, and was by some ascribed to the wind in the cutting, but that could not always be the cause.

In 1905 and 1906 I could never get a single-geared sidecar machine up; even with l.p.a. on a 5-6 h.p. twin triette, it was the same. I used to stop and cool it on the railway bridge, but always had to resort to the tow rope, specially carried for Butser. After a long absence, in 1914 I tried it with a Ford. The road was up at the quarry, and we had to stop. Immediately getting into top, on restarting, I finished up close on 40 m.p.h.—no effort at all.

Again in January this year, on a new W.D. Douglas combination, the front exhaust pipe ran red hot on second near the top. Obviously, something upsets the cooling of an air-cooled engine. C. ROBERTS.

Sir,—In reply to "Nortsunbeam," page 436, in your issue of October 16th, *re* Butser Hill. I have been on this hill on an average once a fortnight for the last five years, riding several different makes of machines—"posh" and otherwise—and have never once noticed the apparent loss of power your correspondent speaks of, and I cannot understand "really fine machines" dropping down to 25-30 m.p.h. He states that he has made good ascents considering what others have been doing whenever he met them. Apparently, he is on that road at other times than I am, as my present machine will climb Butser at 50 m.p.h., with a passenger on the carrier, and that without "blinding" down the railway bridge, and there are plenty of machines on the road capable of doing the same. Possibly your correspondent overheats his engine before reaching the hills.

Farnborough. POWERPLUS.

A.B.C. PERFORMANCE AND A.C.U. TRIALS.

Sir,—May we correct a slight error which appeared in a paragraph in your issue of October 23rd, wherein you refer to an A.B.C. motor cycle at the Mont Ventoux hill-climb in France gaining six prizes in the 500 c.c, 750 c.c., and 1,000 c.c. classes?

The machine was certainly built to A.B.C. designs, but not in France, and it may interest your readers to know that, not only was it built in our own works, but was the actual machine that was ridden by Emerson through the A.C.U. Six Days Trials.

It was not our intention to complain at the loss of a medal, due to the ill-conceived and justly condemned "Consistent driving test," but recent references in the press attributable to the A.C.U., and suggesting that the public should form its opinions of certain machines according to the number of marks awarded in these trials, lead us to protest strongly against injustice being done where not incurred.

As a means of determining the "maintenance of efficiency" the "Consistent driving test" was a complete failure, and we imagine that the A.C.U. judges will have some difficulty in convincing the public that they are acting justly if they retain this in considering the final awards.

It would surely cost the A.C.U. nothing to acknowledge that an error of one second in a guessing competition cannot justly be compared in equal loss of marks with a delay of sixty seconds through trouble on the road; and an excellent indication of the insufficiency of this test is given in the performance of the A.B.C. machine in the French hill-climb above referred to.

This machine was returned to our works after the Six Days Trials on the Monday evening. It had the lighting set removed, was fitted with footrests, dropped handle-bars, and a lower gear, without any change in the engine, except the grinding in of the valves. On the Wednesday of the same week it was sent over to France without having been tried on the road for more than one mile, and as in France it proved its "maintenance of efficiency" in open competition, it will readily be seen that in the case of the A.B.C., as probably of a great many other machines, the result of the A.C.U. Six Days Trials, when judged by the number of marks awarded, is opposed to the truth, and is consequently, misleading to the public, besides being a direct injury to the trade.

Another point concerning the judging of these was the silencer test, mechanically recorded by Dr. Low. According to the results of these tests, the instrument is quite incapable of recording those sounds which most greatly affect the human ear, which, after all, is the only test concerning noise that we need bother about.

Some of us have observed the production of gramophone records, in which certain instruments (by no means the loud ones) are placed many yards further away from the receiving trumpet than others, in order to prevent the reproduction being completely distorted; and one is prompted to ask if the instrument used by Dr. Low was first verified by capable judges, and if the officials of the A.C.U. are satisfied that its accuracy was undeniable.

As judged by the awards, one can only conclude that the A.C.U. Trials were a failure, in that they defeat their own object, and as it must be of far more importance to manufacturers and the public to have the real truth stated than to the A.C.U. judges to "stick to their guns," could they not be induced to take a consensus of opinion amongst your readers concerning these two tests at least, and boldly acknowledge that their awards need modifying?

A.B.C. MOTORS, LTD.,
GRANVILLE BRADSHAW, Engineer.

SATURDAY TRIALS.

Sir,—As a motor cyclist of long standing—in fact, I have been riding since the days of the early Werners and Minervas—I want to air a little grievance.

How is it that all day trials and hill-climbs are held on Saturdays? I have no doubt there are hundreds of motor cyclists, like myself, who cannot possibly get away on Saturdays, but who would like to compete in competitions if they were held sometimes in the early part or middle of the week.

Perhaps in 1920 you could approach one or two of the leading clubs and see what the feeling is. I feel sure there are a lot of Birmingham riders who would enter for a run, say on the Wednesday closing day. TWO-STROKE.

Stratford-on-Avon.

SPEEDMAN'S WOBBLE.

Sir,—I asked a mathematical don at Oxford the explanation of speedman's wobble. He said it was a question of dynamics. Up to a certain rate the faster a motor cycle goes the steadier the equilibrium. Over that rate the equilibrium becomes unsteady, and any wobble there may be at the lower rate increases as the pace increases over what I may call the critical rate. This wobble is accentuated if the motor cycle goes over any bumps. The brake under these circumstances would act as a bump, and might throw the rider immediately. I have a 3½ h.p., and when riding it solo at a rate of 45 to 50 m.p.h. cannot feel any bumps on a moderately uneven road. I cannot get my motor cycle over 58 m.p.h , and at this rate engine vibration is so great I cannot take note of the effect of outside forces. MARTIN BEHRENS.

HONOUR TO WHOM HONOUR!

Sir,—One of the most useful features in your valuable paper is the column devoted to the experience, satisfactory and otherwise, of your readers. I should like to call attention to a smart piece of repair work. I recently purchased a sidecar from the Sandum Sidecar Co., which, owing to heavy mileage and bad roads, developed a weakness in the springs and also to the back axle. I communicated with the makers, and, placing the machine in their hands at 1 p.m. received it back with new springs and a straightened chassis at 6 p.m. same day, no charge being made, and the utmost courtesy was given me.

I have no interest in the firm beyond that of a satisfied customer. J. H. WHITE.

Sir,—I have read several letters in your most excellent paper referring to the great difficulty in getting repairs done to motor cycles, and I should like to give you my experience. Last week I took my machine to Messrs. Robertson, of Great Portland Street, to get a small but difficult repair done; and explained to them that it was most important that I should drive the machine home that night. The machine was ready for me four hours later, in spite of the fact that they had to send to several different places to get the part that was required. I have no connection whatever with Messrs. Robertson, but I should like other motor cyclists to know the name of at least one firm in the motor cycle repair trade who are out to do their best for anyone in difficulties. C. H. BLISS.

Sir,—I note from time to time letters are inserted in your valuable paper giving the names of reliable motor cycle agents, where repairs are quickly and satisfactorily carried out. I had the misfortune to smash both my footrests in a rather bad accident. I took my bicycle to Messrs. Henley and Son, Ocklynge Parade, Eastbourne—the repair was carried out in less than half an hour, and a most excellent job they made of it; the charge was 1s. At a later date they took my engine down and thoroughly cleaned and decarbonised it for 5s.

I understand that the proprietor was for several years a tester at the F.N. motor cycle works, and was in charge of an Army motor cycle repair shop in France during the war.

I have no interest in the business except as a satisfied customer. PERCY C. BIRD.

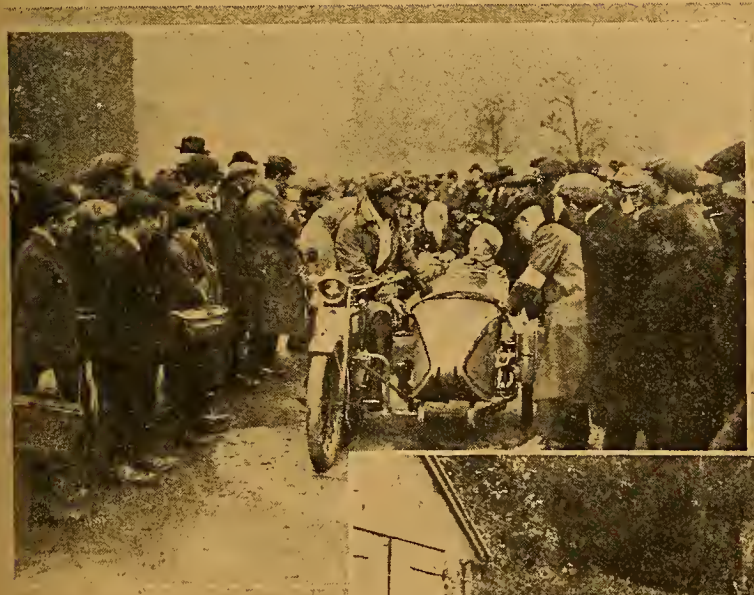
Sir,—I have been much interested in the correspondence which has been appearing in your columns with reference to good and bad treatment meted out to customers at various garages.

Perhaps a recent experience of mine may be of interest. On Sunday last I was driving an old pattern machine, when the front wheel cone worked loose, jamming the wheel. I was directed to Messrs. Campbell and Sercombe, of Approach Road, West Norwood, and they at once came to my assistance and freed the wheel sufficiently to allow of the machine being wheeled to their garage, where it was found that the threads were damaged. The machine was left for the night after some two hours' work, and next morning one of the partners drove me with the wheel to the makers' London depot, where a makeshift repair was effected. Eventually I proceeded on my way at about 4 p.m. on Monday, after various adjustments had been made and the time of the partners had been taken up for practically the whole day, in addition to the work on Sunday.

I was naturally prepared for a fairly stiff hill. Judge then of my astonishment when payment was emphatically declined, and all objection on my part swept aside.

I may say that both partners displayed a most workmanlike knowledge of motor cycles, and the muddle unfortunately associated with some garages was conspicuous by its absence. Usual disclaimer.

DOUGLAS SAMUEL.
Flying Officer, R.A.F.



LIVERPOOL M.C. ONE-DAY TRIAL.

(Top) J O. McLean (Harley-Davidson) at the start. Public interest in the competition was marked.

(Bottom) Competitors waiting to climb Sun Trevor Hill.

A detailed description of the trial was given in last week's issue.

Sir,—After many wearying attempts to obtain businesslike treatment from manufacturers, I have at last discovered an ideal firm. I refer to W. J. Green, Ltd., of Coventry, makers of Omega-Jap motors.

This summer my wife and I ordered machines from this firm. We have received every consideration. They never appeared to find it too much trouble to send lengthy and explicit replies to queries regarding mechanical details, and they made two considerable deviations from the specification at my request and without extra charge.

As they were unable to procure Hans Renold chains in time for delivery, they fitted another make, and afterwards sent us the Hans Renolds, informing us that we might retain the original ones as spares.

Last, but by no means least, this firm sends out all machines by passenger train and pays carriage.

Finally, I regard the Omega-Jap as the solo mount *par excellence* for the person who values reliability and clean design, combined with strength. I live amongst famous, or more correctly infamous, hills, and I find that these machines have a very real reserve of power. I have ridden most things from the 8 h.p. "hogbus" to the 1 h.p. auxiliary.

I add the usual disclaimer and enclose my card.

Barnstaple. VERBUM SAT SAPIENTI.

THE LIGHTING REGULATIONS.

Sir,—I must as a constant reader of your paper a cyclist and a motor cyclist emphatically protest against your leading article on Lighting regulations. The toleration you speak of is a toleration of motorists only a minority and always will be as far as cyclists are concerned; who have the prior right if our boasted brag of the majority ruling counts for anything. Accidents to cyclists and pedestrians are caused by excessive speed in 99% of cases as you know quite well; and you must be aware that no country in the wide world passes them off in the scandalous manner as is done here; life being more sacred with them than with us; you are decidedly wrong when you say that a pedestrian is more easily seen than a cyclist; he is certainly not as he carries no head lamp; and it is not his business to jump into the ditch every time he sees side lights. Both motor cars and motor can run slowly on dark nights; they all have speed gears and it is simply a matter of economy only with them. How many motorists will throw in a second speed turning a corner in the dark—Only few If motors are constructed as to be untractable; it is up to the makers to make them so

Personally riding slowly at nights I can see cyclists and pedestrians with all safety to them, and I am an elderly man.

The villany of the whole concern; a man going to his work in early mornings to mess about with two lamps in the dark and cold; and ditto at night; what for? to convenience motorists, who in 'nine' out of ten cases are not tied to five minutes. No Mr Editor—when the public not your idea of such, decides on rear lights and is willing to submit; then let rear lights stand. ISAAC BARTU.

Cork.

[We think that our correspondent misrepresents us; but, on the principle of giving a hearing to both sides, we print his letter exactly as received.—ED.]

Sir,—With regard to the question of rear lighting at present under discussion, and the somewhat acrimonious correspondence appearing in the press (not in *The Motor Cycle*), will you favour me with space to air my views?

I have been a cyclist for some thirty years, and, therefore, claim to have some knowledge of matters cycling, my experience embracing twenty-five years as a pedal cyclist and later as a motorist.

In the first place, there is evident in many of the articles I have read, both letters and "leaders," a striking absence of that spirit of tolerance and fairplay on which we Britishers have been wont to pride ourselves. Although now a confirmed motor cyclist, after a protracted experience of the delights thereof, I find it difficult to associate myself with the views expressed by some of my brothers of the petrol engine. Their arguments for enforcing the use of the rear light on cyclists are, surely, of the "boomerang" order. To say that a cyclist must carry such light in order that his presence may be thereby known to the motorist is certainly one of the most absurd grounds that could possibly be put forward. In addition to cyclists, one will occasionally come across pedestrians, cattle, stray horses, broken down carts, parcels dropped from vehicles (my own experience), bricks, and numerous other sources of possible trouble. What form of danger signal do the enthusiasts of the rear light propose for these impedimenta? Is it to be wondered at that the non-motoring public are forced to the conclusion that the whole agitation is the outcome of the unfortunate craze for speed amongst the more reckless members of our fraternity? I have, myself, on numerous occasions escaped by a hair's breadth being smashed up by passing motorists at night—in spite of my rear lamp! I say to these selfish madcaps that no one has any right to be travelling at night at such a speed that he cannot discern any other traffic in time to avoid it! The arguments, or rather statements, put forward in some quarters on behalf of the rear lamp are such as to make one wonder at the mentality of the writers; witness the piffle recently published in one of the motoring papers, where it is stated that "the cyclist is always wanting to dictate to the motorist," "he pays nothing for the use of the roads," etc. As we say in the law, "No case, abuse the other side."

For myself, if I were still a pedal cyclist, I should carry a rear lamp, not because I considered it necessary to indicate my presence to the reasonable motorist, but simply and solely as some protection (for what it is worth) against the scorching road-hog. At the same time, I would resist by every means in my power the attempt to *enforce* its use upon cyclists. Recent events have proved its utter failure as a reliable safeguard against accidents. SIVEL.

London, N.

COMPRESSION RELEASE V. EXHAUST VALVE LIFTER

Sir,—I was glad to see this question raised by Mr. Maggs. As a matter of fact, the idea of using a compression release valve instead of an exhaust lifter was put into practice by me early in 1917, and the same valve has been in constant use since then on different machines. The body of the valve was made out of an old sparking plug and the valve out of a Douglas valve. It is placed in the centre of the cylinder head instead of the compression tap, and connected up to the exhaust lifter lever by Bowden wire. After an extended trial of over two years I have come to the conclusion that an exhaust valve lifter is entirely unnecessary, as the release valve has the following uses:

(1.) For injecting petrol.

(2.) For cooling the engine when coasting down hills, as it sucks in cold air directly from the atmosphere.

(3.) As an engine brake when partly open.

(4.) As a dog frightener, being far more effective than making a hissing noise with the mouth.

All the aforementioned uses are, I consider, advantages over the exhaust lifter. Other points in favour of the release valve are that there is practically no strain on the Bowden wire, and it is commercially cheaper to fit than the exhaust lift mechanism and compression tap combined.

C. S. BURNEY.

SUMMARY OF CORRESPONDENCE.

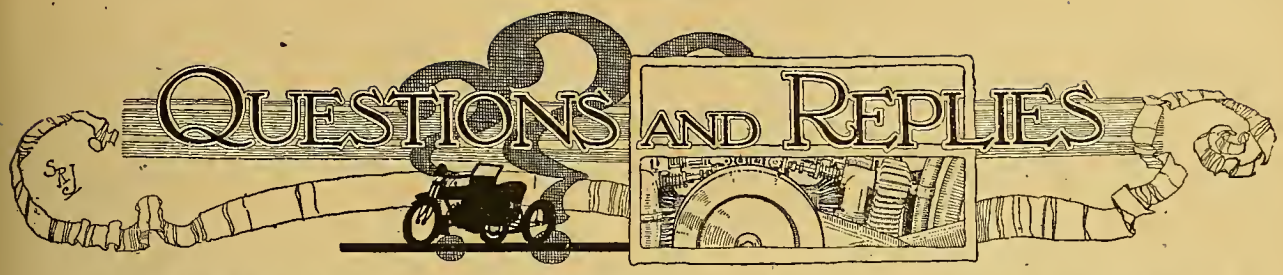
Mr. R. Griffiths, of Saundersfoot, Pembrokeshire, writes to say that he was refused admission to Jones's Garage, Swansea, as motor cycles and sidecars are not garaged there.

BOOKS AND MAPS FOR MOTOR CYCLISTS.

Issued in conjunction with "*The Motor Cycle.*"

	Price net.	By post.
"MOTOR CYCLES AND HOW TO MANAGE THEM." The standard handbook on the motor cycle—its care and management. Twentieth Edition. 286 pages. 400 illustrations	2/6	2/10
"HINTS AND TIPS FOR MOTOR CYCLISTS." Containing over 400 useful "wrinkles" and helpful hints in regard to motor cycles. Sixth Edition. (Second Reprint.)	2/-	/9
"TRACING MOTOR CYCLE TROUBLES." A reliable system for tracing motor cycle faults and of remedying any trouble when found. Fourth Edition	2/-	/3
"THE MOTOR CYCLE" ROAD MAPS. England and Wales. Scotland. London (showing roads into and out of London and avoiding London). Mounted on linen. Set of three, complete in case	4/6	4/10

Obtainable by post (remittance with order) from ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4, or of leading Booksellers and Railway Bookstalls.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Fitting a Speed Gear.

I have a 1912 A.S.L. 4 h.p. Precision engined motor cycle. Can you please tell me what kind of speed gear or variable pulley gear would be suitable for fitting to the machine for sidecar work? —T.S.

We do not know of any speed gear other than one for the engine-shaft that can be very readily fitted to your machine. A Philipson pulley would be satisfactory or one of the N.S.U. type two-speed gears now being manufactured in this country.

Colonial Prospects.

I am contemplating making a trip to South Africa, Australia, or New Zealand, with the object of starting a garage, and should like your opinion on the matter. Would you say the prospects were good for engineers, and which country would you prefer for opening business?—L.W.H.

From information we receive from time to time, the prospects of the motor cycle industry are excellent in all the colonies you name, but especially so in New Zealand and South Africa. We think you will find the greatest scope in the Antipodes.

Pilfered Accessories.

I met with an accident to my motor cycle and had to leave it at a garage for repair. Later, I discovered that all my tools were missing. Before leaving the machine, I pointed out to the proprietor that all my tools were in the sidecar, and he said that they would be quite all right. Now he refuses to replace them, but is quite willing to let me have them at cost price. Can I make him replace them? I might state that my wife was with me at the time. Also he informs me that I ought to have had them checked. —V.M.

Under the circumstances you describe, there appears to have been some laxity in handing over the machine and its accessories to the garage proprietor, and we fear that you are rather in his hands. If you can provide witnesses, however, who will bear out your statement that the tools were in the sidecar when you left the machine, and can also prove negligence on his part in storing your machine, there is no doubt you could enforce their return. At the same time, the value of the articles involved is so small that it would not be worth while incurring a legal action.

Fitting Lighting Dynamo

As I am not anxious to make use of a magneto as a light generator, I have a dynamo (weight 2 lb.) which could be fitted to my machine. The speed of the dynamo must be over 3,000 r.p.m., but the maximum voltage is automatically controlled. Do you think a pulley could be attached to the engine-shaft (3½ h.p. Rudge Multi) by cutting a hole in the timing cover? If so, please give necessary details for the work, so as to avoid putting the pedals out of action. What is the engine speed on a 3½ to 1 gear at about 25 m.p.h.?—A.U.

In adapting the lighting dynamo to your engine it would be necessary to gear it from the engine-shaft with a 3 to 1 ratio. It would be very difficult to drive it from the Rudge engine without interfering with the starting mechanism. The engine speed on a 3½ to 1 gear at 25 m.p.h. is approximately 1,200 r.p.m.

Gearing and Carburation.

Would you be kind enough to give me information on the following: (1.) My 1919 4 h.p. Triumph is geared 5 to 1 top. I ride solo, and wish to raise the gear to 4, or even 3½, to 1, if possible. The present engine sprocket has fifteen teeth, and as the chain case can be removed over the sprocket without sliding forward, I think it will give sufficient clearance for a larger sprocket. Will you tell me the size of sprocket required to give the gears before-mentioned, and where I can obtain them? (2.) My standard Triumph carburetter (Pratt's No. 1 petrol) averages 80 to 90 m.p.g. I am told that either of the following will give lower consumption and better running: *(a)* Bowden extra air valve. *(b)* Smaller jet. Your opinion and advice will greatly oblige. I have never had occasion to use the air lever, except for very slow turning over.—H.W.L.

(1.) We do not recommend so high a gear as 3½ to 1. Probably a seventeen-tooth sprocket (4.4 to 1) would raise the gear sufficiently for your requirements. The Triumph Co. will supply. (2.) We should not recommend the fitting of an extra air valve. A smaller jet might effect some economy in petrol consumption, but if you obtain 90 m.p.g. this is quite satisfactory. The use of benzole would improve the consumption by about 15%. The air lever on the Triumph carburetter is very seldom used.

Stove Enamelling.

(1.) Is it possible to install a small stove at home for enamelling purposes? (2.) Whether gas or coal required, and at what temperatures? (3.) Is a specially prepared enamel used?—G.G.M.

(1.) Stove enamelling can be done on quite a small scale. (2.) Enamelling stoves are usually gas heated. The temperature required depends upon the colour of the enamel used. The greatest heat is necessary in stoving black—about 300° F. (3.) Special enamel is required; it may be obtained, as also the apparatus necessary, from any wholesale cycle factor.

Acetylene as Fuel.

Has anyone ever invented any article for driving a motor cycle or car on carbide instead of petrol, and, if so, has it been tried, and with what success?—S.N.R.

Internal combustion engines have frequently been run on acetylene gas. Some considerable danger attends its use in an engine primarily designed for the consumption of petrol. In any case, the use of acetylene as a motor fuel has been found to result in uncontrollability and harsh running. A description of a Swiss patent on the lines in which you are interested appeared in the issue of *The Motor Cycle* dated October 9th, 1919.

Retarding Ignition.

If there is an appreciable loss when retarding the spark, can you tell me the reason why motor cycle manufacturers never give the matter any attention, but still continue to fit the same principle of magneto year after year, when obviously they are losing a certain amount of power?—H.F.

The reason for the adherence of manufacturers to the present type of magneto is largely one of convenience. At moderately high speeds the loss of sparking efficiency, due to retarding, is not so great as to cause any practical disadvantage. Magnetos have been made which give maximum efficiency over a full range of advance and retard, but they are not so simple to manufacture, and the design introduces other weaknesses. This quality is usually obtained by rotating the field magnets round the armature in place of moving the contact breaker cams. The polar inductor type of magneto, such as the American Dixie, also has maximum sparking efficiency through its full range.

READERS' REPLIES.

N.S.U. Gear Trouble.

With reference to the reply to "H.F." concerning N.S.U. gear trouble. I had the same this summer with one of these gears, and cured it by fitting a small washer over the stud at the bottom of the rotating rod, thus giving the extra pressure necessitated by the wear on the inclined planes.—H. WEBSTER.

Removing Indian Cylinders.

For the information of "C.L.W.," who wishes to dismantle Indian cylinders, he should remove the head and then unscrew three of the studs out of the crank case; the cylinder can be removed quite easily. Being an Indian rider, I can assure "C.L.W." that the heating of the crank case is nothing to worry about; this makes no difference to the running of the engine, and is, I believe, due to conduction.—W. CLEMENTS.

Two-stroke Triumph Gear Box.

Re the enquiry from "H.E.G.M.," in *The Motor Cycle* dated October 16th, in connection with some apparent metallic substance in the grease of his Triumph gear box. Perhaps he may be mistaken, as I was. I bought a 1919 Triumph second-hand, and, when about to fill the gear box, was greatly disturbed to find similar particles in the grease. I therefore took the gear box down and found everything in order and no sign of worn teeth. Upon a close examination I discovered the "metallic substance" was only graphite, which forms part of the grease, and, of course, is not in any way injurious, but quite the reverse. I should advise "H.E.G.M." carefully to make sure whether it is metal before going to the expense of new parts.—E.J.F.

RECOMMENDED ROUTES.

DURHAM TO IRLAM.—J.H.

Durham, Darlington, Scotch Corner, Leeming Bar, Ripon, Ripley, Blubberhouses, Bolton Bridge, Skipton, Gisburn, Clitheroe, Whatley, Accrington, Haslingden, Holcombe, Bolton, Walkden, Patricroft, Irlam.

BIRMINGHAM TO CATERHAM.—T.A.B.

Birmingham, Coventry, Daventry, Dunstable, St. Albans, Watford, Rickmansworth, Denham, Uxbridge, Colnbrook, Staines, Kingston, Worcester Park, Sutton, Purley, Caterham. Approximately 110 miles.

NEWCASTLE-UNDER-LYME TO NEWCASTLE-ON-TYNE.—J.F.T.

Newcastle-under-Lyme, Leek, Buxton, Tideswell, Totley, Sheffield, Barnsley, Cudworth, Hemsworth, Pontefract, Ferrybridge, Aberford, Wetherby, Boroughbridge, Thirsk, Yalm, Stockton, Durham, Chester-le-Street, Newcastle-upon-Tyne.

WORCESTER TO CLACTON-ON-SEA.—G.W.R.

Worcester, Evesham, Broadway, Moreton-in-the-Marsh, Chipping Norton, Deddington, Aynho, Bicester, Aylesbury, Tring, Berkhampsted, Boxmoor Station, St. Albans, Hatfield, Hertford, Bishop's Stortford, Great Dunmow, Braintree, Colchester, Clacton-on-Sea.

F.R.S. in Australia.

We learn that F.R.S. lamps are now represented in Australia by Finlay Bros., Barb Cycle Works, 322-324, Elizabeth Street, Melbourne.

Leather Transmission Belting.

The business of W. Pollin, Silverhill, Hastings, has now been reorganised as W. Pollin and Son, and will be carried on at Hollington, St. Leonards-on-Sea, specialising on leather and balata belts.

A Six Days Echo.

One of the few machines to make a maximum road performance in the A.C.U. Six Days Trial was the 8 h.p. Clyno outfit. It was lubricated with Vacuum BB oil, and the engine never faltered on any hill.

Autoped Scooter Deliveries.

Messrs. A. W. Gamage, Ltd., Holborn, London, E.C., inform us that they are now able to give delivery from stock of the Autoped motor scooter. The Autoped figured in the first scooter trials organised by *The Motor Cycle* during the summer, and was first described in *The Motor Cycle* of January 25th, 1917.

Enfield Balance Sheet.

The directors of the Enfield Cycle Co. recommend a further dividend of £7 per cent. per annum on the A preference shares for the half year, and 12½% on the B preference and ordinary shares for the twelve months. In view of the considerable increase of the company's business, a further issue of 50,000 ordinary £1 shares is proposed; these will be offered to present shareholders only.

Bates Tyres in the North.

Increasing popularity of Bates tyres and other goods manufactured by W. and A. Bates, Ltd., St. Mary's Mills, Leicester, has led to the necessity of opening a wholesale distributing depôt in Manchester, the address being St. Mary's Buildings, Quay Street. All the Lancashire, Cheshire, Yorkshire, and North Wales business of the firm will be dealt with from the Manchester house.

The South African Tourist Trophy Race.

A special commemorative prize—a gold medal with diamond centre—was awarded to J. P. Booth (Triumph Junior) for his wonderful performance in the South African Johannesburg-Durban race. Despite the small capacity of his engine, he finished fifth over the 397 miles course, with an average speed over the full distance of over 25 m.p.h. C. H. Young (4 Triumph), who finished second, was the fastest of the single-cylinders, averaging 36.3 m.p.h., as against 36.8 m.p.h. by the 7 h.p. Harley-Davidson, which, ridden by R. Blackburn, made fastest time in the race.

The Bowden Brake Co., Ltd.

In the directors' report of the Bowden Brake Co., Ltd., it is stated that a dividend of 15% is to be paid on participating preference shares, and also on the ordinary shares, both free of income tax.

British Tyres in Spain.

We learn that in the twelve hours motor cycle race, held recently in Spain, the winners in all classes were running on Dunlop tyres. This success of British goods is specially gratifying at a time when the export trade is so vital a factor in the country's interests.

Address Wanted.

The Licences and General Insurance Co., Ltd., 24, Moorgate Street, London, E.C.2, inform us that one of our readers, Mr. H. A. Connell, has written to them, but has omitted to send his address. On hearing further from him, the company will immediately send a reply to his communication.

Premises Wanted.

A well-known competition rider is offering £10 reward to anyone who will find him suitable premises. He requires a showroom and repair shops in the West End, South, or South-West of London, but a suitable shop in the provinces might meet the case. We shall be pleased to forward letters.

Dissolved Acetylene Cylinders.

Many of our readers are anxious to try dissolved acetylene as a means of illumination. These will be interested to hear that Messrs. Vivian Hardie and Lane, Ltd., 24, Woodstock Street, Bond Street, London, W.1, have the D.A. cylinders and all the necessary fittings in stock.

Metro-Tyler Hints and Tips.

Any rider of a 1919 Metro-Tyler may have a copy of "Metro-Tyler Hints and Tips to Users" on quoting the number of his engine, and communicating with the Tyler Apparatus Co., Ltd., Bannister Road, Kilburn Lane, London, N.W.10. The leaflet published gives four pages of useful hints, which should be of great value to users of this popular lightweight.

Sunbeams in Italy.

Sunbeams have been extraordinarily successful in a recent motor cycle race in the land of sunshine. In the Milan-Naples event, extending over 526 miles, the only team to arrive complete was the Sunbeam, which was composed of three motor cycles which had been two years on military service. They arrived second, third, and sixth among thirty competitors, but nine minutes after the first arrival.

Activity in Bournemouth.

Messrs. Perrins, of Aldwych, London, recognising the scope for motor engineering, and also the lack of garaging space, in the town of Bournemouth, have opened a branch in Sea Road, Boscombe. Among the agencies secured are those for the Skootamota, Norton, and for Monobloc cars. It may interest some to learn that the directors of the company are Capt. M. Perrin, A.M.I.C.E., Capt. G. E. Thomas, Capt. H. S. Keightley (all late of the R.A.F.), and Mr. T. B. Woodward.

MOTOR CYCLES FOR SALE.

A.J.S.

A.J.S. 6h.p. Combination, fully fitted, military model, for rough work, late 1918 model, splendid condition, spare wheel (interchangeable), with spares; genuine; £155, or offer.—Archbold, 79, Banastre St., Liverpool. [X7365

1919 A.J.S. 6h.p. Combination, interchangeable wheels and spare, wind screen, hood and side screen, all in perfect order, delivered last September; owner bought car; £180.—Blackburne Williams, Ty Mawr, Abergele. [X7465

A.J.S. 6h.p. and Coachbuilt Sidecar, 1913-14 model, 3-speed, countershaft, clutch, all chain drive, kick start, lamps complete, just been overhauled, excellent condition, little used during war; inspection invited; £98.—Apply, 39, Britannia Sq., Worcester. [1935

1914-15 6h.p. A.J.S. Combination, in splendid condition, all spares, tyre, tube, lamps, etc., canoelet C.B. sidecar, unscratched, with spring shock absorber, and special upholstering; £110, a bargain; solo machine in part exchange considered.—1, St. Patrick's Houses, St. Paul's Rd., Peterborough. [X7288

Alldays.

ALLON. — Caffyns, Ltd., Eastbourne, for delivery shortly. [0063

ALLON.—Guaranteed early delivery latest 1920 models.—Parker's, Deansgate, Manchester, Bradshawgate, Bolton. [X7422

ALLDAYS Allon, 2-speed, all accessories, recently overhauled, engine perfect, all in exceptionally good condition; £48.—116, Askew Rd., Shepherd's Bush, W. [1659

ALLDAYS Matchless, 1914-15, 4h.p., variable gear, Bosch, Senspray, lamps, horn, speedometer, spares, perfect condition; bargain, £50.—30, Chandos Rd., Cricklewood, N.W.2. [1557

JONES' Garage, special agents for Alldays Allon, Broadway, Muswell Hill, N.10, and Woodside Parade, North Finchley. [0027

ALLON, 1916, new lamps and horn, perfect condition throughout, owner emigrating; £45.—70, Ringstead Rd., Catford. [1546

ALLDAYS Matchless 4h.p., 2 speeds, F.E., enclosed valves, spring footboards, Amac, Bosch, new belt, good tyres, lamps, horn; offers.—50, Beulah Rd., Thornton Heath. [1767

1919 Allon Model de Luxe 2-stroke, hand clutch, 2-speed, kick starter and lightweight sidecar, as new, ridden only 40 miles; offers.—Surridge, 133, Sloane St., Chelsea, S.W. [1724

1915 Allon 2¾h.p., 2-speed, perfect condition, not run 4,000, good climber, smart, lamps, horn, tools, spare tube, tyres good; £55; after 5.—73, Cricklade Av., Streatham Hill, S.W.2. [X7412

F.O.C.H. have a 1919 Alldays Allon actually in stock, and brand new.—F.O.C.H. (Fair Offer Car House), 5, Heath St., Hampstead (near Hampstead Tube). 'Phone: Hampstead 3752. [9464

ALLON, recent model, 2-speed, Hutchinson tyres, saddle, lamps, pillion seat, all new, complete tools and accessories; £50; seen by appointment.—Adams, 50, Redcliffe Rd., South Kensington. [X7608

ALLON 1918 2¾h.p., clutch model, with light car, fully equipped, very smart turnout, starts easily, and goes beautifully, run 722 miles, practically as new; room reequired for car; £75.—Box 679, c/o *The Motor Cycle.* [X7297

ALLDAYS Matchless, 2¾h.p., 2-stroke, 1919 Villiers engine, new tyres, all accessories, in perfect order and condition; a bargain, £42; owner buying 2-seater car; call after 5 p.m.—87, Buxton St., Mile End, E.1. 'Phone Avenue 6787. [1424

1919 Alldays Allon 2¾h.p. 2-stroke, single gear, new August, run 1,500 miles, perfect order, Cowey speedometer, head and tail lamps, complete set tools, spare belt, etc.; £65.—C. F. Plowman, 27, Chancery Lane, W.C.2. 'Phone: 5516 Holborn. [1719

F.O.C.H. for the new Allon de Luxe, 2-speed, kick starter.—Book your order now for early 1920 deliveries, starting January. Our motto, "Strict rotation and no premiums."—F.O.C.H. (Fair Offer Car House), 5, Heath St., Hampstead (near Hampstead Tube). 'Phone: Hampstead 3752. [9469

Ariel.

ONE 1919 3½h.p. 3-speed Ariel, delivered September; £92.—P. H. Allin and Sons, 12, Bridge St., Cambridge. [1485

ARIELS for 1920, any model, no premiums, first deliveries.—W. T. Dunn, Ltd., 326, Euston Rd., London. [1887

1914 (Sept.) 3½h.p. Ariel Coachbuilt Combination, 3-speed countershaft; £78.—3, Cliff Terrace, St. John's, S.E.8. [1401

JONES' Garage, special agents for Ariels, Broadway, Muswell Hill, N.10, and Woodside Parade, North Finchley. [0028

1914 Ariel and Sidecar, 3-speed countershaft gear; price 99 gns.—Motors, Hampstead, 78, High St., Hampstead, N.W.3. [1634

ARIEL, 3½h.p., 3-speed countershaft gear, standard specification, just delivered; £95.—Cobb's Cycle and Motor Depot, Arbroath. [1576

"Some Folks are wise and some otherwise."

Smollett.

It is not always an easy matter to decide what to do—so much depends upon circumstances.

What are the chances of obtaining a new machine of your choice during 1920? If not already on a waiting list very little, we are afraid, as in most cases the demand far exceeds the expected supply. For this reason the following offer should appeal to most folk as

An Exceptional Opportunity

to get immediate delivery of a thoroughly reliable combination at a reasonable price.

Immediate Deliveries.

Cash or Deferred Payments.

5-6 h.p. **Rover,** Twin-cylinder J.A.P. engine, countershaft 3-speed gear, kick-starter, hand controlled clutch. Tool bag (no tools) and coachbuilt Sidecar with apron. W.D. finish. Makers' list price to-day **£188**

For Cash **£125**

For Deferred Payments

First instalment, **£34 10 0**

and twelve monthly payments of **£8 11 8**

8 h.p. **New Imperial,** Twin-cylinder, J.A.P. engine, countershaft 3-speed gear with hand-controlled clutch, kick-starter, tool bag (no tools) and coach built sidecar with apron. W.D. finish. Makers' list price to-day **£144 18 0**

For Cash **£135**

For Deferred Payments

First instalment, **£37 10 0**

and twelve monthly payments of **£9 5 0**

Mechanically these machines are perfect having had little or no wear; the original tyres being as new and in excellent condition.

Moreover each machine is guaranteed by Godfrey's

These combinations can be seen and inspected in our Show Rooms.

We are executing orders in strict rotation as received. Send yours in at once to avoid disappointment.

GODFREY'S Ltd.

BOOT

REPAIRING

"Elite Holdtite Rivetless Soles."

Soles STUCK ON.—

We are now placing on the market an entirely new and Patented Rubber Sole. These soles are specially prepared with an adhesive surface, and fixed with Elite Holdtite Sol-fix solution. **We guarantee them to hold as firm as rivets or sewing.** The process of fixing is exactly the same as that of repairing a punctured Motor or Motor Cycle tube. One of the many great advantages of our process is that the Boots or Shoes when fitted with our soles become **absolutely waterproof.** Full instructions given with each pair of soles.

SUNBEAM 1916 3½h.p. Combination, leg shields, Lucas equipment, maximum hand trip speedometer, spares, tyres perfect, good condition; £126.—18, Hestercombe Av., Fulham, S.W. [1862

SUNBEAM Combination, black and gold, August, 1919, little used, perfect, Lucas head and rear lamps, Klaxon horn, Amac; £152/10, no offers; taking over 8h.p.—Sims, China Stores, Chatham. Tel. 450. [X7487

1918 3½h.p. Sunbeam Combination, G.S. engine, new tyres, mileage under 3,000, perfect, any reasonable trial; £155; reason for sale taking 1919 model.—Vigornia, Barnsole Rd., Gillingham, Kent. [1880

1919 Sunbeam 4h.p., French military model, Henderson sidecar, Binks carburetter, Lucas lamps, horn, complete tool kit, spare jets, mileage 1,500; £140, or offers.—Rose, 18, Alma Rd., Heaton Moor, Stockport. [X7491

5-6h.p. Sunbeam-Jap 1914 Combination, nearly new Palmer tyres (rear light car studded), Gloria sidecar, just overhauled at cost of £20; expert examination invited; £140.—Lieutenant, 14, Parkhurst Rd., Bexhill-on-Sea. [1330

SUNBEAM Coachbuilt Combination, late 1914, war model, 6-8h.p., 3-speed countershaft, all chain drive, kick start, Lucas lamps, tyres nearly new, just overhauled, splendid condition; £130, or near offer.—Shaw, 1, Bath Place, Cheltenham. [X7234

1919 Sunbeam 3½h.p., as new, perfect, delivered only recently; £128, with good C.B. sidecar, £140, not ridden 800 miles, unpunctured; most carefully ridden and kept, could ride to London, owner buying car.—Offley Grove, Newport, Salop. [1759

SUNBEAM Combination, 1916, 8h.p. M.A.G. engine, interchangeable wheels, spare wheel, hood, screen, lamps, mechanical condition and appearance excellent; £145.—Longman Bros., 17, Bond St., Ealing; and 387, Uxbridge Rd., Acton. 'Phone: Chiswick 1578. [1781

1919 (June) 3½h.p. Sunbeam Combination, 3-speed, clutch, K.S., Lucas horn, lamps, Watford speedometer, saddle rest, insurance, tools, mirror; £145; owner's new position precludes use; letters.—Smith, 59a, The Grove, Wandsworth, S.W.18. [1660

1919 Magnificent New 3½h.p. Sunbeam, black and gold, not done 200 miles, fitted with Sunbeam leg shields, Lucas horn, large F.R.S. electric lighting set, speedometer, knee grips, special cut-out, other extras; £145 nett.—6, Churchways Crescent, Horfield, Bristol. [X6679

NO GERMAN SHODDY!
British throughout.

STANLEY BELTS AND FASTENERS

are World-renowned for their Reliability.

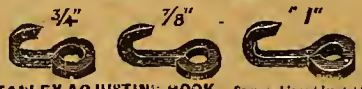
MILLIONS ordered and in use by H.M. WAR OFFICE and our ALLIES.

A BOX OF STANLEY SPARES is a complete belt equipment outfit—the best and cheapest insurance you can effect against belt trouble on the road. It contains

The STANLEY FASTENER with the BEND that NEVER BREAKS, the BEST at any price. Hardened & tempered hook and flanged pins.

The STANLEY SPARE LINK which is the best belt length adjuster yet invented. Saves time, trouble & money. Saves the cost of a new belt.

The STANLEY SHIELD which protects the belt fastener, prevents wear of the pulley, and conserves power. Specially designed for use with the Philipson Pulley. **9d.**



STANLEY ADJUSTING HOOKS for adjusting the length of your belt in one second. Set of 3 6d.

Never be without a Box of Stanley Spares.

Price 3/3 Post free. Send size of belt when ordering

The LION FASTENER, guaranteed for 5,000 miles—9d.

A STANLEY Fastener, free with each belt.

Send P.C. for two interesting booklets

Stanley Motor Belt & Fastener Co

STANLEY WEBB, inventor of the Original Belt Fastener and other Practical Devices

BROMLEY, KENT.

MAGNETO REPAIRS
and spare parts

We are well qualified to undertake the repair of Magnetos of all makes, and to supply spare parts, being, as we are, one of the most experienced firms manufacturing Magnetos.

SIMMS MOTOR UNITS, LTD.,
Percy Buildings Gresse Street, London. W.1.

MOTOR CYCLES FOR SALE.

Sunbeam.

1919 3½h.p. Sunbeam Combination, fitted sport sidecar; this machine has been specially b by Sunbeams, and is guaranteed to be the fast 3½h.p. machine on the road; just completed o trial, 62 m.p.h., with passenger in sidecar, gea 6—1; there are 2 spare gears in this machine solo work; the machine and sidecar are unscratcl and the smartest little 3½h.p. on the road; open best offers.—J. Smith and Co., 16, Hampstead H London. [1

T.A.C.

T.A.C., 4-cyl., 7h.p., 3 speeds, hand and foot clut handle starter, shaft drive, worm, sprung quar elliptic fore and aft, 2 external expanding bral footboards, horn, T.T. bars, Bosch mag., with cut-o B and B. carburetter, just been overhauled, ty perfect; owner going abroad; seen any time; tri £65, worth £75.—Hewson, Uplands, East She S.W.14. [1

Torpedo.

2½h.p. Torpedo Precision, engine new, Bosch, and B., tyres and condition good, P. and lamps.—Chatterton, 5, Northbrook St., Newbury. [1

Triumph.

1914 Triumph Coachbuilt Combination; 75 gns 143, Walworth Rd., S.E.17. [1

TRIUMPH 4h.p. Combination, late model, 3-sp countershaft, like new; £98/10.—Below.

TRIUMPH, 4h.p., 1914, 3-speed Sturmey-Archer, new; £68/10; cash wanted.—353, King St., Ha mersmith. [1

TRIUMPH, 3½h.p., clutch model, fast, reliable, j overhauled.—Mitchell, Halimote Rd., Aldersho [X72

TRIUMPH 3½h.p., clutch, good tyres and con tion; £45; week-ends.—21, Ardiland Rd., N [X74

TRIUMPH, 1914, 3-speed, clutch, perfect con tion; £60.—Collins, Casleton, Farnham, Surr [X75

TRIUMPH 4h.p., countershaft, in new condition, gine No. 44594; 68 gns.—55, Wiltshire Rd., Br too. [15

TRIUMPH 1917 Combination; this outfit is h new; £78.—51, Maplethorpe Rd., Thornton Hea S.E. [17

TRIUMPH Combination, late 1913, 3-speed, clut very little used; any trial; £80.—23, Thomas S Bath. [X73

1914 Triumph 4h.p. C.B. Combination, 3-speed, go condition; what offers.—38, Drayton Av., W Ealing. [X75

TRIUMPH Countershaft 4¼h.p., Dunlop heavies, good as new, fast, perfect; £72.—329, Old Fo Rd., E. [13

1911 Triumph, new Dunlops, lamps, belt case, perf order throughout; £30.—Haddon, 101a, Bro St., Coventry. [X76

JONES' Garage, special agents for Triumphs, Bro way, Muswell Hill, N.10, and Woodside Para North Finchley. [00

2¼h.p. 2-stroke Triumph, 2-speed model, accessor included; £52/10.—Wauchope's, 9, Shoe La Fleet St., London. [19

TRIUMPH, 1913, 3-speed, clutch, lamps, horn, et in perfect running order; £55.—18, St. Luk Rd., Clapham, S.W. [15

TRIUMPH, 1913, 3½h.p., clutch model, splend running order; £40.—10, Melrose Villas, B lard's Lane, Finchley. [96

TRIUMPH, 1917, countershaft, in new condition; reasonable offer refused.—Maddox and Co., Hammersmith Rd., W.9. [15

4h.p. Triumph, 3-speed, countershaft, new Palm cord tyres, etc.; £80.—Clapham (Motors), Ki George St., Greenwich, S.E.10. [19

1917 Triumph 4h.p., 3 speeds, countershaft, engi gears guaranteed sound condition; best offer 20, Valnay St., Tooting, S.W. [19

TRIUMPH, 1909, good running order, unused duri war, Millers lamps, tools, new belt; £30, or off —Maitland, Sauchieburn, Stirling. [X72

TRIUMPH, 1906, 3h.p., fixed engine, Bosch ma handle-bar controls, running order; £30.—Dav 34, Hill Rise, Richmond, S.W. [17

1919 Baby Triumph, as new, little used, perfect c dition, all accessories, etc.; owner buying c 65 gns.—Hawker, Davigdor Rd., Hove. [15

TRIUMPH, 1916, 3-speed countershaft, mach practically like new; genuine bargain, 62 gns.— Bennet Hill Rd., Kingston-on-Thames. [18

TRIUMPH, 3½h.p., Bosch mag., B.B., splendid ord take sidecar, N.S.U. gear; £38, or offer.—50, Clements Mansions, Fulham Cross, S.W.6. [13

1915 Baby Triumph, new Easter, 1919, done unc 500, tip-top condition, legshields, brand ne £60.—Flower, The Hill, Stratford-on-Avon. [X74

1919 Triumph, with new Montgomery coachbu sidecar, only done about 300 miles; £132.—K and Harper, 6 and 7, Bridge St., Cambridge. [13

NOVEMBER 13TH, 1919.

Passenger Machines.

THE words "passenger motor cycles" cover a field which is widening almost daily. From the earliest days of the motor cycle movement riders have evinced a desire to share their pleasures with other people, and by this desire they have extended the sphere of utility of motor cycles to a very great degree. First of all came the trailer attached to a single-geared motor cycle of perhaps 2 h.p. This was undoubtedly the least pleasant form of motor cycling, for the rider was compelled to pedal with considerable vigour on every hill, and the passenger received the full benefit of all the dust and smoky exhaust.

Next came the tricar, with the passenger in front, and this type had quite a vogue. Indeed, in the case of a well designed tricar, the seating accommodation was good, and, but for the fact that conversation was limited, and nervous passengers were apt to feel that in case of a collision they would be the first to suffer, the tricar might have become a very popular vehicle, in spite of the fact that it became somewhat over-developed and had an unfortunate habit of breaking its back, and of becoming somewhat unmanageable in the event of the rear tyre being suddenly deflated.

The craving for greater sociability was probably responsible for the first side by side seating arrangements, and from the early basket chair the sidecar has developed, in spite of mechanical difficulties, into the luxurious form in which we now know it. In spite of the great strides that have been made sidecar design has by no means reached finality. There are many details capable of improvement, though it is satisfactory to note that nearly all the weak points are receiving the serious attention of present-day designers.

Such events as the A.C.U. Six Days Trials show that sidecar frames can still be fractured under abnormal use, and that some form of spring wheel or flexible chassis is desirable. In this connection a modification of the old flexible sidecar may have possibilities, though the flexibility must be limited or the disadvantages of this type will again become apparent. Mudguarding, especially with regard to the front wheel of the combination, is still capable of improvement, and some form of sprung luggage carrier may be said to be a necessity.

Three and Four-wheelers.

Ever since the introduction of the three-wheeled runabout, certain of the lighter forms with side-by-side seating accommodation found a ready market, though until recent times there has been only one really popular survivor. The advantages of this type are many, but a large section of the motor cycling public appears to be prejudiced against three tracks. It is, therefore, interesting to see that there are symptoms of a revival of three track runabouts at the present time. A new factor is also making its presence felt in the introduction of well designed light four-wheelers, usually having air-cooled engines, and transmission on car lines. It is intended by the manufacturers that these little four-wheelers shall sell at the prices now ruling for motor cycles and sidecars, and if, by mass production, this end is attained, they will undoubtedly attract many adherents. The cycle car proper with motor cycle transmission also has its possibilities if only sufficient care is expended in the design of the chassis and transmission details, and it must be obvious to everyone that the type of passenger machine which sells at the lowest cost will prove to be the survivor, provided that it is capable of doing efficiently the work for which it is designed.

Thousands of motor cyclists will attend the motor cycle exhibition at Olympia with the purpose of purchasing either their first mount or a new machine to replace a pre-war model. Of these a very large proportion will be seeking a vehicle capable of carrying at least one passenger. For this reason, and perhaps for this reason only, it is unfortunate that four-wheelers are excluded from the motor cycle Show.

An Index to the advertisements in this issue will be found on the page facing the back cover.

Starting with a Broken Valve Lifter.

I AM much indebted to Mr. Frank for his kindly hint on pushing off with a shut throttle when endeavouring to start with the valve lifter out of action. I promptly tried it, and that it absolutely failed me is no fault of Mr. Frank's, for the machine has been a pig to start ever since it was delivered, and I have never had time to experiment with its adjustments. The engine in question has a colossal compression, alike in tightness and in ratio; it is no child's-play to get it going with the valve lifter available, at any rate in "maker's tune." Presently I shall have time to play about with it, and, when it is more docile, I will apply Mr. Frank's tip to it and report further. I remember having heard of the method before, but it had escaped my memory.

Climbing on One Cylinder.

RECENTLY, I took a 1915 machine out for a joy-ride. Approaching a freak hill, one cylinder stopped firing suddenly. I made no fuss for the moment, as the engine was full of oil, and the piston rings of the front cylinder were a trifle sloppy. In fact, I did not trouble to investigate, but merely dropped my feet, leant down and unscrewed the suspected sparking plug. Judge of my disgust at finding it in perfect order. I was now seriously alarmed—and well I might be—for the tappet, rocker, and rocker pin of an overhead exhaust valve were missing. I put the machine on the stand, and searched a wet and weedy ditch diligently for half an hour. By this time it was beginning to grow dark, and I was carrying no lamps. So at last, with the sparking plug removed from the idle cylinder, I made a start home. I was nicely trapped in a trough between two freak hills, one of which had to be climbed somehow. I selected the milder of the pair, which was nevertheless of the true A.C.U. kidney; and, by dint of a little foot-slogging on the worst knuckle, got home safely but slowly. The people who talk so glibly about overheating should have felt and smelt my engine after its long bout of full throttle on a gear of 14.1. Needless to say, it did not mind in the least.

The Limit.

IN the good old days, we motor cyclists used to buy small items germane to our hobby with a nonchalant recklessness. Tools and the smaller accessories were cheap then. A knot of the boys would meet in the evening at some local garage and scrutinise the showcases critically. If anybody saw a gadget which pleased him, he would put it in his pocket with a nod to the proprietor, and seldom trouble to ask the cost. We shall have to revise these easy habits. I was badly had a few weeks ago over an imitation 4½in. King Dick spanner, which was duly charged up to me at 7s. 6d. But I never dreamt of danger last week when I told my supply man to send me a foot and half of unplated copper petrol piping. This ridiculous little purchase figured in the bill at the portentous sum of 12s. 6d., and needless to say it is going back double quick. I will case-harden some macaroni rather than pay such a price.

The Fair Sex and Scooters.

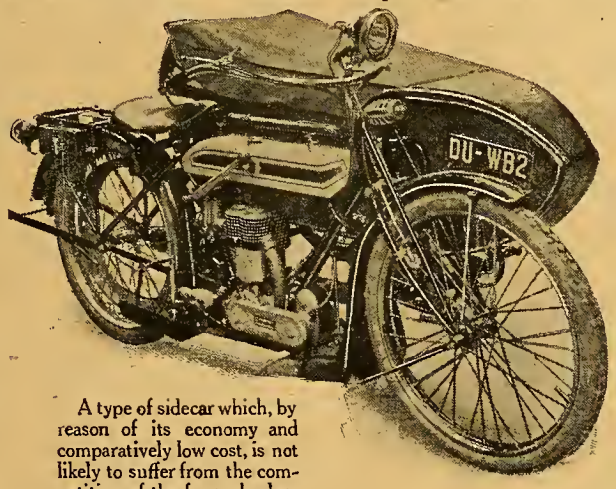
WHATEVER the future of scooters may be, there is no manner of doubt that women of all ages are intensely interested in them. Since their advertisements began to appear, hundreds of ladies, ranging in age from six to sixty, have questioned me about them. Some of the fair enquirers were joy riders in various categories—tennis players, golfers, and the like. But a large proportion were interested in the scooter from a purely utilitarian standpoint. For example, this week's enquirers include a district nurse, a widow who administers a small but scattered property, a rural housewife, and other short-distance travellers, few of whom will see forty again. I am specially struck by the motives and the ignorance of these enquirers. Without exception, they are attracted by cheapness and lightness. They funk motor cycles, because even a lady's model Douglas is too heavy for them, and also because they will not or cannot expend £60 or more. They are waiting for something at about £30, and weighing considerably under 100 lb. I do not say that they may not in time accept a £50, scaling 120 lb., if development trends in those directions; but they would not look at such prices and weights just yet. In the second place, they are woefully ignorant of the fundamental facts. None of them know enough to ask whether the particular scooter which has tickled their fancy can climb steep hills, or is comfortable to ride, or prone to skid, or maintain its power. They take hill-climbing for granted by analogy with cars; for similar reasons they imagine that a nominal 1½ h.p. engine necessarily develops 1½ b.h.p. after a thousand miles. Some of these good ladies have actually never ridden push-bicycles, but are game to begin scooting as soon as they can get delivery. It is obvious that the A.C.U. must hold their scooter trial as soon as production is in sight; and that the riders should be women, for preference, and in other respects the trial bristles with thorny little problems. It must be long enough to identify those wee engines which do not fade away after two or three hundred miles; at the same time 1,000 miles would be a purgatory for the riders. It must include hills steep enough to reproduce average riding conditions in our hillier counties; yet there must be no crop of failures on these hills. 'Pon my word, I think I'd rather organise ten T.T. races than one scooter trial.

The Passenger Outlook for 1920.

The Coming Contest between the Three and Four-wheeler—Price the Deciding Factor.

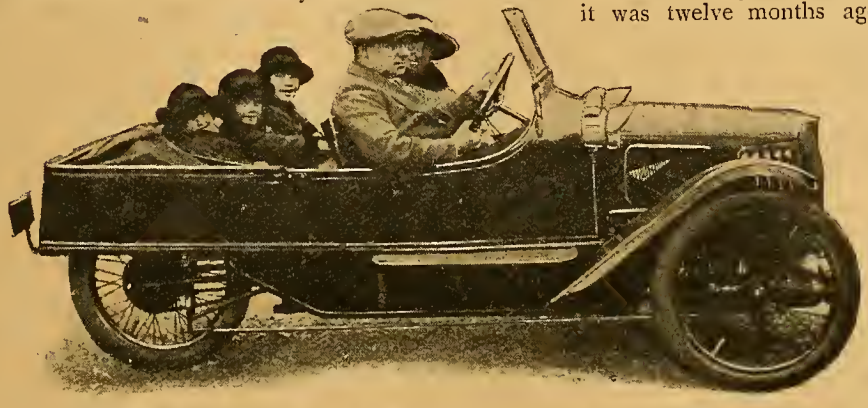
By B. H. DAVIES.

I HAVE not yet seen any printed recognition of the outstanding factor in the passenger outlook for 1920. For perhaps the first time in the records of the industry four-wheelers—and sound four-wheelers at that—are on offer at lower prices than some of the best sidecar outfits. To quote an instance, the Speedy light car (four wheels) is listed at 110 guineas. I know very little of this vehicle, but it is stated to be a mass production job, and its figure is nearly fifty per cent. *lower* than that at which a number of the most famous three-wheeled outfits are rated. But the sidecar will probably meet more formidable competitors in sundry light cars which command higher prices. The A.B.C. sports-car (with a four-speed gear box and a differential), the Cosmos (with a three-cylinder engine and dynamo lighting), and the Rover (with a car reputation corresponding to that of the Triumph Co. in the motor cycle industry), are all four-wheelers at prices which represent the average for a first-grade high-powered three-wheeler, and may indeed be rather beneath the sums asked for certain motor cycles and sidecars.



A type of sidecar which, by reason of its economy and comparatively low cost, is not likely to suffer from the competition of the four-wheeler.

Frankly, I hardly know what to make of this extraordinary situation. Some will say that a three-wheeler is not so suited to modern "production" methods as a four-wheeler, and is bound to be undersold when an expert manufacturer goes the whole hog on a cheap car. Some will claim that the three-wheeler lends itself admirably to production methods, but that no firm in the world has yet applied those methods to three-wheelers, *i.e.*, that existing combinations cost a good deal more than they would if Sir Henry Austin had stooped to them. There may be truth in both theories. For myself I adopt a third line. These new cheap cars are very new indeed. The general public suspects them of savouring of the experimental, and is also extremely dubious as to when mass deliveries will commence. On the other hand, we know the best and the worst of the sidecar and the three-wheelers generally; we have had business dealings with the firms who make them; we trust their delivery promises (with not too big a pinch of salt); and we know that the modern sidecar outfit *de luxe* is extraordinarily fast and reliable, a magnificent climber, and cheap to run. It has had years of concentrated development, and at last it is alike well fitted, well designed, and well made. So—even if we can get a four-wheeler for the same money, we only vouchsafe one regretful glance at the superior driving comfort which the latter affords; sure delivery of a proved article by a known firm counts for much. Incidentally, these are days in which it does not pay to delay a decision. A new motor is not a great deal easier to get than it was twelve months ago, when frenzied men paid two or three hundred pounds for dusty old junk hardly deemed worth storage room in 1914, and destined for the marine store as soon as a lorry wanted a load. We ordered; we may not have got delivery yet; but we have waited six, nine, or maybe



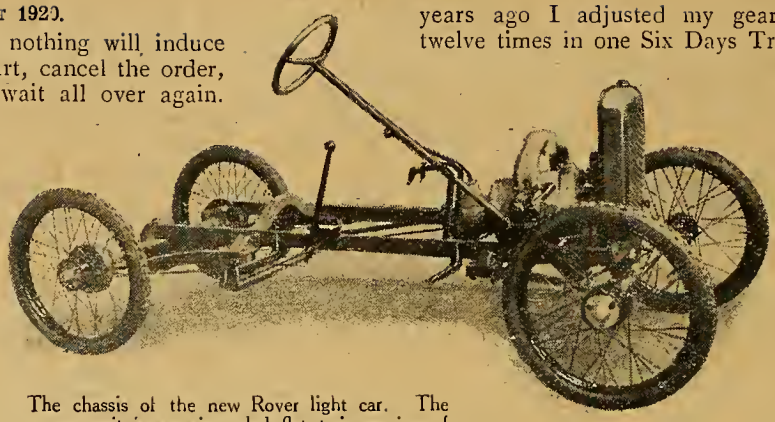
The latest Morgan will go far to meet the requirements of the "family" man, who found the ordinary body too small to accommodate an extra passenger.

The Passenger Outlook for 1920.

twelve, months; and nothing will induce us to call it a false start, cancel the order, and begin the weary wait all over again.

In twelve months' time things will get exciting, so far as the cheap transport of two persons is concerned. Some of us will be so poor that the carrier of a baby two-stroke will be all we can offer to the damsel who takes our fancy. But all of us will see a battle royal between the cheap cycle car-light car hybrids and the three-wheelers. The lists are already set out for the tourney, but the joust has not begun, because in these days you can sell anything that has a carburetter on it. I will not venture to prophesy the ultimate victor. But it is clear that, if lean years are coming, the cheapest vehicle which will do the work has the best chance. From a production standpoint, the Morgan type of three-wheeler is better than the sidecar outfit, and a sidecar, produced on a scientific system in quantities, ought to have a few pounds in hand of any decent four-wheeler.

Stepping back into the real province of this journal, there are three main features to chronicle. The first is that the single-cylinder sidecar outfit is at last equal to that of any country. Engine cooling now permits us to use any low gear ratio we may fancy. No hill can stop the modern 3½ h.p. sidecar. The second high spot is the phenomenal quality of the *de luxe* combinations from every point of view. Of this, more anon. The third is the fact that several firms have learnt from the Morgan that there is still money and fame in what used to be known as a "tricar," and is now rechristened a "runabout."



The chassis of the new Rover light car. The power unit is an air-cooled flat twin engine of 85 × 88 mm. (998 c.c.), built integral with a three-speed and reverse gear box. Simplicity and light weight are the keynotes of its design

The Dogged Single Cylinder.

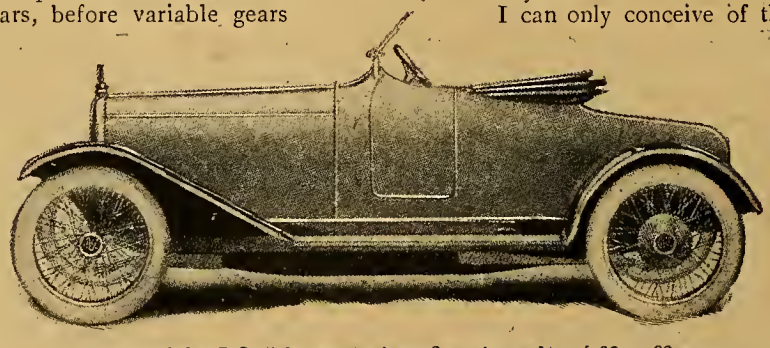
Never before has it been possible to select a 500 c.c. single, almost at random, put a sidecar on it, plan a route without any timidity about hills, load up with a wife (fat and forty, if you like), the baby and/or twins, and/or triplets, the corresponding luggage, and surge with an even mind up the worst hills in our islands. For many years, before variable gears came in, we used to do this sort of thing, and run alongside up a hill like Dashwood, breathing like a gold-fish that has leapt out of its bowl. Then variable gears appeared, and hill-climbing became anxious for other reasons. Sometimes the gears would not gear (seven or eight years ago I adjusted my gear box—think of it—twelve times in one Six Days Trial); more frequently the engine objected to 800 yards on an 8 to 1 gear, and showed its resentment by knocking or seizing or pre-igniting or scaling a valve. To-day any duffer on any 500 c.c. machine you like, with a well-nourished fairy in the sidecar, deserves expulsion from all his clubs if he cannot climb Sutton Bank with something in hand.

When we turn to combinations of 8 h.p. or thereabouts, there is even more room for pride. If any reader has not sampled a recent model over a wicked course, I advise him to do so without delay: it takes a very hot car to hold it. On one occasion this summer I put a 1919 8 h.p. over a peculiarly appalling route: so bad that I would not have sent a car of my own over it. The outfit held the road like a postage stamp, shook us less than most good cars would have done, took practically everything on second, travelled so fast that a good rider on a very hot single could not leave us, and never turned a hair in a gruelling that was calculated to fracture a tank.

The Sidecar *de Luxe*.

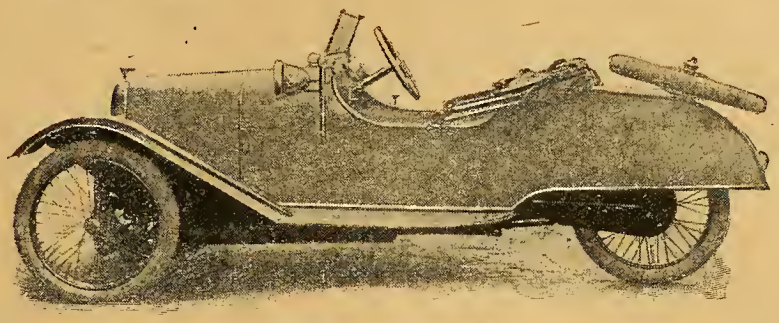
The Llandrindod Trials provide additional evidence on such points, and we ought not to forget that the lightning steering, high speed, and side wrenches to which sidecars are by their nature subjected, intensify the severity of such tests. Moreover, if the big sidecar is capable of feats, it has also become delightfully well equipped, so that it is very convenient to handle. Its lighting outfit compares with those of the best cars. It possesses interchangeable wheels of equal handiness. Its chair is comparable in comfort with the best seat in the best car; indeed, I know many people who prefer a good sidecar to a big car if they are called upon to ride through an Edinburgh. Windscreens and hoods are obtainable for those who fancy them.

I can only conceive of three details in which sidecars of the best type are not perfect. The first defect is presumably inevitable: the exposure of the driver can be minimised, but he can hardly be protected in a fashion which compares with car comfort. More can be done, and will be done, but this is the sole real snag. The second



The air-cooled A.B.C. light car, having a flat twin engine of 92 × 92 mm (1,223 c.c.) The intention is to produce this little vehicle at the comparatively moderate price of £200 or thereabouts.

is still, to my mind, undervalued by designers. The passenger of a sidecar is seated low down, very close to the road, and where there is surface water about, a good deal of liquid dirt is apt to enter the body. The mudguarding of the front and side wheels deserves closer attention, and the fitting of a windscreen is a coward's solution, for in summer it is best to take the breeze on one's face. The third point is also worthy of factory attention. As I have already stated, the reliability of the sidecar outfit is high. But when attention at last becomes necessary, the mechanism is seldom decently accessible. The presence of the body is an obstacle which a cunning engineer will outflank, either by unhitching its front end and tipping it, or by transferring vulnerable items to the far side of the chassis, or by a variety of dodges. But, quite apart from this, some luxurious sidecars are a veritable jungle of piping and rods and wires and gadgets. We love a machine which serves us well on the road; but we reserve the depths of our affection for one which serves us no less pleasantly in the garage. In this respect the high-powered sidecar outfit still falls below the standard which rival types of motor have set.

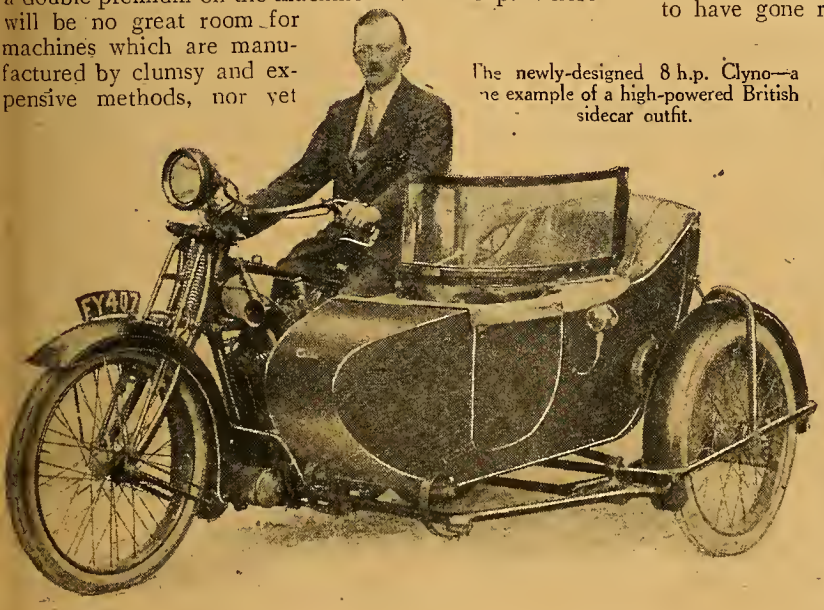


The Coventry Premier—an example of the fully developed three-wheel runabout which at the same time does not appear as a car on three wheels.

Comfort a Great Feature.

It is quite on the cards that the tricar or runabout type of three-wheeler has a brighter future than the sidecar. The three tracks and the single driving wheel are weak points in theory. The latter is shared with the sidecar, and the former is more than balanced by the comfortable driving seat and the level seating of the crew. Driving comfort is a very, very strong point indeed; and it is possible to argue that the chassis can be a better production job than a sidecar frame. If that is so, it means much.

Probably the keynote of the future market—say in 1921 or 1922—will be over-production by the trade and rentrenchment by the user. Such conditions put a double premium on the machine that is cheap. There will be no great room for machines which are manufactured by clumsy and expensive methods, nor yet for machines which are awkward to make because of their design. Some authorities, rightly or wrongly, regard the three-wheeled runabout as more likely to flourish in those days. The Morgan is no longer alone in that class. Few of us know what the Premier and the Merrall and others of the type can do; we know them only through the columns of the technical press. But we shall watch them very closely. I shall speak for a large public if I say that we do not necessarily expect a full motor car specification from a three-wheeler *The Motor Cycle* readers include thousands who once enjoyed road work on single-geared sidecars and forecars: aye, and on trailers. Some such have been hard hit by the war. Others are not rich, and never will be. We cannot help thinking that the gap between our old single-geared atrocities, with their wicker chairs, and the modern 8 h.p. cum-dynamo, cum-three-speed gear, cum-lots of other luxuries, has never been perfectly filled. We visualise a simple three-wheeler, with protection and comfort for the driver, produced in quantities at a low price. Perhaps when the battle between the sidecar *de luxe* and the air-cooled light car has been fought out, some genius will Fordise the three-wheeler for men of the class I have indicated. During the war I heard yarns of a machine with a 4 h.p. flat twin engine, an ash frame, and an infinitely variable gear, which sounded as if it might have filled this particular bill; but it seems to have gone right west.



The newly-designed 8 h.p. Clyno—a fine example of a high-powered British sidecar outfit.

The Super Runabout.

On the other hand, there is evidently a permanent place for the runabout *de luxe*. Its chassis can always be as simple a job as that of a cheap four-wheeler, and it will always be cheaper by at least the cost of a wheel and tyre. It is perhaps surprising that no runabout has yet appeared with one of the better types of engine. Frame difficulties hamper the sidecar designer who wishes to fit a four-cylinder or a flat twin. No such problems affect the lay-out of a runabout. Nobody can pretend that the best V twin is quite as nice as a good four or flat twin. We might never have seen a single V twin but for the peculiarities of the standard motor cycle frame, and it is certainly odd that this engine monopolises the high-powered motor cycle field, irrespective of frame contours.

The Passenger Outlook for 1920.

Let me talk seriously. There are several controversial theories about scientific production, but the mildest of them presupposes a minimum output of 10,000 per annum. Now, the largest British pre-war output of solo machines was little more than half that number, and I do not suppose that any sidecar or runabout specialist ever approached an annual output of 2,000. Several very simple cars or cycle cars—call them which you will—have engaged expert staffs, laid down new plant in new factories, and are organising for outputs of 10,000. They will turn out good stuff, and undersell the sidecar and (probably) the runabout. Unless suitable action is taken, the result would be that the runabout would disappear altogether, and that sidecars would survive only as auxiliaries fitted to standard solo machines. This would be an evil in two main respects. In the first place, rationally or irrationally, quite a lot of men are sidecar enthusiasts or maniacs. They would rather drive a sidecar (or a runabout, as the case may be) than anything else. They will be restricted to the "gum-on" sidecar with any bicycle you please. Secondly, other things being equal—design, production, etc.—a three-wheeler must be cheaper than a four-wheeler; and if production methods are not applied to the three-wheelers, impecunious motorists will be deprived of a mount which suits their purse.

Mass Production of Sidecars.

For these reasons I expect the three-wheeled trade will shortly undergo a marked transformation. Somebody will organise mass production of detachable sidecars for a certainty. The small outputs of complete combinations will get hard hit as time goes on. The small outputs of three-wheeled runabouts will also feel an increasing breeze. The logical outcome will be a marked reduction in the number of makes. Production light cars (or cycle cars) will eat into the passenger motor cycle market in due course: they are doing so already, though the motor famine conceals the extent. The correct counterblast is threefold:

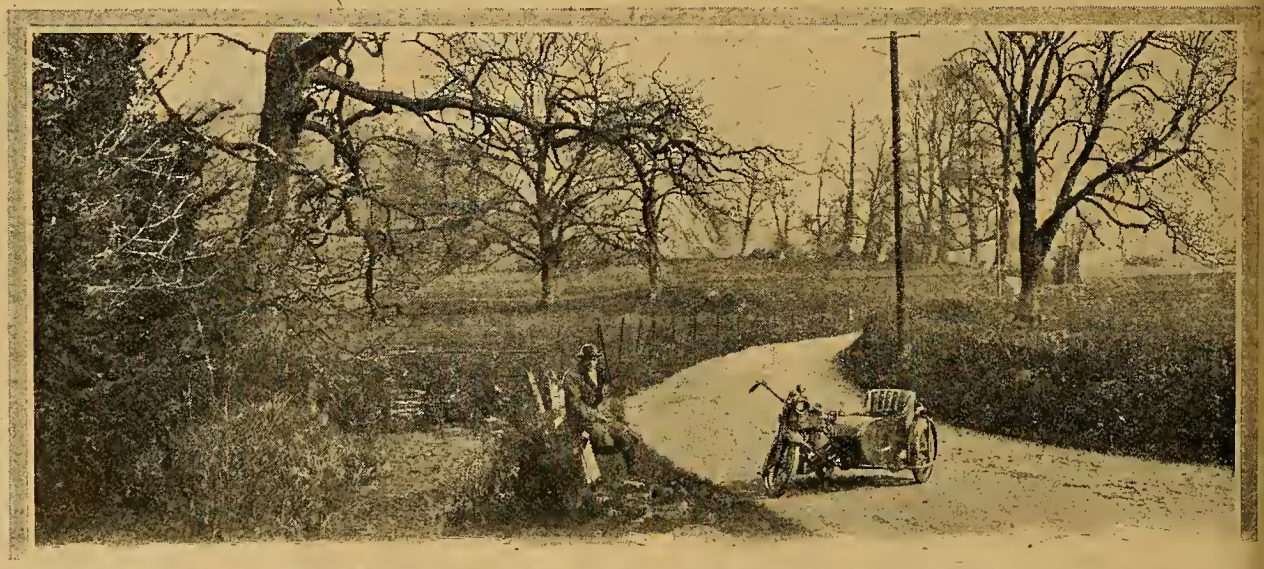
(1.) Mass production of detachable sidecars by a few firms.

(2.) Mass production of complete combinations by a few firms.

(3.) Mass production of runabouts by a few firms—let us hope one runabout *de luxe* and one cheap, simple runabout will figure in the list.

Open Minded Users.

I have said so much about the new light cars and cycle cars in general terms that I ought to close with a few particulars. I have personally tried many of these designs. I ask any open-minded user what chance the sidecar and the three-wheeled runabout have against the 1914 type of water-cooled four-cylinder light car? The answer is obvious. We all know many ex-motor cyclists who have bought Singers, Calcotts, Calthorpes, Morris-Cowleys, and what not; but few of us can cite a solitary individual who has made the reverse change except under financial compulsion. It is quite commonly suspected that the new air-cooled cars compare most unfavourably with the 1914 light cars. I daresay some of them do. Those I have tried do not. The components which are common to both have been improved: the engines, gears, brakes, springs, and bodies of the newcomers are appreciably better. The climb is faster. The speed on the level is higher. The petrol and oil consumptions are superior. The cooling is fractionally better—the 1914 types steamed on really bad hills, the 1919 types show no deficiency in cooling. It is a moot point whether the fuel and the sound of a flat twin engine with two fair sized cylinders will please the average user more or less than the smooth burr of four lilliputian cylinders. But the cream of these newsters is quite extraordinarily good. And they are listed at lower prices than will be asked this winter for quite a lot of three-wheelers. Hence I am sure that the three-wheeler industry as a whole will have to get a big move on during the coming year, for the days have ended in which costly methods of turning out a thin trickle of machines can earn a dividend.



An autumn scene near Ledbury Bromesborrow. The modern motor cyclist does not store his machine with the fall of the leaf, but continues his motor cycling throughout the winter, even though his riding may be purely for pleasure.

Official Notes on the Six Days Trials.

Extracts from the Officials' Report upon the Recent Event in Wales, together with Suggestions for the Next Six Days Trials based upon this Year's Experiences.

IN submitting the judges' report of the recent Six Days Trial (published last week), the chairmen of the General, Competitions and Touring Committees—Messrs. A. W. Torkington, E. P. Greenhill, and H. P. E. Harding respectively—made the following suggestions for consideration of the Competitions Committee for future trials:

(1.) That a speed test at the conclusion of the road trial, in which engines would be required to run at full load for, say, half an hour on such a track as Brooklands, would go far to eliminate the necessity for a detailed examination of condition at the finish.

(2.) That if a speed test is not practicable a more complete examination of the machines should be made, in which the vital parts should be taken down and inspected. For this purpose it would probably be necessary to extend the time of the trial.

(3.) That the competitor or a representative of the entrant should be present at the examination of that machine after the trial in order that he may understand the reasons why marks are lost on examination, and to enable these points to be corrected in manufacture.

In commenting upon the course and weather conditions, the judges stated that the 1919 trial was organised to encourage the improvement of the motor cycle to such a pitch that its usefulness will be increased and not in any way restricted.

Referring to the course, the promoters stated that the route chosen was not so trying as to gradients as in the 1914 trials, but, by length of hills and persistency of strain, was more representative of the worst treatment to which a motor cycle might be expected to be subjected whilst in constant use under ordinary conditions.

Weather Conditions.

The trial was held with Llandrindod Wells as a centre, the competing motor cycles being parked every night in the Drill Hall and another depot near by. Monday morning was devoted to the preliminary examination, and the road test commenced at 2.30 p.m. in fine weather with 111 starters. The mid-run control this day was from 5.30 to 7 p.m., so that for the homeward journey lamps were required to be lit. No lamp failures were observed.

On Tuesday (110 starters) the weather was again favourable, and, in spite of the numerous watersplashes and rough going, schedule time was well kept.

Wednesday (102 starters) was again fine, but a thick mist for the first forty miles or so was troublesome.

Thursday (93 starters) was fine until the afternoon, when a drizzling rain commenced which got worse as the trial proceeded, and added to the difficulties of the route.

Friday (84 starters) started with showery weather, but the morning's run was comparatively easy. The afternoon, however, continued showery, and, as the route was the most difficult of any half-day, the performances of the eighty-two finishers, of whom seventy-four checked in punctually, were creditable.

The relatively large number of those who finished, the high proportion of medals awarded, and the small proportion of marks lost under the headings of reliability and hill-climbing, indicate that the route chosen did not err on the side of severity. On the other hand, the daily mileage was unavoidably greater than the judges consider desirable, as such distances must severely test the personal endurance of the drivers.

Maintenance of Tune.

These tests were conducted simultaneously under the title of the "Consistent Driving Test." The judges consider that such a term is liable to give an erroneous impression, and they would recommend that in future tests of this description the personal driving element should be discounted by arranging that a better performance on the second occasion of the hill-climb should be called for rather than a repetition of the first performance.

Comments upon Design.

The judges regret to see so few examples of the larger multi-cylinder engine, both four and two-strokes; they consider also that attention might usefully be directed to water-cooled multi-cylinder two-strokes for sidecar use where cleanliness, together with the absence of uneven torque, noise, smell, and dirt is of maximum importance.

The Scott engine is worthy of very special commendations as to the above requirements.

The importance of the final examination and the basis of marking in connection therewith appear to have been somewhat misunderstood. In previous Six Days Trials, a maximum of 12½% of the total losses was possible under "condition at finish," and in practice only 6% was deducted for such a serious fault as a frame breakage, whilst comparatively small faults, such as the steering head bearing slightly worn, were not penalised at all. In the report of the 1914 trial, the judges drew attention to this and strongly recommended that in future trials the condition at the finish should be a much more important factor in determining the final award. This year a maximum loss for final condition of fifty marks (25%) was laid down, and the judges were instructed that only machines which finished the trial in perfect condition and adjustment should retain full marks.

It would appear that the need of rapid accessibility and low gears has prevented a more general use of enclosed transmission in a Six Days Trial, whilst the belt drive continues to satisfy both makers and users in the present transitory period.

The judges regret the absence of any examples of shaft drive, which lends itself admirably to total enclosure upon a machine of general utility. A general improvement in gear box condition was noted, though the adjustment of about 30% was found faulty.

Bearings.

There is room for much improvement in this respect, as sideplay interferes greatly with steadiness of steering.

A great deal of play was noticed in the steering heads of many machines, showing either inadequate ball bearings or the absence of provision for proper lubrication. Larger bearings would appear to be desirable in most cases, or a longer head.

Sidecars.

The oustanding point of the modern sidecar combination is, apparently, its extremely inartistic appearance. These outfits, with few exceptions, compare unfavourably in appearance with the cycle car type of vehicle, and, as they afford little or no protection to the driver, it is necessary that they should excel in other directions.

It would appear that the bad roads, now common, together with tyre failure, are sufficient to cause a distinct liability to fracture, alteration of alignment, and spring breakages of sidecar chassis.

The judges would draw attention to the fact that where severe stresses have to be considered due to the road and the inertia of the motor cycle itself, the possibilities of flexibility and springing are greatly neglected.

Sprung bodies may increase passenger comfort, but they do little to reduce unsprung weight or to relieve the frame itself. The unsprung weight of some outfits must approach that of a relatively large and heavy car, and the mere stiffening of the chassis of the combination cannot cope with the strains set up by the prevention of relative movement between the wheels of the sidecar and the motor cycle. An endeavour to prevent breakages or to resist stress by the addition of weight is extremely unsatisfactory.

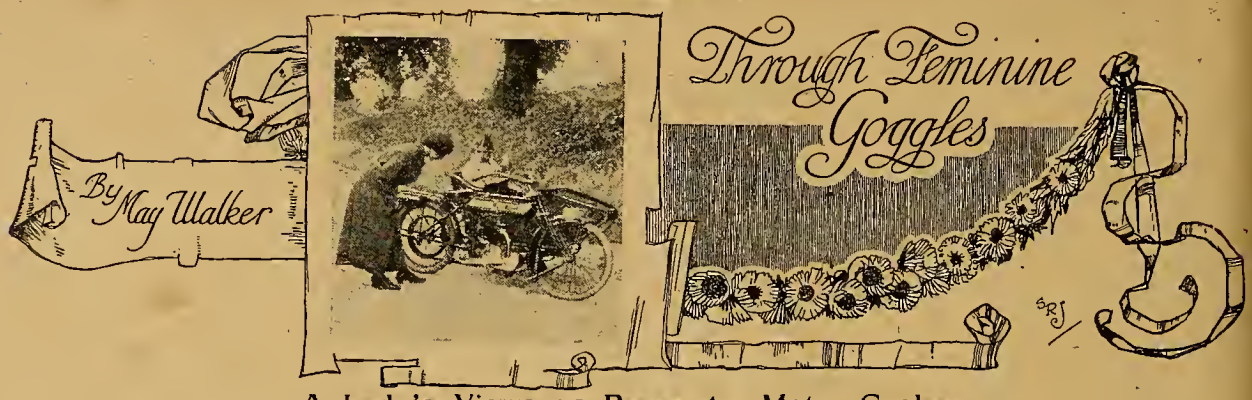
There is very great room for improvement in the attachment of sidecar mudguards, and, as it appears to be almost hopeless without unduly heavy and clumsy stays, etc., properly to secure them to the unsprung portion of the sidecar chassis, the obvious solution seems to be to attach the mudguards to the sidecar body.

Silence.

Silence and cleanliness, together with ease of cleaning, appeal to many people far more than speed, and there is no valid reason why these characteristics, supplemented by increased comfort and radical redesign of control should not approach car conditions.

The judges feel that severe condemnation of these faults alone will help to produce eventually a machine of universal appeal. The motor cycle would thus possess a far larger sphere of usefulness, and, for convenience, cost, and economy would be unapproachable by any other form of road vehicle.

The judges were Lt.-Col. A. E. Davidson, D.S.O., Mr. H. H. Gregory, A.M.I.M.E., M.I.A.E., Maj. A. M. Low, D.Sc., A.C.G.I., etc., Lt.-Col. D. F. Nicholl, D.S.O., and Mr. T. W. Loughborough, A.M.I.A.E.



A Lady's Views on Passenger Motor Cycles.

THE greater number of machines marketed to-day are designed for passenger use. Even the sporting solo rider, as the wintry weather draws in, often couples up a sidecar to make his mount less liable to skids, and, finding the convenience that accrues from the attachment, he is likely to continue it when drying roads no longer make it a thing of necessity. There is no doubt that the passenger machine supplies the cheapest form of motoring for two, with the exception of pillion riding, which, personally, I do not recommend. For business purposes, for carrying the tradesman's wares, or for a day's trip in the heart of the country, it is the mount *par excellence*. It will accommodate two or three persons, guns, and dogs, and will go wherever there is a good enough surface to provide wheel grip. It can also be turned into a gateway and there left till the day's work or play is over.

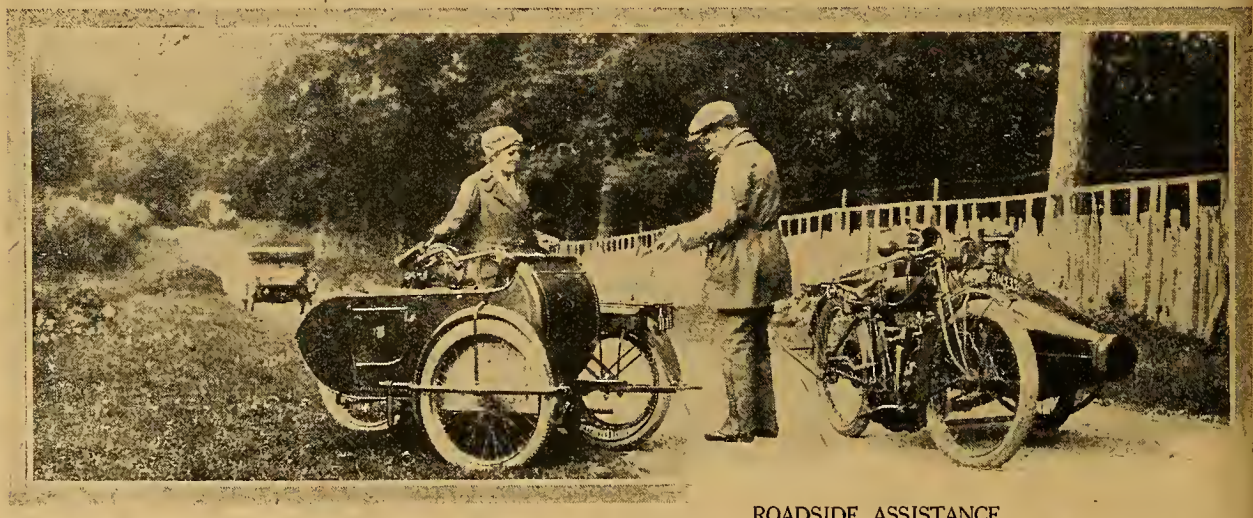
Some Desirable Features.

I have owned many types of sidecars, and each season find improvements on the old. The modern sidecar is as unlike its early predecessor as the pneumatic tyre to the solid variety. Yet I have still to find my ideal in every particular. All first-class makes have their good points, and if I enumerate a number of them perhaps some day an enterprising manufacturer will carry all my fancies to actuality.

Probably the first thing that attracts the feminine eye is the contour and lines of the bodywork. The torpedo or streamline effect is most pleasing, but ease and comfort must not be sacrificed to effect and shape. A bulbous back (favoured by the James Co., the Gloria Sidecar Co., and others in their 1920 models) provides the last word in elegance. The ideal sidecar that I am looking for must have the bulbous back with a large locker opening outwards, another locker under the seat for carrying spares and articles to which one needs to resort less often, a roomy body allowing plenty of freedom for the feet, a footboard such as Ariels fit to their sidecar, and, of course, a door. I must also have a spring wheel, for of all the types that have passed through my hands I have found none that give such a marked degree of comfort. One needs a sidecar so designed that cramping on a long journey is practically non-existent. Those tiny contraptions that are often affixed to speed mounts may be very well for short jaunts, but something more practical and substantial is required for long journeys.

Luggage Accommodation Essential.

Again, the reclining attitude with an absence of backrest is not the most comfortable. To return to my ideal. I want more lockers still. The sliding drawer that is fitted in the toe of the new Enfields is a step in the right direction; the double thickness



ROADSIDE ASSISTANCE.

There may be grounds for the present day complaint of lack of roadside courtesy when the stranded one is a mere male, but we still await news of a lady motor cyclist being refused immediate assistance when held up by trouble with her machine!

Through Feminine Goggles.—

of wood, too, should help towards warmth, and maps and small odds and ends can be kept here out of the way. When I go visiting for a few days I need a special kind of locker, as it is impossible to pack one's best frock in any of the lockers I have seen provided. The receptacle for that must be of suit case shape and impervious to dust. I am aware that I can attach a case to the luggage grid, but it is fairly troublesome to strap on, and I generally find it has worked loose enough to jar against the back of the sidecar and scrape off paint. The best arrangement would be a permanently fitted aluminium suit case, or, rather, three cases in one, capable of expanding to two or three tiers as necessary. I should then only need to lock the lid and be relieved of all the bother of strapping. In addition to this, I want a fixture for carrying the spare petrol can upright, somewhere between the motor cycle and sidecar, lined with very thick felt to prevent rattling. At present the usual place is on the carrier, and it goes to one's heart to find at the end of a journey that precious spirit has leaked along the road.

Family Sidecars.

Various types of tandem sidecars have appeared on the market, and though these are usually not pretty, where the whole family has to be taken out, usefulness must stand before beauty.

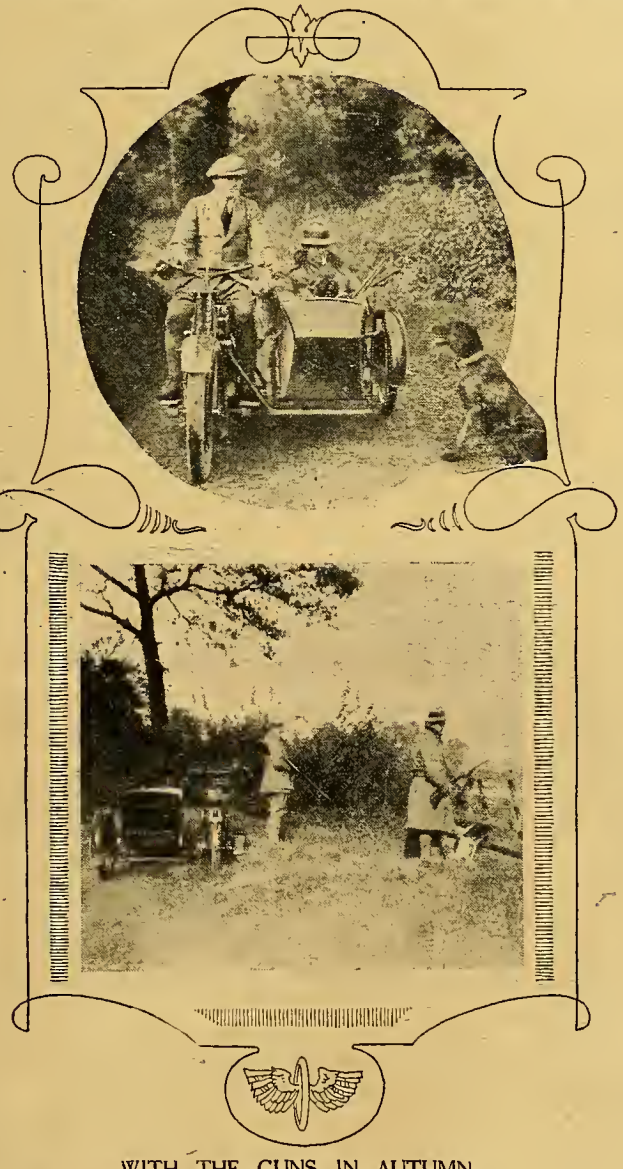
The most luxurious modern sidecars are fitted with hoods and side curtains, so that the occupant has all the advantages of a closed carriage, but though such fittings are most useful and comfortable for those who enjoy them, a hood has no attractions for me. I feel that the few times that I should need to use it would not justify the weight and expense. All else being to my fancy, I could dispense with a windscreen. One might provide one for an elderly passenger, or one who never intended to take a turn at driving, but I bring up my passenger "in the way she should go," and if I am ever to have a taste of the luxury of the sidecar, I must not allow a screen, or she would never come from behind its sheltering folds. I once had a screen made to my own design and fitted for the comfort of a delicate passenger, but on recovering health she soon required its removal.

General Appearance.

These additions that I have mentioned add to the weight of the outfit, and are more suitable where the power of the machine is more than 4 h.p.

Mudguarding of the sidecar wheel is an important point, and should be ample; a wide guard gives a better finish besides serving its purpose better. Most firms, however, are giving more attention to protection from mud and dust; we hope the rest will follow.

Some of the latest sidecars are certainly striking in appearance, and one of the most pleasing colour schemes is mauve bodywork edged with aluminium. The passenger is generally a member of the fair sex, and to her colour is a great attraction, although drab tints may satisfy the mere man.



WITH THE GUNS IN AUTUMN.

The utility of the sidecar strongly appeals to the sportsman who finds it a great convenience in reaching home from outlying parts of country.

At the Show, now so close at hand, we all hope to see our own individual tastes indulged and ideals realised. Already in our mind's eye we can see the gay stands at Olympia, the salesman expounding the good points of his models and slurring over any faults in design. Human nature is often provoking, and patience is required by the stand attendant.

Future Developments.

The war hindered evolution in all except engines, but once the world settles down again, and motoring questions are tackled in an enterprising spirit, the accumulation of experience gained during the past five years' time should produce some really fine designs in which both motor cycle and sidecar are manufactured under the eye of one designer who has considered them as essentially inseparable in so far as the mechanical conditions of springing, power production, transmission, and accessibility are concerned. In the latter case we may hope to see the universal employment of interchangeable wheels, all-round springing, and luxurious accommodation for the passenger, together with ample luggage carrying capacity.

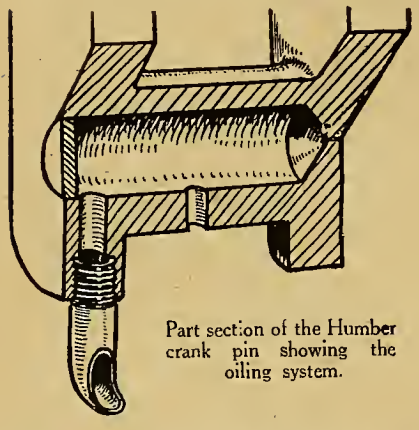
NEW MODELS.

A 4 h.p. HUMBER FLAT TWIN.

FOR some time past we have been aware that Messrs. Humber, Ltd., have been experimenting with a passenger machine on the lines of their well-known 3½ h.p. flat twin, but having a rather larger engine.

Recently, we were afforded opportunity of examining this new production, and of having a short road test.

At first sight the new 4½ h.p. model so closely resembles the 3½ h.p. that one might be forgiven for mistaking the two types. However, closer inspection reveals several modifications which are of considerable importance, although they are not very conspicuous.



Part section of the Humber crank pin showing the oiling system.

The engine has a bore and stroke of 75 × 68 mm., giving a swept volume of 600 c.c. As in the 3½ h.p., both inlet and exhaust valves are readily detachable with the seatings and pockets. A new feature, however, is incorporated in the lubrication system, for a gear type oil pump, driven from the crankshaft, raises oil from a sump below the crank case, and delivers it to constant level troughs.

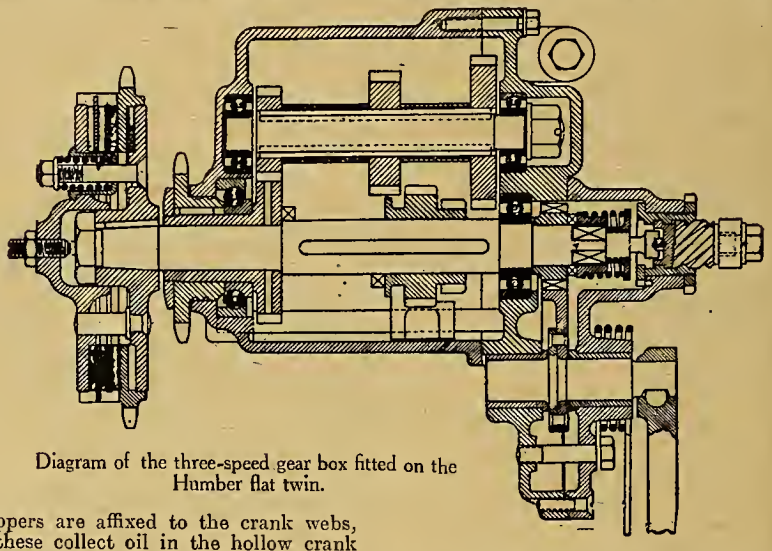


Diagram of the three-speed gear box fitted on the Humber flat twin.

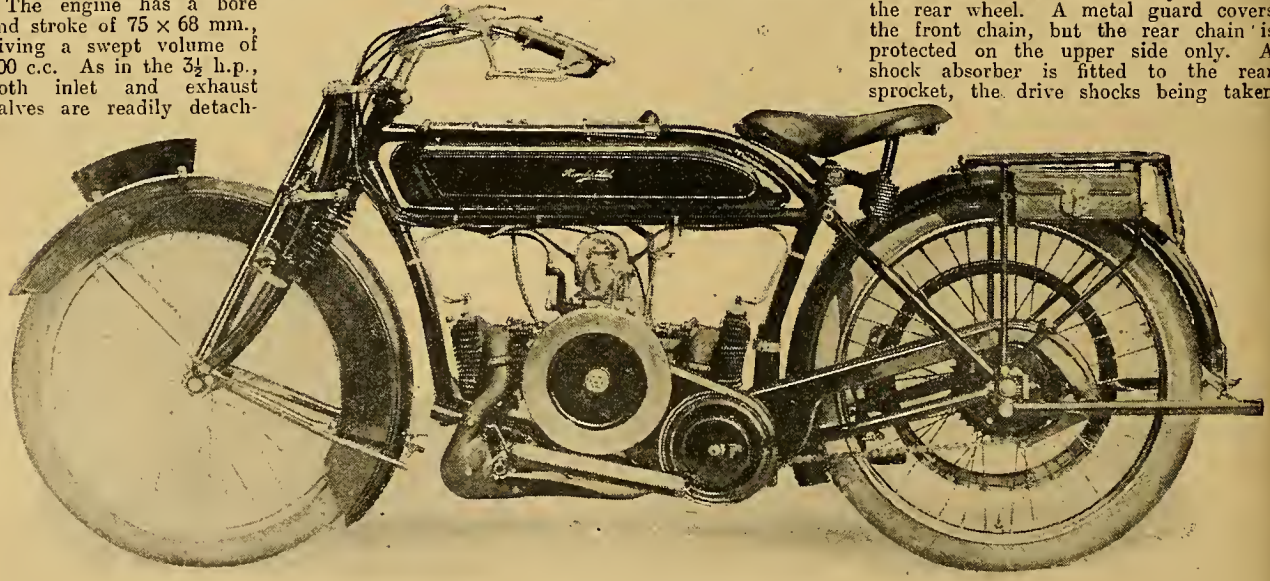
Dippers are affixed to the crank webs, and these collect oil in the hollow crank pins; subsequently this oil is thrown by centrifugal force to the white metal big ends, through a hole drilled radially in each crank pin.

The primary chain transmits the drive through a floating disc Ferodo clutch to a three-speed countershaft gear. This gear is a modified form of Humber gear box, the chief differences from that of the 3½ h.p. model being that it incorporates a neat kick starter, stub teeth gears, and both middle and low gears are now formed with the sliding member. This last modification was introduced in order to prevent loss of power due to oil churning of the constant mesh low gear wheels.

The final transmission is by chain to the rear wheel. A metal guard covers the front chain, but the rear chain is protected on the upper side only. A shock absorber is fitted to the rear sprocket, the drive shocks being taken



The new 4½ h.p. flat twin Humber, fitted with an engine of 75 × 68 mm = 600 c.c.

New Models.—

by a series of coil springs and the rebound by rubber blocks.

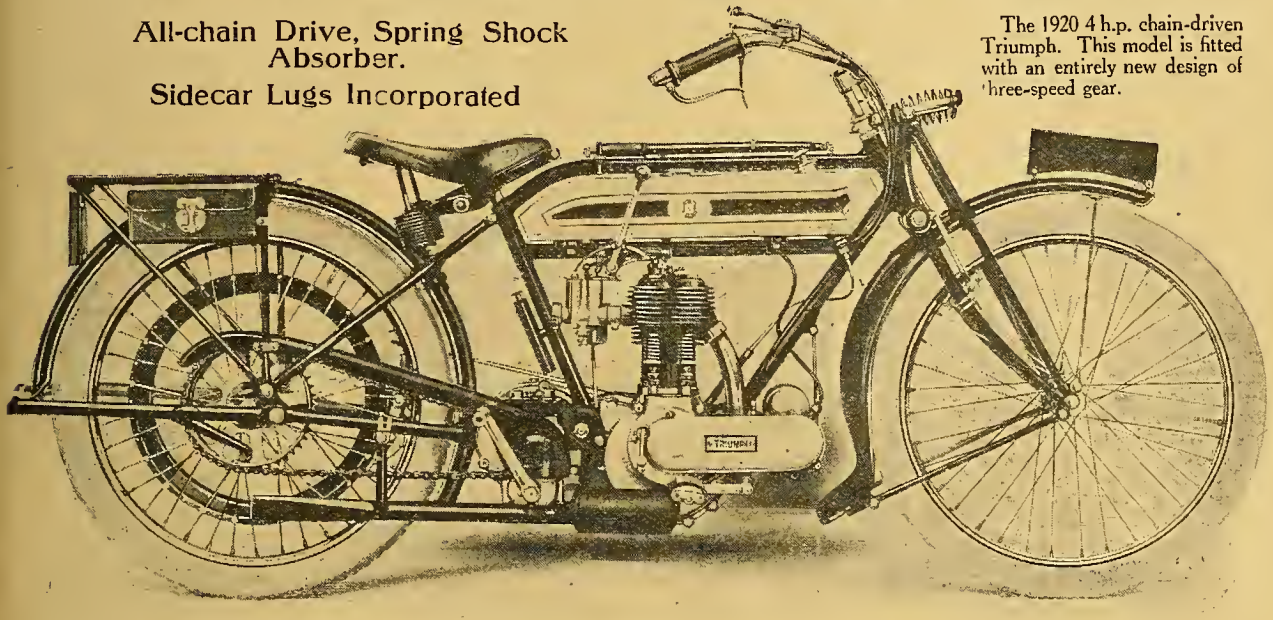
It should be mentioned that the rear wheel is very quickly detachable, the chain and brakes being undisturbed by the operation. A hinged rear guard facilitates wheel removal or tyre repairs.

The specification includes a Claudel M.I.A. automatic carburetter, E.I.C. magneto, and 26 × 2½in. Dunlop tyres. A Millford Corvette sidecar is attached at four points, and forms a roomy and comfortable conveyance for the passenger. The finish is in black and gold, and is very smart and serviceable.

On the road, we found the engine was extraordinarily quiet and smooth running, and the gears also were silent and easy to engage. The new model, with its 2¼ gallon petrol tank, is undoubtedly a very attractive medium-powered sidecar machine, and will draw many admirers at Olympia.

THE CHAIN-DRIVEN TRIUMPH MODEL.

All-chain Drive, Spring Shock Absorber. Sidecar Lugs Incorporated



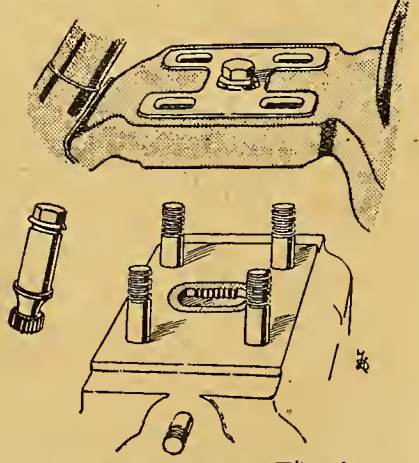
The 1920 4 h.p. chain-driven Triumph. This model is fitted with an entirely new design of three-speed gear.

IT has long been an open secret that the Triumph Cycle Co. contemplated an all-chain driven model. Nine months ago we were permitted to make an extended trial of one of the early experimental models, which, we may say, demonstrated the advance made in single-cylinder machines for sidecar work. To a certain extent the firm showed their hand by entering machines of this type in the A.C.U. Trials—in which, by the way, the Triumph was the only single-cylinder sidecar machine to gain a gold medal. With characteristic caution and thoroughness, the Triumph Co. elected to try out every detail of the new model by continued and strenuous road tests before deciding to place it before the public as a finished article, and it was only on Monday last that the press were given an opportunity of studying the final design.

The 4 h.p. engine, which has already earned an enviable reputation for reliability and pulling power, both under strenuous war conditions and in everyday use, remains unaltered, save for special bosses on the crank case to provide fixings for the chain case. It is in the transmission that the most important features lie, and these features are so pronounced that they are worthy of detailed description.

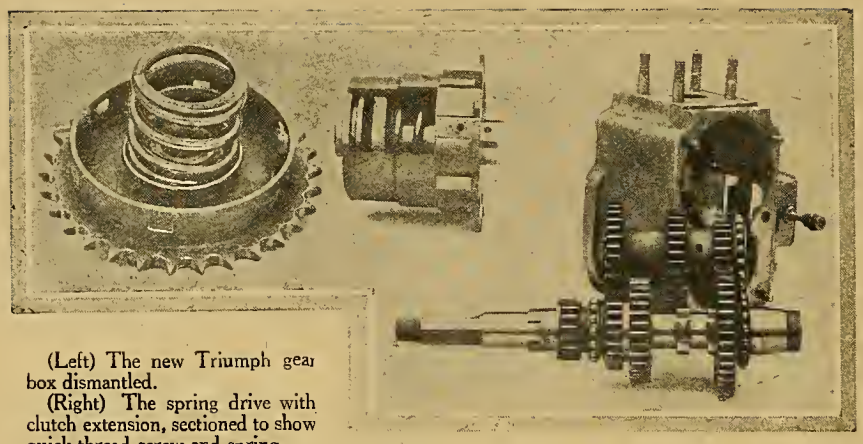
First of all the primary chain is enclosed in a special oil-tight case made of aluminium castings, held together by a series of studs. This case is fed with oil through a hollow stud in the lower part of the gear box, the oil being filtered through a gauze strainer before reaching the case. An overflow is provided to prevent an undue accumulation of lubricant, and a vent to avoid the possibility of air pressure due to heat.

Within the driven sprocket lies a disc clutch made up of seven pen steel and seven phosphor bronze plates held in contact by a powerful coil spring, the pressure of which can be released in a most ingenious manner.



Micrometer adjustment for Triumph gear box. By turning the toothed plug, which acts on a rack in the top of the gear box, a fine adjustment is provided for the front chain.

Between the gear box and sprocket lies a fixed three-faced cam, engaging with which are three feet on a rotatable collar, the movement of which is controlled by the clutch lever. A movement of the clutch lever thus causes the feet, and, consequently the collar, to rise on the cams, and thus, through a suitable thrust race, to force outwards a clutch withdrawing flange. This flange is fitted with three short pegs, which pass through the flange of the chain wheel and press against the clutch spring thrust race. By this means, the pressure on the clutch plates is relieved before any lateral motion of the chain wheel takes place. So much for clutch actuation; but the most interesting feature of the transmission lies within the diameter of the clutch spring, for the drive is not taken directly from the plates to the gearshaft, but passes from an extension of the inner clutch member through a quick-thread screw to a bronze member suitably and slidably mounted on the gearshaft. This bronze member is normally pressed outward by a coil spring, but any sudden snatch, such as is caused by an engine pulling at slow speeds, causes the screwed member to be forced inwards against the action of the spring, thus permitting a certain amount of relative motion between the two screwed parts. In practice, this device forms a most efficient shock-absorber, and, though difficult to describe, is extremely simple and effective in action.



(Left) The new Triumph gear box dismantled.
(Right) The spring drive with clutch extension, sectioned to show quick thread screw and spring.

There is nothing to go wrong, and should the spring break (a most unlikely occurrence), the owner would be left with a rigid drive and could continue on his way until the replacement could be conveniently carried out.

The new Triumph gear box is a fine piece of work, the layshaft being of large enough diameter to permit the kick-starter spindle to pass through the inside. It is formed in one piece with all the gear wheels, and runs on large diameter caged ball bearings. Similar, but smaller, ball bearings support the mainshaft and top gear wheel, the shaft passing through a long hardened steel bearing in the gear wheel. A sliding member, composed of the low and middle gear wheels, slides on the mainshaft, which is suitably castellated. The high gear is engaged by the usual type of dog jaws. Middle gear is engaged through meshing the two spur wheels as in car practice, and low gear is engaged in the same manner, though, between middle and low, there is an interval in the castellations, so that the sliding member is free to revolve on the shaft.

Easy Gear Changing.

Another feature of the gear box is that when the gears are engaged there is practically no "back lash" in the dogs. This, of course, would be impossible if provision was not made for "centring" the sliding member before final engagement. This is done by means of a set of dogs having a great deal of clearance through which the dogs on the sliding member pass, thus being brought into direct line with the driving dogs for final engagement. This feature renders the gear box practically foolproof.

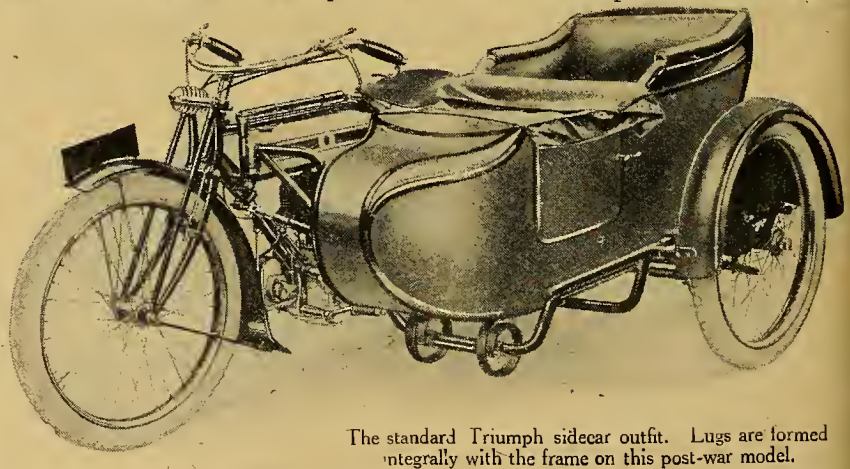
Primary Chain Adjustment.

The final drive is brought across to the right-hand side of the machine so as to be clear of the sidecar for inspection, and this chain is protected only on the upper side. The whole box is held up to the bottom bracket by four studs, and a particularly neat micrometer chain adjustment is provided. As previously mentioned, the kick-starter shaft passes through the centre of the layshaft, and a full gear wheel on the end meshes with a smaller pinion dogged to the chain wheel; thus the kick-starter operates directly and not through the clutch. The ratchet gear is positive and most ingenious, and the teeth are automatically tripped out of action when the starter pedal is returned to the normal position.

Integral Sidecar Lugs.

For the first time sidecar lugs are incorporated in the Triumph frame, and a beautifully finished Gloria sidecar, with spring suspension wheel, can be obtained with the machine, in combination form. At present, all Triumph models will be sold with the existing type of spring fork, but the enclosed spring type previously described in *The Motor Cycle* of April 24th, 1919, will be standardised as soon as production facilities admit. In addition to the above model, which will sell at £110 solo, and £154 with sidecar, the well-known chain-cum-belt model, with Sturmey-Archer gear, can be obtained for £97 solo, or £141 with the same type of sidecar.

The Triumph Junior (two-stroke) remains unaltered, and will sell at £63. In addition, a 3½ h.p. competition machine is on the stocks, but this will not be available for the public for several months.



The standard Triumph sidecar outfit. Lugs are formed integrally with the frame on this post-war model.

Electric Lighting for Motor Cycles.

A Noticeable Tendency. Will Combined Lighting and Ignition be Standardised?

THERE is every promise that before very long electric lighting will be as general on motor cycles as it is on present-day cars. We have already published details of several dynamos suitable for motor cycles, and elsewhere in this issue we are able to give advance particulars of another combined ignition and lighting unit which, being practically the same size as a conventional magneto, is particularly suitable for solo machines of even the smallest type. There are others, including one which will sell at a figure in the neighbourhood of £5, and another, with lamps and accumulator complete, for about £12 10s. So, provided these cheaper outfits prove to be reliable, there will shortly be no reason why every motor cyclist, if he so desires, should not have the conveniences of an electric lighting set, which at present is regarded more as something only the most opulent class of motor cyclists can afford.

Unquestioned Advantages.

Only those who have used an efficient dynamo lighting set on a motor cycle can fully appreciate its great convenience and cleanliness. Practically every car manufactured in this country and in America is catalogued with electric lighting equipment, and most of the motor cycles produced in the U.S.A., too, are so equipped. In this connection, it is interesting to know that a scooter and an auxiliary motor attachment are fitted with a magneto of the flywheel type from which current is available for lighting purposes. Therefore it is not unreasonable to expect an electrical unit on similar lines ultimately to find favour with designers on this side of the Atlantic.

At the present time there are many riders who look askance at electrical equipment, especially when it is combined with the ignition, but little need be feared on the score of unreliability, especially with some of the later systems which do not depend on the storage batteries for their efficiency.

Humber

At Olympia Stand No. 85.

The 4½ h.p. Humber Motor Cycle exhibited at Olympia has a flat twin cylinder engine, as in the 3½ h.p. model, but it should create a greater demand, because it is constructed for sidecar work as well as solo, whereas the 3½ h.p., though it did splendid service for riders with combination attached, was generally recognised as a "solo machine."

There is ample margin of power reserve in sidecar work with the 4½ h.p. Humber, and among other decided advantages note particularly these :—

A very efficient silencer.

Specially constructed frame to allow of easy removal of cylinders.

A kick-starter, in place of the handle-starter used on the 3½ h.p.

The 4½ h.p. model has been severely tested and proved thoroughly reliable, as well as economical in running.

It will be staged at Olympia, November 24th-29th, both as solo and with attractive and comfortably-sprung sidecar.

HUMBER, LIMITED.

Head Offices and Works:

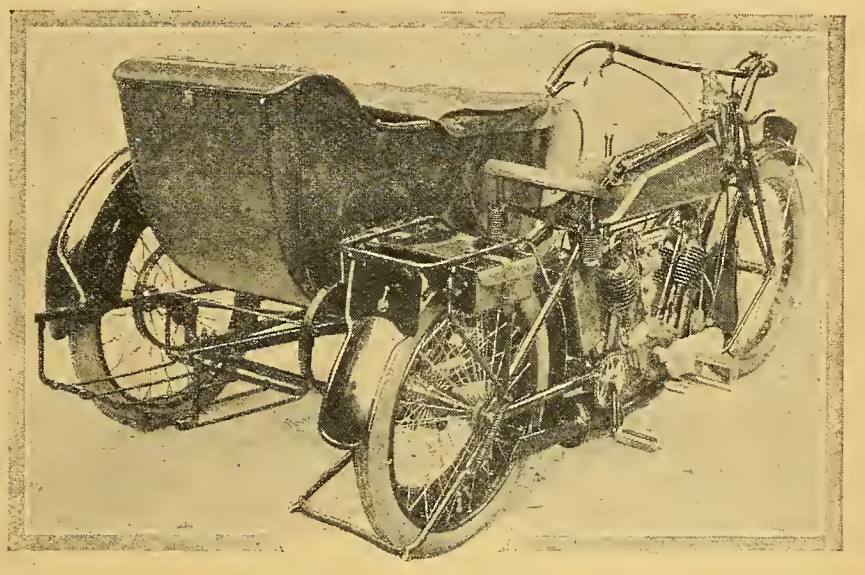
COVENTRY.

The 7-9 h.p. Rudge Multwin.

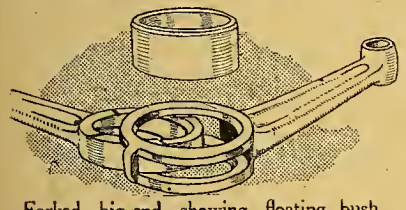
50° V Twin Overhead Inlet Valve Engine, Multi Gear. A Design largely based on Standard Rudge Practice throughout.

THE twin-cylinder Rudge engine was first planned some little time before the war, and is now definitely announced as one of the range of models offered to the public during the 1920 season.

To those riders who favour the infinitely variable type of belt transmission, the new engine will make a special appeal, since the necessary limitation of the lower gears with this form of drive has rather ruled out the small Rudge models for heavy sidecar work in mountainous districts. The larger engine, therefore, supplies the extra power which is desirable, and, being of the full 998 c.c. capacity, should answer every requirement, and withal, may be expected to have more than ordinary speed, by virtue of the 3½ to 1 top gear.



A powerful sidecar outfit. The 7-9 h.p. Rudge Multwin, which is designed on exceedingly graceful lines.

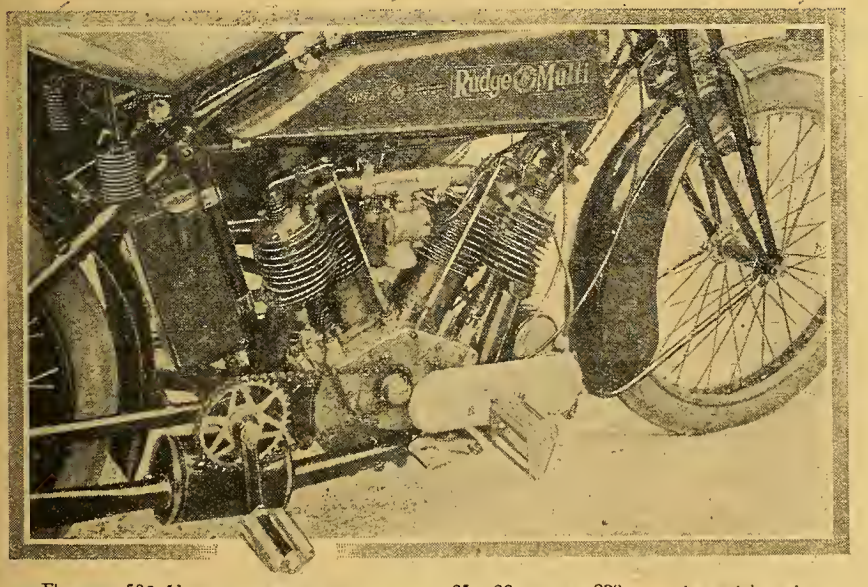


Forked big-end showing floating bush which runs on roller bearings on the crank pin. Note the off-set connecting rod.

The engine, so far as externals go, and excepting the *désaxé* cylinder setting, is at once recognised as being characteristically "Rudge," for the chief details are similar to those of the well-known single model; the inlet valves being placed above the exhausts in detachable domes. A very clean exterior characterises the crank case, which is an aluminium casting, entirely free from ridges, designs, or lettering of any kind likely to hold dirt or interfere with ease of cleaning.

Roller Bearing Connecting Rods.

A T shaped induction pipe, which telescopes directly on to the inlet dome stubs and is there secured by clips, carries a vertical model Senspray carburetter, which depends between the cylinders.



The new 50° V-twin engine, bore and stroke 85 × 88 mm. = 998 c.c. A special vertical Senspray carburetter is fitted, and a chain-driven magneto.

Top feed to the float chamber is employed, and the air intake points downwards.

Neat valve lifters, similar to those of single-cylinder models, operate by means of small levers under the tappet heads, and the usual Rudge pedalling gear, rotating the engine through a positive acting friction device on one of the half-time wheels, is retained for starting purposes.

Rudge engines are noteworthy as being amongst the few made which are fitted with roller bearings in both big and small ends of the connecting rod, and this practice is followed in the twin-cylinder model. The application of rollers to the crank bearing of a V twin, in which both rods work on a common pin, is not without its difficulties, and the usual side-by-side arrangement was not considered perfect. In order to eliminate the short couple, which would otherwise exist, a peculiar construction of forked rods is used; the single rod works inside the double one, and the latter has a small stiffening piece bridging the two sides of the fork. A steel bush passes through the eyes of the rods, and is a floating fit in both; this bush bears on rollers which run between it and the crank pin, and these are the full width of the combined big end. The workmanship in this part is exceptionally good, ample provision being made for lubrication.

T.T. Frame Design.

Oil is carried in the tank behind the saddle tube, and delivered to the engine through a foot operated pump. The latter discharges through a short pipe into the crank case in such a way that each fresh charge of oil is injected between the two flywheels directly on to the big ends.

A type of frame popularised on the Rudge T.T. models is used on the 7-9 h.p. twin; it has a sloping top tube, and

The 7-9 h.p. Rudge Multwin.

has a large tank holding a full two gallons of spirit. In other respects, also, the Rudge specification is followed. It is satisfactory to note that all the lugs employed in the frame are steel stampings, and that these, together with the connecting rods, flywheels, and other parts capable of being stamped, are manufactured throughout in the Rudge works.

The well-known Multi gear, with free engine clutch on the engine-shaft, is used, and this, in conjunction with the large reserve of engine power available, should render satisfactory service, even when a heavily laden sidecar is being towed; incidentally, the machine is neither too weighty nor too unwieldy for solo use, and should be an ideal fast touring mount.

The detail work is well carried out, and all the refinements associated with this make are included, such as screw-down greasers to the fork bearings, spring-up rear stand, hinged rear number plate, and mudguard extension, drop pedal footrest, and celluloid finished handle-bars, hubs, and gear lever; 650 × 65 mm. light car tyres are fitted on extremely heavy round base rims.

The M-L Lighting and Ignition Unit

A Novel Electrical Machine generating Current for Lamps and Ignition.

MUCH attention of late has been devoted by manufacturers of electrical ignition apparatus to the incorporation in one machine of suitable means whereby not only the functions of the magneto are performed, but also the generation of lighting current is made possible.

The latest device of this nature which we have had the opportunity of inspecting is the M-L lighting and ignition unit, which, while being neither a combination of magneto nor dynamo as ordinarily known by the motor cyclist, yet embodies the characteristics of each and performs in the dual capacity.

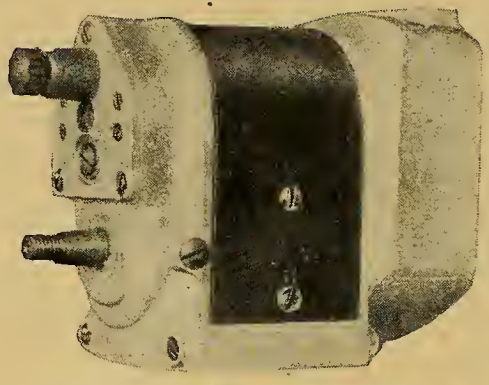
This particular instrument is no larger than a pre-war single-cylinder magneto, excepting for the end extension, which forms the housing for the primary circuit interrupter and its reduction gear, and the weight is only slightly in excess of a standard magneto.

Since it is still in the experimental stage, and production of the present model has not yet been decided upon, precise details of the interior mechanism must be withheld, but its action may be briefly described.

Small Accumulator.

The apparatus consists essentially of the following parts: a low-tension generator running at one and threequarter engine speed, a stationary transformer, and a contact-breaker running at half engine speed working in conjunction with a wipe contact device which short-circuits the transformer except at the moment when the sparking current is required.

A battery is connected to the circuit, but it is not essential to the working, and its failure or removal in no way interferes with the ignition or lighting; it is merely used to steady the lights and



Exterior view of the M-L lighting and ignition unit. In size it is little greater than the ordinary magneto.

to provide illumination when the engine is stationary, hence its dimensions may be kept quite small. Another advantage of this system is that, owing to the use of permanent magnets, the voltage from the generator fluctuates surprisingly little with varying rates of engine revolutions, and that charging of the battery commences at the lowest speeds, thus dispensing with the need for any other control than the simplest form of mechanical cut-out.

A brief explanation of the working of the system will be of interest to the technically inclined reader, and its simplicity will be evident from the diagram herewith.

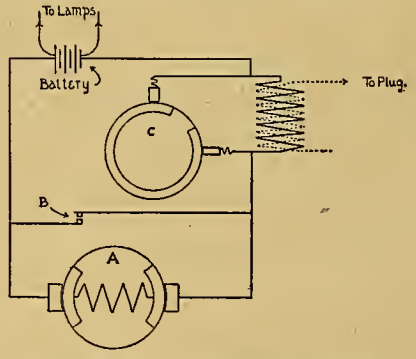


Diagram showing the circuits. The working principle is very simple and can be readily understood by reference to the explanation in the text.

The generator A, driven at one and threequarter engine speed, is an H-section armature, running between the poles of a permanent magnet of ordinary magneto type. A simple two-segment commutator enables a continuous current to be collected by two dynamo pattern brushes. At B are two platinum points through which the generator winding may be short-circuited, and these are closed by a cam fixed to C, and rotating at half engine speed. C is an interrupted segment through which, by means of suitable brushes, the primary winding of the high-tension transformer may be either short-circuited or brought into the path of the current from the generator to the batteries.

Now let us consider the action. With the segment C in the position shown, and the contact points open, the current generated by A passes directly to the batteries or lamps. When the instant in the cycle of operations for the requirement of the spark approaches, the interrupted portion of C comes under one of the brushes, thus bringing the transformer primary into series with the generator, and the cam closes the platinum points, and shorts the generator windings. A primary current of great intensity is built up, and when the armature reaches the maximum position the points separate, and the inductive flow rushes through the circuit by way of the transformer primary, and a high-tension current is induced in the secondary winding, and the spark occurs at the plug.

Steady Voltage.

It will be seen that the ignition in no way depends on the battery; indeed, we have seen a standard single-cylinder outfit running on this apparatus with the battery disconnected, and the fluctuation of the lights was remarkably small, even when the engine was alternately opened out and shut off to a mere tick over.

We were altogether much impressed by our preliminary inspection of this unit, and can congratulate its designer on his achievement, which, without being freakish, entirely departs from the beaten track, and at the same time avoids the weaknesses of some of the earlier efforts to achieve the same result.

A £100 CYCLE CAR.

FOR years manufacturers have been fascinated by the £100 mark to which to produce a four-wheeled runabout, and it must be said that, even in the days when the purchasing power of money was twice as much as it is to-day, very few succeeded. It is, therefore, all the more interesting to know that a serious attempt to market a £100 two-seater is being made by a Golders Green firm for 1920, and, from particulars to hand of the preliminary model, a reasonable measure of success appears to be in sight. The machine will be known as the Challenge, and its specification includes a 6 h.p. engine, two speeds, and transmission is by a single chain and belt. A sporting two-seater body is fitted.

The Triumph Directorate.

Lieut.-Col. C. V. Holbrook, A.S.C., late Director of Mechanical Transport and Controller of the Disposal Board, has been elected to a seat on the board of the Triumph Cycle Co., Ltd., Coventry.

Brussels Show.

A motor car and motor cycle show will be held at Brussels from January 10th to 18th inclusive. The exhibits are confined to Belgian manufacturers of cars, motor cycles, cycles, and accessories.

A Meet of M.M.G.S., 26th Battery, at Olympia.

Mr. Southcombe May, hon. secretary, Motor Cycling Club, and formerly sergeant No. 3 Section, 26th Battery, M.M.G.S., writes suggesting that old boys of the M.M.G.S.—particularly of the 26th Battery—meet at Olympia. As the later batteries rode Clynos, the suggestion is that the meeting place be the Clyno stand on the Wednesday evening. Mr. Southcombe May has obtained permission of the Clyno Engineering Co., who fell in with the idea readily. We think the idea a good one, and no doubt many ex-Service men will be pleased to take this opportunity of meeting old comrades.

THE MOTOR CYCLE

SPECIAL OLYMPIA SHOW NUMBERS.

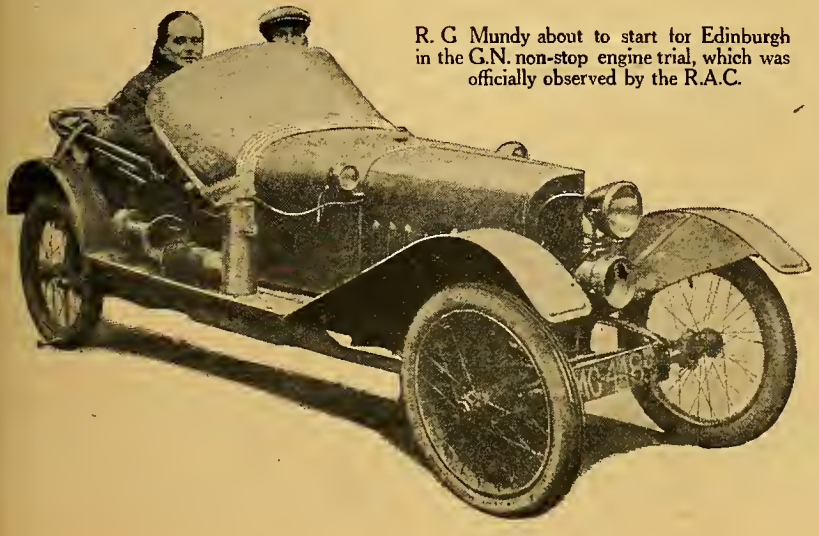
Nov. 20th.—This issue will contain a forecast of the Exhibition, particulars of new models, also plan of the Show and list of exhibitors. This number will be on sale at the Show.

Nov. 27th.—Full Show report. This number will also be on sale at the Show.

Dec. 4th.—Review of sidecars, accessories, tyres, etc. Impressions of the Exhibition.

The Institution of Automobile Engineers.

Advantage is to be taken of the presence of the motoring world in London during Olympia Show week to hold a reception of members of the Institution of Automobile Engineers. The idea is to afford members an opportunity of meeting the council and each other in a more sociable manner than is generally possible at the monthly meetings. The reception takes place at the Kensington Town Hall, to-day, at 3.30 p.m. Speeches will be followed by tea and music.



R. G Mundy about to start for Edinburgh in the G.N. non-stop engine trial, which was officially observed by the R.A.C.

Special Features.

THE PASSENGER OUTLOOK.
PASSENGER MACHINES FOR 1920.
SIDECAR HINTS.

French Driving Licence.

There is just a possibility that the driving licence *(permis de conduire)* may be abolished in France. A committee sat recently in Paris to consider the question.

To the Rescue!

The Beckenham fire brigade's motor cycle fire outfit rendered first-aid at a local fire last week. The tricar, two firemen, and chemical extinguisher speedily overcame the outbreak.

Black and Gold.

The black tank, lined with gold, is increasing in numbers and popularity, and quite an array of machines so finished will be staged at Olympia. Does this mean that eventually the coloured tank will disappear? At one time the aluminiumised tank was recognised as *the* finish, but it now takes second place.

The R.A.C. 5,000 Miles Benzole Trial.

The two Triumph motor cycles which have been undergoing a strenuous trial on benzole finished their 5,000 miles a little after three o'clock on Wednesday, the 5th inst. Both machines were, naturally, covered with mud, as the weather conditions during the latter part of the trial were exceptionally bad. Neither had experienced any trouble whatsoever. The dismantling of the cylinders of both machines will take place at Queensberry Mews, South Kensington, London, S.W., under the official observation of the A.A. and M.U., and the report issued very shortly.

The Annual General Meeting of the Motocycle Club of France.

At the recently held Annual General Meeting of the Motocycle Club of France, the Marquis de Nareinty-Tholozan was elected president. The new president was a captain in the French Aviation Corps during the war, and is an old and active motor cyclist. Several vice-presidents were elected, and also the competitions and touring committees. Contrary to the practice usually followed in English clubs, the competitions committee consists of several members of the trade and several trade riders. At the end of the meeting M. A. W. Polak, the former president of the club, was elected honorary president. M. Polak has always been a keen worker on behalf of the M.C.F., and is representative in Paris of Messrs. Brown Brothers, Ltd., and the Birmingham Small Arms Co., Ltd.

Passenger Machines of 1920

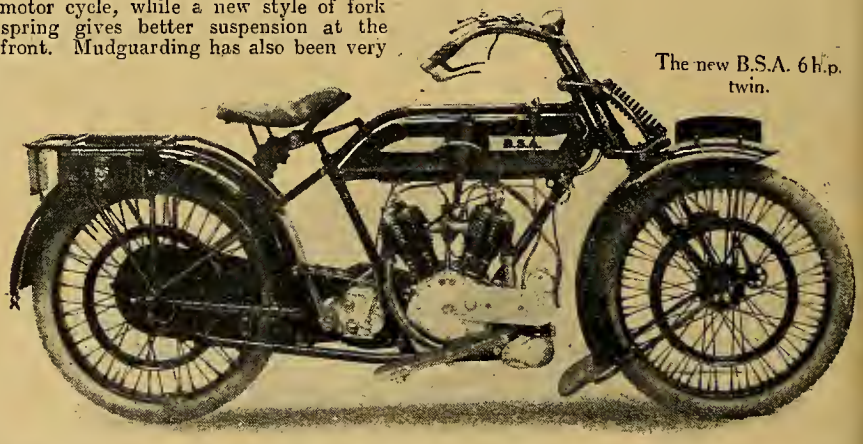
Anyone who spends but a few hours on a main road cannot fail to be impressed with the number of passenger motor cycles and runabouts that pass. Before the war the greater number of motor cycles were ridden solo, but the passenger machine has been steadily increasing in popularity until at the present day there are comparatively few motor cycles designed for solo work only, excepting, of course, lightweight two-strokes and a few four-strokes.

The reason is not far to seek. The increase of prices and decrease in the value of money has driven many car owners to economise, and added to this a very large section of the community has come into touch with things mechanical during the last five years, and has been bitten with the fever, as might be expected. Undoubtedly, light three and four-wheelers are the cheapest form of travel for two, and the freedom of the road has an attraction which must be experienced to be realised. A week end in the country is an easy matter for the owner of a modern motor cycle, and if he is a family man it is wonderful how many of the family can be accommodated on a motor cycle and sidecar. Only the future can show whether the new light four-wheelers will encroach upon the enormous demand for motor cycles and sidecars, but whether or not this will be the case, we shall continue to encourage all types of economical motor vehicles which are of real interest and likely to appeal to the motor cycle public—sidecar outfits, three-wheelers, or four-wheelers, it matters but little to the man of limited means, provided that the price approximates to that of a motor cycle and sidecar and the article is mechanically sound.

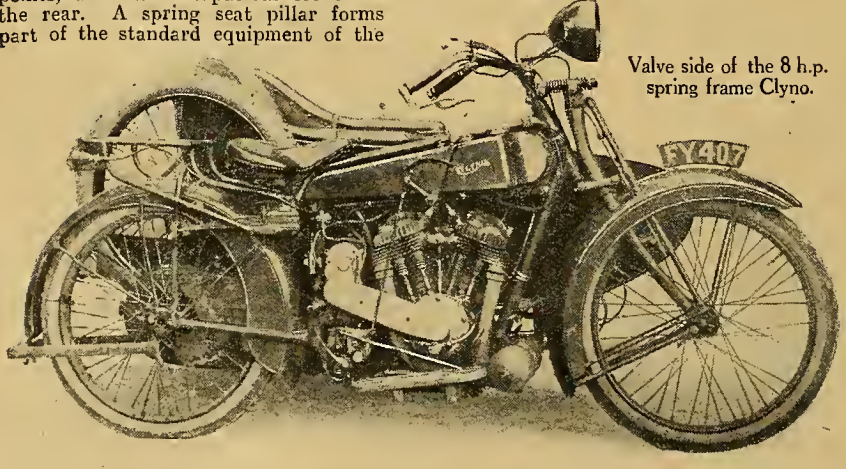
THE B.S.A. ENTERS THE TWIN FIELD.

UNDOUBTEDLY one of the most popular machines of 1919 has been the B.S.A. single-cylinder motor cycle, and its success in the big competitions was crowned by the winning of the team prize in the recent A.C.U. Six Days Trials. For 1920 the range of passenger machines will include the 4¼ h.p. chain drive machine at £95, a chain-cum-belt 4¼ h.p. model at £93, and the new 6-7 h.p. twin model described in *The Motor Cycle*, October 2nd. The price of this machine, with 28 × 3in. tyres, is £130, and £38 for sidecar.

This latter model has a mechanically lubricated twin engine of 76 × 85 mm. (770 c.c. capacity), having roller big ends, and the general specification includes three-speed gear, all-chain transmission, enclosed in neat but substantial cases, and interchangeable wheels. The sidecar is particularly roomy, attached at four points, and has a capacious locker at the rear. A spring seat pillar forms part of the standard equipment of the motor cycle, while a new style of fork spring gives better suspension at the front. Mudguarding has also been very efficiently carried out, enormously wide domed guards being fitted.



The new B.S.A. 6 h.p. twin.



Valve side of the 8 h.p. spring frame Clyno.

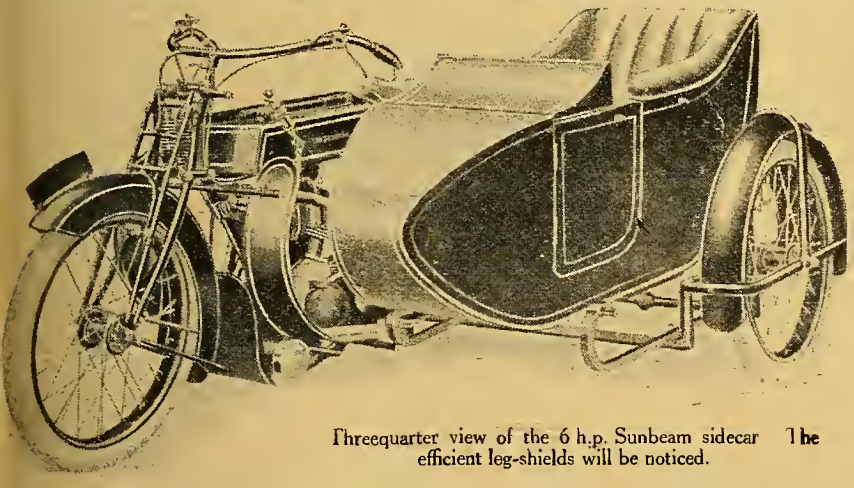
THE CLYNO SPRING FRAME MACHINE.

Long anticipated as one of the outstanding machines of the few new designs produced since the end of the war is the 8 h.p. spring frame Clyno, which was fully described in *The Motor Cycle* so far back as February 20th this year. Difficulties in changing over from war work, however, have held up the production of the machine, but there is now every promise that deliveries will commence early next year. Having exceptionally high ground clearance, rear wheel sprung by laminated springs, and 28in. × 3in. wheels, the Clyno is in every way a colonial model such as is demanded by overseas' buyers as well as a large percentage of motor cyclists in this country. The engine has a bore and stroke of 76 × 102 mm. respectively, the total capacity being 925 c.c. The cylinders, which are set at 42°, have heads and barrels which are quickly detachable by removing one nut and slackening off another. Lubri-

cation is by mechanically-driven pump, and a hand pump is also fitted, with which, by means of a two-way tap, the driver may deliver a charge of oil to either engine or gear box. An efficient shock-absorber on the engine-shaft renders the drive particularly smooth. The chain cases are of cast aluminium. The illustration shows the machine fitted with the Lucas Magdyno and lamp equipment.

AN 8 H.P. TWIN WITH OUTSIDE FLYWHEEL.

If only on account of its outside flywheel, the 8 h.p. twin Blackburne stands in a class by itself. For many years the Blackburne single, in various forms, has been regarded as a prototype of the engine of the future, but the big twin, embodying the same features, *i.e.*, detachable heads, plain bearings, and outside flywheel, is a proposition comparatively new to the present-day motor cyclist. It made its public debut in the London-Edinburgh run last Whitsuntide, and all who saw it were impressed by its smooth and silent running.



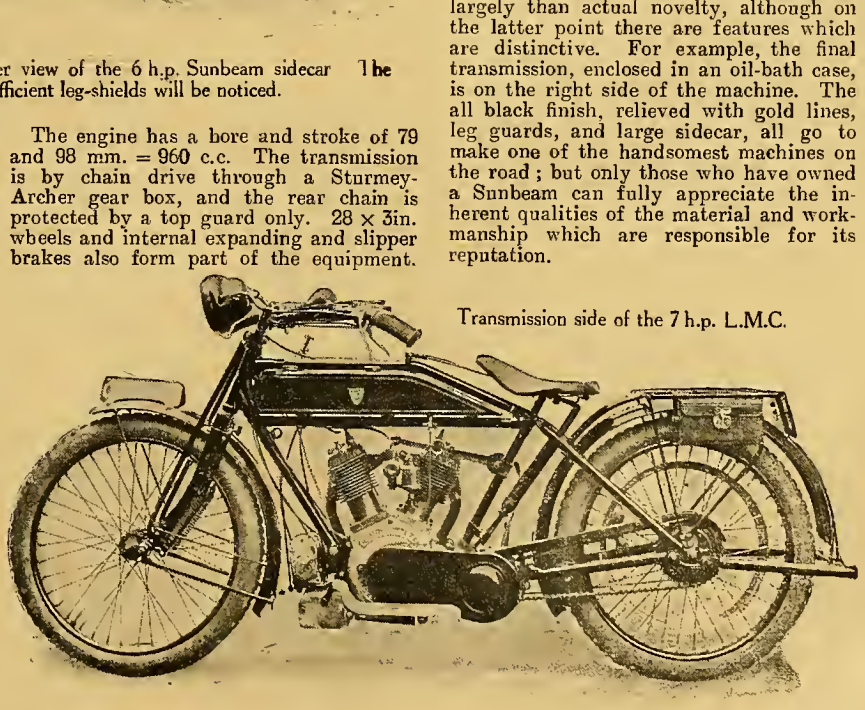
Threequarter view of the 6 h.p. Sunbeam sidecar. The efficient leg-shields will be noticed.

The cylinders are 85 × 88 mm. (998 c.c.), and the engine is placed sufficiently high in the frame to give ample ground clearance for overseas as well as home country requirements. The magneto is placed at the rear of the seat tube. Large in capacity, the sidecar is suspended on coil springs, and, in every way, the Blackburne twin is a most attractive machine of the de luxe type.

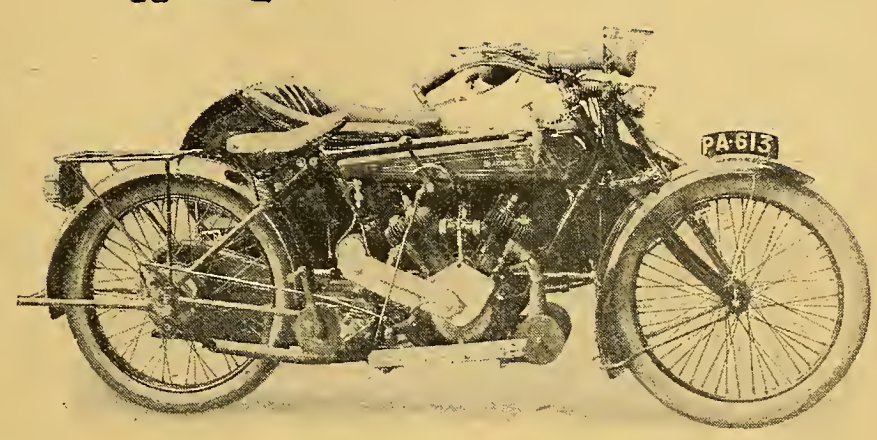
A LARGER L.M.C. TWIN FOR 1920.

Long stroke engines are coming into favour with designers of twin-cylinder power units; in fact, one may say that all the new designs of V twin engines are of this type. The new 7-9 h.p. L.M.C. is an example, and is a model embodying many features which will appeal to the sidecar owner at home and abroad. Among these may be mentioned the method of springing the driver's weight. The saddle is supported on a long leaf spring, pivoted at its forward end on the frame at a point about midway along the top tube. At its rear end the spring swivels on the top of a spring-loaded plunger, which is connected by tension rods to the footboards. In addition, the seat-pillar also contains a plunger with a roller head which bears upon the centre of the main frame of the saddle. Below this plunger are inserted springs of predetermined strength to suit the weight of each individual rider.

The engine has a bore and stroke of 79 and 98 mm. = 960 c.c. The transmission is by chain drive through a Sturmey-Archer gear box, and the rear chain is protected by a top guard only. 28 × 3in. wheels and internal expanding and slipper brakes also form part of the equipment.



Transmission side of the 7 h.p. L.M.C.



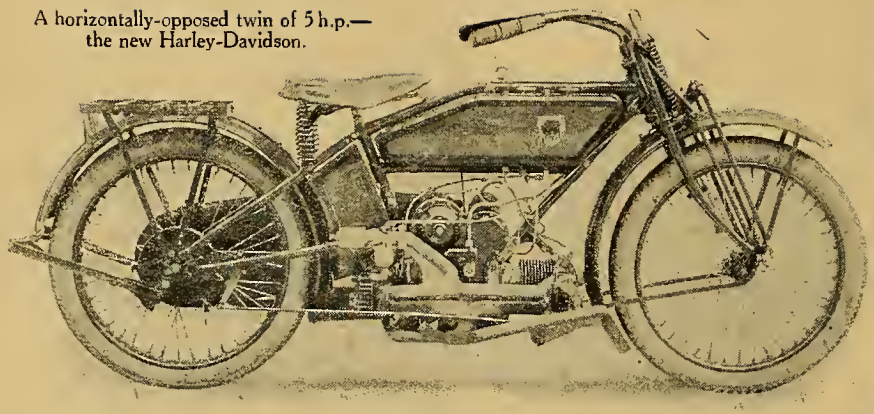
Valve side of the 6 h.p. Blackburne sidecar.

THE SUNBEAM PROGRAMME. 3½ AND 8 H.P. MODELS

Considering the success and popularity of the 3½ h.p. Sunbeam, both as a solo and sidecar machine, it is not surprising that it will again be marketed as one of the Sunbeam chief products. For next year, however, an improved front fork springing will be embodied, which comprises a single leaf spring, and is of particularly pleasing design. The Sunbeam sidecar for this model possesses several features which will interest visitors to Olympia. Incidentally, the way in which this engine pulls a sidecar over arduous trial routes is sufficient proof that the 500 c.c. unit will accomplish serious passenger work.

The 8 h.p. model remains practically unaltered—a handsome machine in the front rank of the world's motor cycles—in which refinement, quiet running, and general reliability figure more largely than actual novelty, although on the latter point there are features which are distinctive. For example, the final transmission, enclosed in an oil-bath case, is on the right side of the machine. The all black finish, relieved with gold lines, leg guards, and large sidecar, all go to make one of the handsomest machines on the road; but only those who have owned a Sunbeam can fully appreciate the inherent qualities of the material and workmanship which are responsible for its reputation.

A horizontally-opposed twin of 5 h.p.—the new Harley-Davidson.



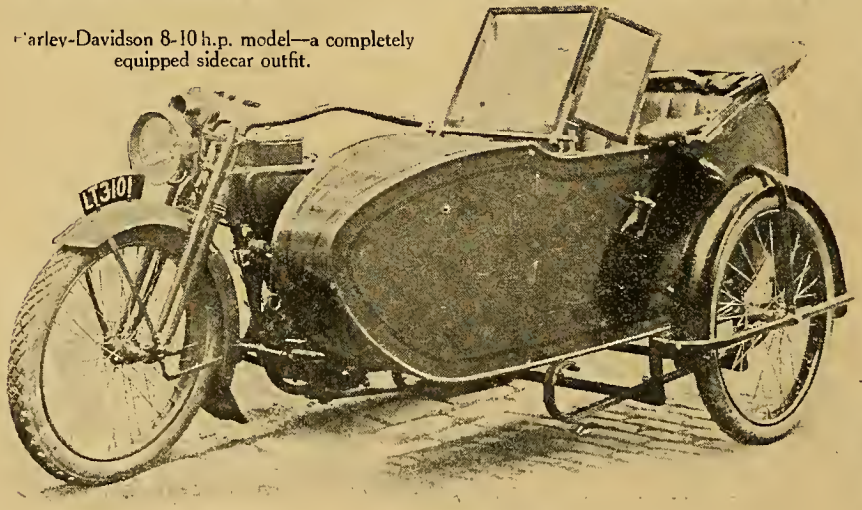
THE FLAT TWIN HARLEY.

Although designed as a solo mount, the new Harley-Davidson opposed twin is of a size used for sidecar work in this country, and as such it may have a strong appeal with British motor cyclists. It departs from conventional flat twin practice by embodying the gear box on the upper side of the crank case, hence the transmission case is somewhat long and disposed at an angle. The engine, which has a bore and stroke of 70×76 mm. respectively (584 c.c.), embodies several interesting features, including a cast aluminium manifold combining the exhaust pipes and the heated inlet pipe, staggered valves on the side of the engine, and a kick-starting device with its mechanism behind the flywheel and enclosed by the shield covering the latter. Three speeds are provided by the gear box. This machine was fully described in *The Motor Cycle* for August 14th. The 7-9 h.p. Harley-Davidson has become one of the most popular "big twin" sidecar machines.

The capacity of the engine is 988 c.c.; overhead inlet valves, mechanical lubrication, and combined lighting and ignition are among its many features.

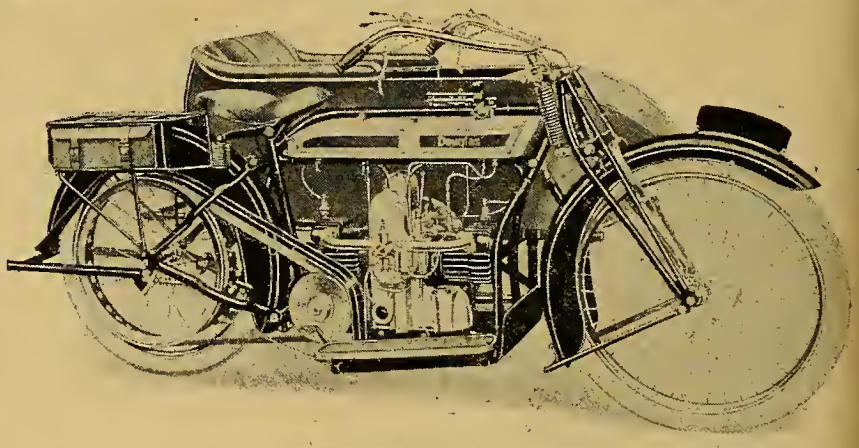
Amongst the many details connected with the Harley-Davidson which will appeal to the practical rider, an outstanding feature is the interconnected clutch and gear control mechanism whereby the gears cannot be changed until the clutch is disengaged.

Harley-Davidson 8-10 h.p. model—a completely equipped sidecar outfit.



A 4 H.P. OUTFIT. THE HORIZONTALLY-OPPOSED TWIN DOUGLAS.

Many lessons were learned by the makers of the Douglas machines during the war, and the experience gained from the use of the 4 b.p. outfit in military service is reflected in the latest models. While the engine remains almost unaltered, the frame and forks have undergone detail improvements from time to time, and now appear in a highly practical form. The spring forks have renewable bushings to the spindles, and screw-down grease cups are fitted, adequate oil grooves being cut in all the bearing surfaces. A round-cornered tank is now fitted, which greatly improves the general appearance. Mudguarding is very efficient, and a large underscreen is fixed beneath the footboards, and this is upturned at the front so as to stop the spray arising from the front wheel. Large toolbags are fitted into the sides of the carrier, and are of more sensible dimensions than those usually fitted to motor cycles. The Douglas sidecar is very roomy, and has a large receptacle for spares and equipment behind the back rest of the seat. A four-point chassis is used, the wheel axle is supported at both ends, and the body is carried at the rear on transverse springs. Amongst medium-weight sidecar outfits, the 4 h.p. Douglas is deservedly popular. Its controllability, due to the handle-bar operated clutch and the easily changed three-speed gear, together with the smooth running obtained from the chain-cum-belt transmission and the even torque of its engine, are extremely desirable features. In this connection also the mechanical lubrication must not be forgotten, since it absolves the rider from the trouble of oiling.



Transmission side of the 4 h.p. Douglas

THE 8 H.P. DOT.

Finished entirely in dark-red enamel, the Dot is particularly attractive, and examination of its mechanical details in no way belies the promise of its appearance. A J.A.P. engine, of 8 h.p., forms the power unit, and this is equipped with an Amac carburetter and E.I.C. magneto. All the standard features of this engine are retained, such as the adjustable tappets and the enclosed exhaust valve lifter. Beneath the magneto platform a large silencer is fitted transversely at the front of the engine, and two pipes lead from this to the rear of the machine.

Transmission is by chain throughout, a Sturmey-Archer gear box, fitted with kick-starter and the well-known Ferodo disc clutch, supplies the necessary gear reductions. Complete chain cases are not fitted, but a cover which encloses the primary chain and clutch is continued so as partially to enclose the rear chain and sprocket. The saddle fitted is an XI-All, and Saxon forks are used. Side-

car lugs are made integral with the frame, and the passenger attachment is thus firmly secured at four points. A roomy sidecar body, which is extremely well upholstered, is carried on four C springs. The chassis is of strong duplex construction, and the wheel is surrounded by a tubular framework in which the axle is supported at both ends.

THE 6 H.P. A.J.S.

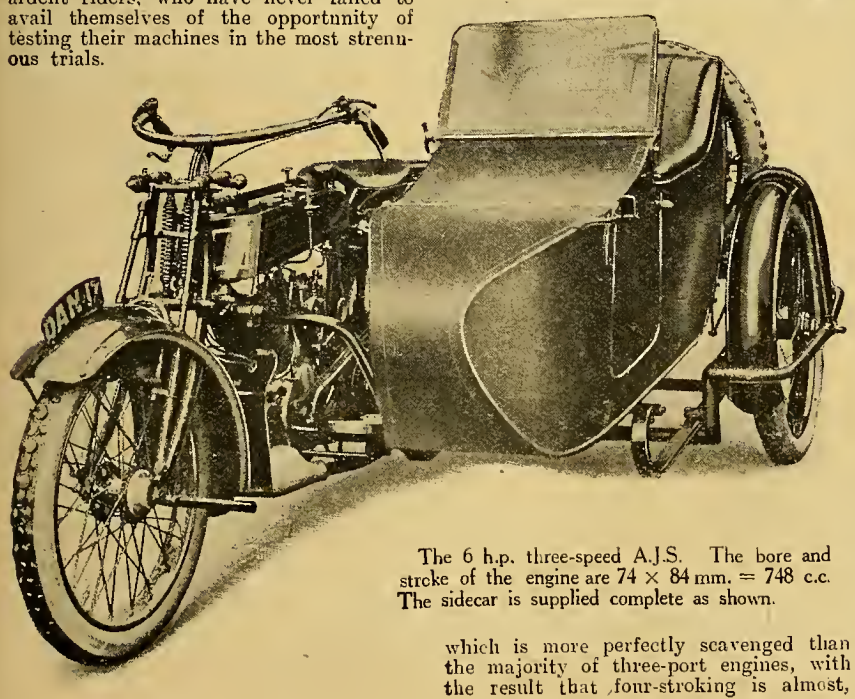
There is no doubt that among the "class" machines of 1919, the A.J.S. is one of the most important. It has been an exceedingly popular machine, and, since it was entirely redesigned early in the year, but few alterations will be found in the 1920 model.

Having detachable heads, the cylinders are 74×87 mm. (748 c.c.)—a size which before the war was most popular on account of its economy. On this account it is perhaps surprising that there are so few survivors; many of the makers hitherto fitting this size are now offering 8 h.p. machines.

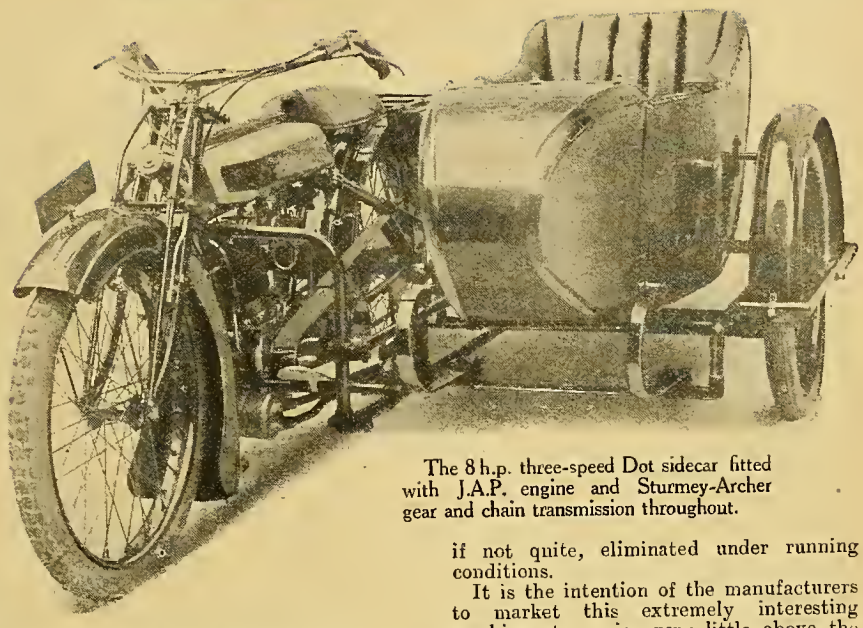
A.J.S. machines are noted for their quiet running, their large mudguards, quickly detachable wheels, and the good qualities of the sidecar, which is fitted with a glass screen and hinged dash as standard equipment. The interchangeable and quickly detachable wheels are shod with 700×80 mm. tyres, a spare being carried at the rear of the sidecar body, which also has a neat luggage platform sprung with it—a most desirable feature. A sprung seat-pillar is fitted, and an important feature is the lever on the rear stand by which the raising of the machine is rendered quite an easy matter.

Not only in finish, but in the practical nature of its detail mechanism, the A.J.S. reflects ripe experience and understanding of the motor cyclists' requirements.

This, no doubt, is the outcome of the fact that the principals of the firm are ardent riders, who have never failed to avail themselves of the opportunity of testing their machines in the most strenuous trials.



The 6 h.p. three-speed A.J.S. The bore and stroke of the engine are 74 × 84 mm. = 748 c.c. The sidecar is supplied complete as shown.



The 8 h.p. three-speed Dot sidecar fitted with J.A.P. engine and Sturmey-Archer gear and chain transmission throughout.

DUNELT BIG SINGLE TWO-STROKE.

The introduction of a 500 c.c. single-cylinder two-stroke engine by a large firm of steel manufacturers and engineers is a matter of great interest, especially to those who maintain that the two-stroke engine will eventually take as prominent a position among sidecar machines as with lightweight solo motor cycles. The machine to which we refer is the Dunelt, described in last week's issue, and which will be exhibited at Olympia on the stand of Messrs. Dunford and Elliott (Sheffield), Ltd.

By the use of a truncated piston, the designers of the Dunelt have succeeded in producing a large two-stroke engine which is more perfectly scavenged than the majority of three-port engines, with the result that four-stroking is almost, if not quite, eliminated under running conditions.

It is the intention of the manufacturers to market this extremely interesting machine at a price very little above the present-day price of the average lightweight.

THE G.L. 6 H.P. MACHINE.

A French motor cycle built largely of British components and conforming to British ideas of conventionalities, is the G.L., which was awarded a silver medal in the recent Six Days Trials. This machine will be imported by Messrs. Vivian Hardie and Lane, of Woodstock Street, W.1, and is manufactured by M. Georges Levy, of Argenteuil.

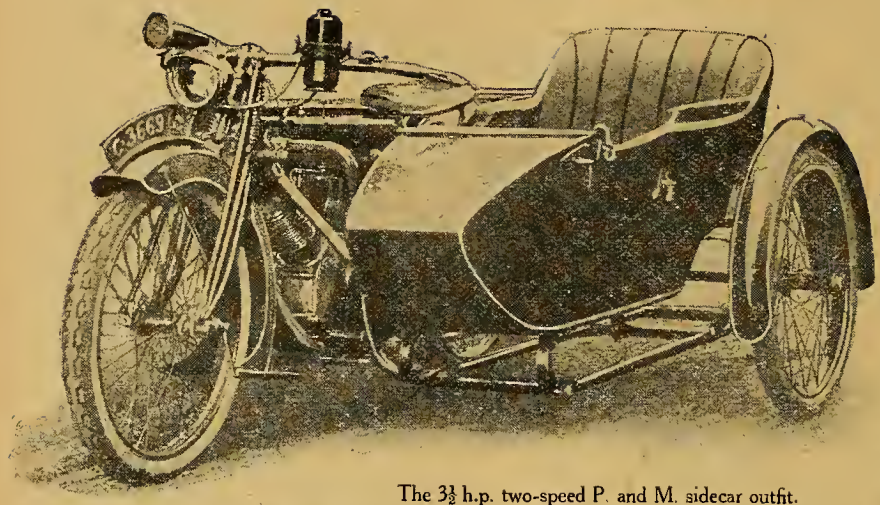
The G.L. is distinctive in appearance, and will make a strong appeal to riders on account of the neatness and refinement of its design. The engine fitted is a 6 h.p. J.A.P., which drives through a Sturmey-Archer three-speed gear box by means of chains. All wheels are detachable and interchangeable, and no tools are required to remove them. A spring saddle-pillar is one of the several features in its design, while a band brake on the engine-shaft is distinctly novel. The sidecar fitted is also designed by M. Georges Levy, and is extremely light and pleasing to the eye.

A 4 H.P. VERUS.

The makers of the Verus lightweight motor cycles will produce a single-cylinder dual purpose machine engined with a 4 h.p. Blackburne engine and fitted with a three-speed gear box.

THE P. AND M. SINGLE-CYLINDER MACHINE.

A machine which did good service in the R.A.F. as a sidecar mount, the 3½ h.p. P. and M., will appeal to the owner who appreciates a quiet running engine. The 1920 model, which was fully described in our issue for September 11th, has not undergone any startling alterations as regards design, but there are several improvements which help to keep the machine thoroughly up-to-date. The tank now slopes slightly at the rear, the kick starter is rendered more efficient and is placed further back, and a newly designed expanding brake has been added.



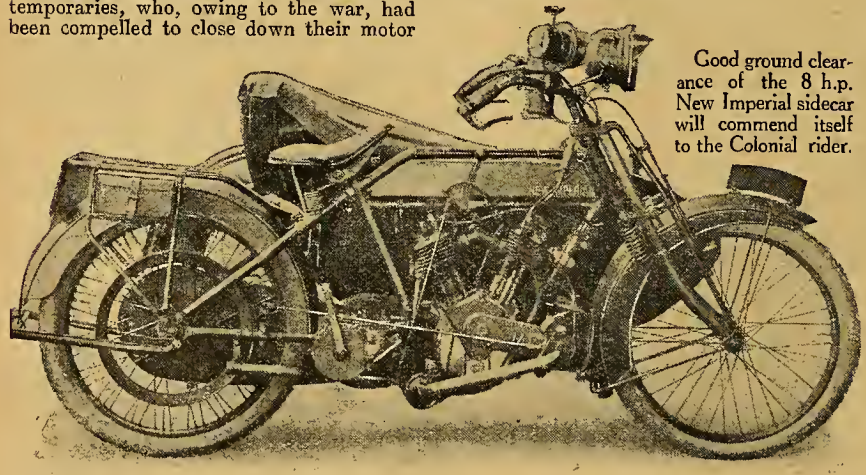
The 3½ h.p. two-speed P. and M. sidecar outfit.

One feature which is most commendable is the ratchet quadrant, by which one of the brakes may be secured. This is a great convenience, especially to the owner who lives in a hilly district, and not only relieves the hand of strain on a long descent, but facilitates an easy start, being made on a grade, since the driver does not have to attend to the brake when starting the engine.

The 1920 machine embodies a newly designed fork, and instead of the central enclosed springs in compression—the system on previous models—two separate coil springs in tension are provided. All moving parts are provided with grease cups of large size.

THE NEW IMPERIAL BIG TWIN.

Of the several J.A.P.-engined 8 h.p. twin machines on the market for 1919, the New Imperial figured prominently. It was originally designed as a military model for one of the Allied Governments, which used quite a large number of them for purposes of war. The requirements of this Government were practically identical with those of the average owner of a "big twin" sidecar, hence the New Imperial works at the signing of the Armistice were in a position to offer to the public a machine which had advanced in design more than several of their contemporaries, who, owing to the war, had been compelled to close down their motor cycle departments. It is not surprising, therefore, that few alterations have been found necessary for the 1920 model, and although improved or modified at minor points, the passenger machine which will appear at Olympia will not differ drastically from the 1919 machine. A black finish, however, perhaps gives the model a more handsome appearance, although the New Imperial has never been lacking in this connection. The standard sidecar is exceptionally large and comfortable, besides being well made.



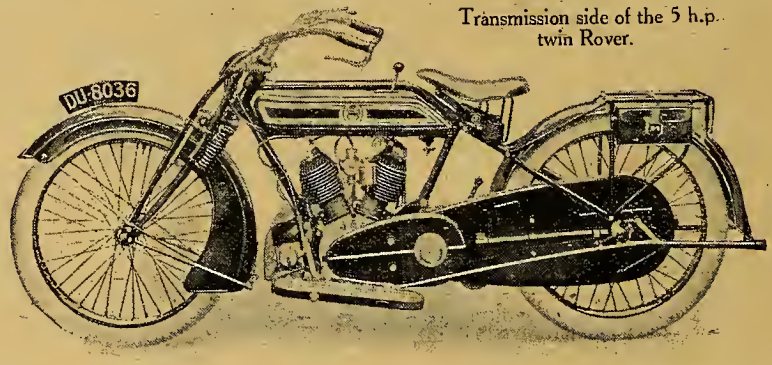
Good ground clearance of the 8 h.p. New Imperial sidecar will commend itself to the Colonial rider.

THE 5 H.P. ROVER.

Rover motor cycles have always been noted for their quiet running, and the 5 h.p. twin model introduced during the war for one of the Allied Governments is no exception in this respect. Having an engine of 654 c.c. capacity, it is one of the smallest twin-engined passenger machines on the market, but from our experience with it on the road it must be said that the impression gained, from speed and acceleration, is that the engine is much larger. The 1920 model differs very little from the 1919 machine, but, instead of a complete case enclosing the rear chain, a guard only is fitted.

The bore and stroke of the engine are 70 and 85 mm. respectively. The gear box is of the same type which has given such satisfaction on the 3½ h.p. model, which also will be retained as a passenger machine.

The finish, both mechanical and external, on the Rover products is extremely fine. Spring top links, for instance, have been fitted to the Druid pattern forks for many seasons, while the gear control is neatly concealed and works in a slot through the tank. This is one of the few machines employing a silent chain between engine and gear box.

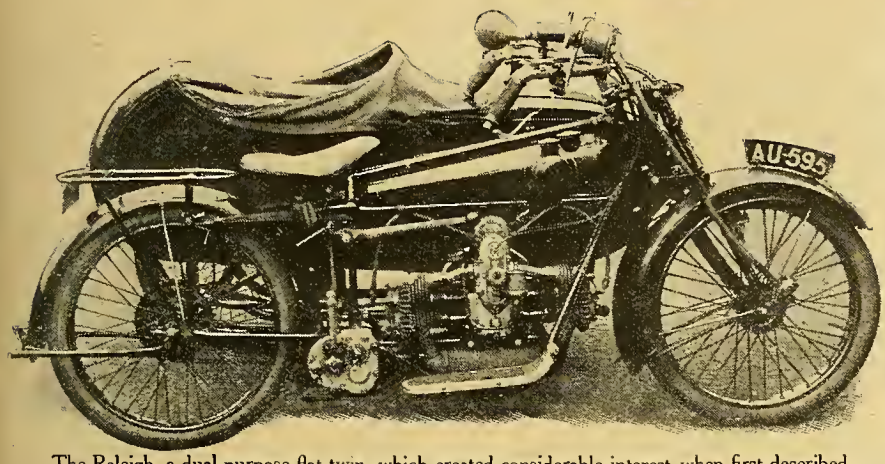


Transmission side of the 5 h.p. twin Rover.

THE RALEIGH DUAL-PURPOSE FLAT TWIN.

Although described in *The Motor Cycle* so far back as May 30th, last year, the Raleigh flat twin is a machine which will be offered to the motor cycle public for the first time at Olympia. The Raleigh Co. was among the leading motor cycle makers thirteen years ago, but for several years the firm has concentrated upon the production of high-class pedal cycles. The reputation created in this particular field makes the new motor cycle model of especial interest, and as the designer was for many years closely associated with a famous motor cycle, it is only reasonable to expect that the Raleigh flat twin will take its place in the front rank.

The engine is a beautiful piece of work, and has a bore and stroke of 77 and 70 mm. respectively, the capacity being 654 c.c., making it a machine equally suitable for solo or sidecar work. The frame is of the duplex type, and is of neat design, which makes possible a comparatively short wheelbase, the weight of the complete machine being only 240 lb. with a full tank and equipment. This is exceptionally light for a machine of its size, and which has a spring frame.



The Raleigh, a dual purpose flat twin, which created considerable interest when first described.

Transmission is by chains through a Sturmey-Archer gear box, placed compactly in the frame.

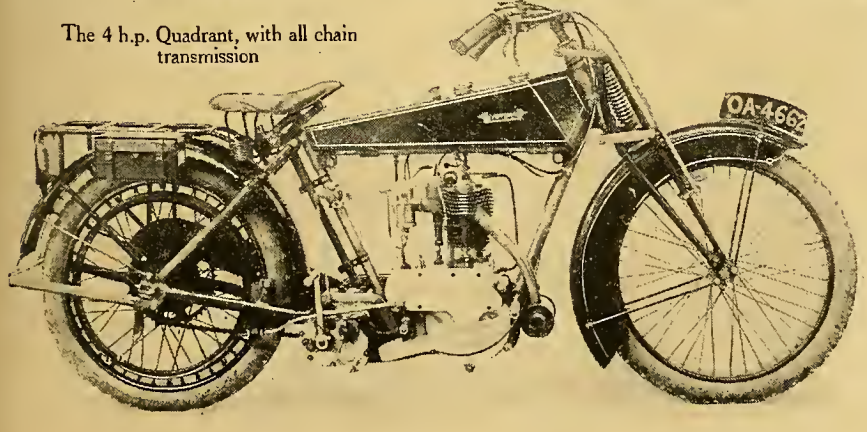
The illustration depicts the experimental model, but, we understand, the machine which will be exhibited at Olympia will differ only in minor points.

BIG SINGLES—THE QUADRANT PROGRAMME.

Two single-cylinder passenger machines will form the leading products of the Quadrant Company. One of these has an engine with a bore and stroke of 87 and 110 mm. respectively (654 c.c.), and the other 95 × 110 mm. (780 c.c.). Thus, the two Quadrants probably will be the largest singles offered at Olympia. Of particularly sturdy construction, both machines have diagonal top tubes, and are fitted with saddle tanks. The smaller model follows more or less conventional lines and has a Sturmey-Archer three-speed gear box and all-chain drive, but the larger machine has a three-speed gear incorporated in the crank case construction, in a most ingenious manner. These machines were described fully in *The Motor Cycle*, October 30th.

The Quadrant name has been associated with motor cycle developments from the earliest days of the movement, and it is therefore significant that, despite the present tendency in the direction of light high-speed power units, this firm is still faithful to the big single-cylinder.

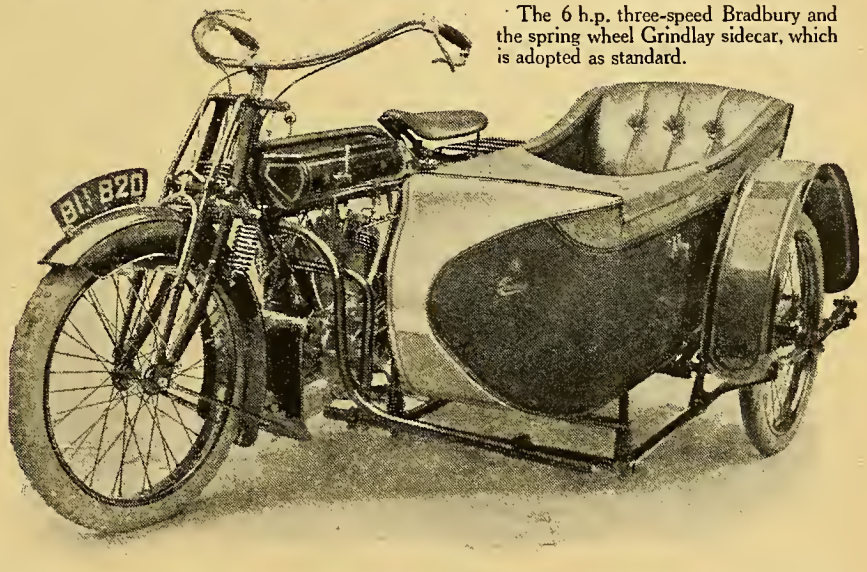
The 4 h.p. Quadrant, with all chain transmission



BRADBURY PASSENGER MODELS.

This Northern firm has long been noted for sturdily constructed machines, and has made history many times in the past with the 4 h.p. single-cylinder models. Although this type is still being manufactured, the 6 h.p. V twin is now being put forward for the prior claim as a passenger motor cycle. Since the general specification is the same for both types, most of the details below are applicable to both, although it must be remembered that the crank case of the single-cylinder model is built into the frame, while the twin engine is fitted with bolts and plates in the usual manner. The 6 h.p. engine has a bore and stroke of 74.5×86 mm. = 749.75 cc. and is fitted with detachable cylinder heads. A B. and B. carburetter and E.I.C. magneto are used, the latter being controlled by a lever on the side of the tank. Transmission is by partially enclosed $\frac{5}{8}$in. × $\frac{3}{8}$in. chains, and a Bradbury three-speed gear is fitted. This gear incorporates a cork insert with interconnected handle-bar and foot controls clutch, and a very efficient kick-starter. Druid forks are fitted, and the general finish is excellent, black and gold being used. Large tyres of light car section are fitted, and the rear wheel is quickly detachable, leaving the chain sprocket and internal expanding brake *in situ*. The Grindlay spring wheel sidecar has been adopted as standard, and this is fixed by four points of attachment, the duplex front down tubes of the motor cycle being built into a heavy lug adapted to receive the main front sidecar construction.

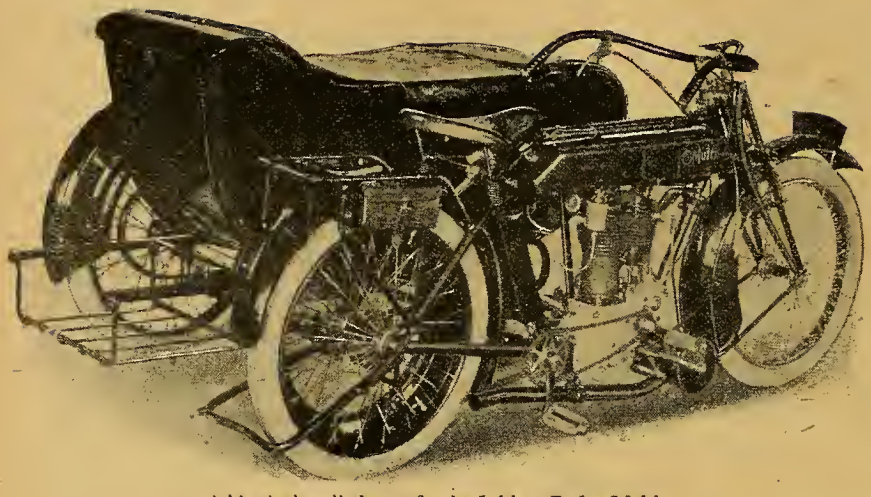
The 6 h.p. three-speed Bradbury and the spring wheel Grindlay sidecar, which is adopted as standard.



THE RUDGE SIDECAR RANGE.

Those who prefer high speeds with moderate engine revolutions and the smooth running of an infinitely variable belt transmission, will find that the Rudge machines conform to their requirements.

Two models are being specially recommended for sidecar work—the 5-6 h.p. single-cylinder (85×132 mm. = 750 c.c.) and the 7-9 h.p. twin (85×88 mm. = 998 c.c.). In each case the specification is similar, and both embody the well-known multi-gear with plate clutch on the engine-shaft. As in previous models, overhead inlet valves are employed, and these are carried in domes secured to the cylinder by three accessible stud nuts. Elsewhere in this issue, a detailed description of the 7-9 h.p. engine appears, to which the reader is referred.



A big single-cylinder outfit, the 5-6 h.p. Rudge-Multi.

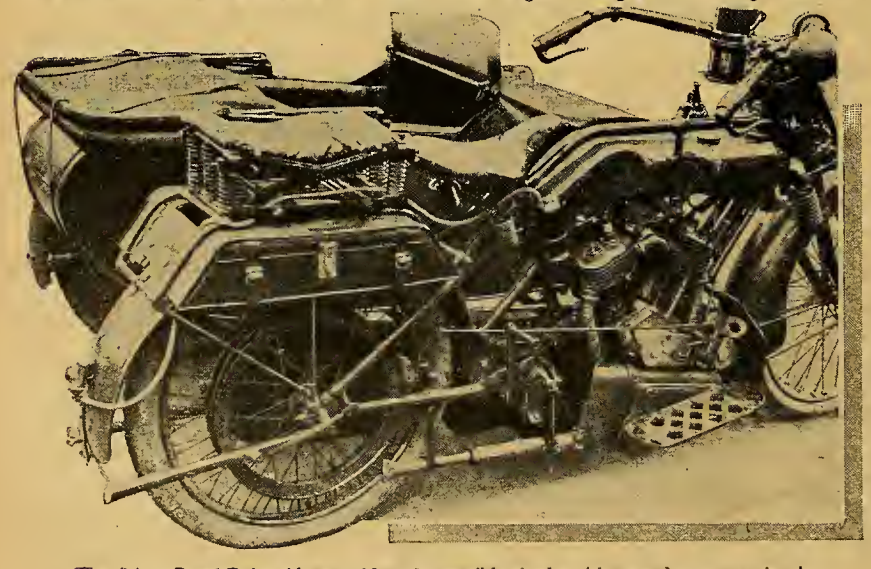
The Rudge sidecar is worthy of special note, since its bodywork is of exceptional finish, the appearance being enhanced by a polished aluminium front panel. Carried on springs is an angle-section steel subframe, and on this is mounted the body, luggage grid, and mudguard, so that everything is insulated from the effects of vibration.

Connections between the sidecar and cycle are four in number, and, as these are entirely composed of straight tubes, no danger of the sidecar coming out of alignment or leaning away from the vertical need be anticipated. Another excellent feature of the sidecar is its luggage-carrying accommodation, since, in addition to the capacious grid, a large locker is contained in the body at the rear.

THE ROYAL RUBY TWIN.

There are several noteworthy features on the twin Royal Ruby—a machine which has of late taken an important position among high-powered outfits. Engined with an 8 h.p. J.A.P. unit, the frame construction is unique, having triple tubes forming the member between engine and the steering head, while an additional tube forms a triangle within the larger triangle formed by the rear wheel frame. The carrier is exceptionally sensible in design, and accommodates two large valises protected on the sides and back by a metal case. A large pad brake working inside the V of a special rim, all-chain enclosed drive, and a large and comfortable sidecar form part of the equipment.

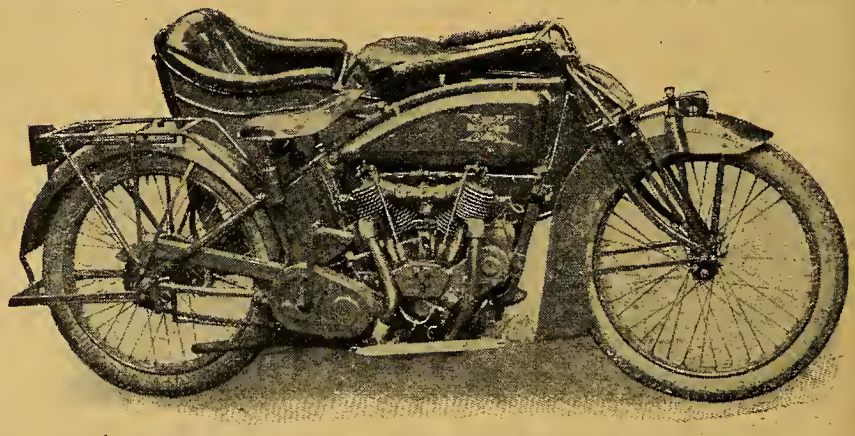
Amongst other things which should be noticed on the machine to be exhibited at Olympia is the improved type of spring frame. The designer responsible for the Royal Ruby has made a special study of springing, and his device, therefore, is eagerly anticipated.



The 8 h.p. Royal Ruby sidecar Note the sensible sized tool bags and unconventional design of carrier.

AMERICAN EXCELSIOR BIG TWIN.

Described in our issue for September 18th, the American Excelsior is a big twin of which more will be known in the future. The lastest model is a great improvement on the point of finish over the pre-war machines. The engine capacity is 1,000 c.c. and it has overhead inlet valves. The valve gear is extremely simple, there being only one large gear wheel with a cam on each side, one operating, through roller rockers, the inlet valves and the other the two exhaust valves. A Midco combined lighting and ignition set is standard equipment and consists of a generator, transformer, and contact-breaker, the whole being carried in the position usually occupied by the magneto. The all-chain drive is on the right side of the machine.



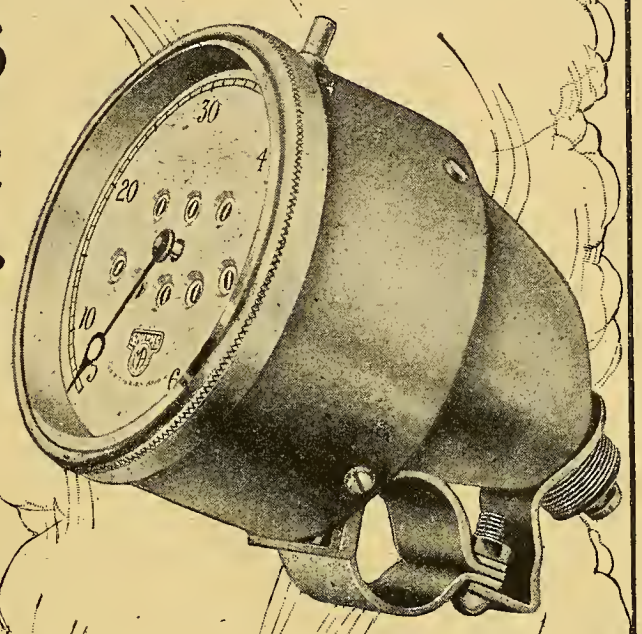
Valve side of the 7-9 h.p. American Excelsior. Sidecarists will note with interest that the transmission is on the right side.

A TWO-STROKE OUTFIT—THE $3\frac{3}{4}$ H.P. SCOTT.

By reason of its unconventional appearance, the Scott is perhaps not so universal in its appeal as it deserves to be. Those who ask for smooth torque, the maintenance of high average speed, simple control, and silent running will find their requirements met in this two-cylinder, water-cooled two-stroke mount. The frame is open and consists of straight tubes throughout, the oil being carried in the main frame tubes, while the petrol tank, which is covered with a leather-surfaced fabric, encircles the seat tube.

Lubrication is automatic, and a separate drip feed controls the supply to each crank chamber; a much deeper radiator is used than heretofore, and the engine keeps remarkably cool.

Smith's Motor Cycle Speedometer



the world's best speed-measuring instrument for motorcycle use will be on exhibition at

OLYMPIA
Motor Cycle Show,
Stand No. 200
(In the Gallery)

Amongst other Smith products on view will be: Motorcycle Watches, complete Electric and Acetylene Lighting Equipments, "Safety First" Warning Signals, K.L.G. Plugs, M.L. Magnetos, "Radamax" Plug Testers, etc., etc.

You must see this exhibit, and write for descriptive catalogue to:

Accurately Indicates Speed"

AFTER ELEVEN YEARS.

The G.N., evolved over eleven years ago to meet the needs of a simple and efficient two-seater, has, through strenuous application and in the light of practical experience, developed a high standard of performance, economy and comfort.

A WELL-EQUIPPED MODERN WORKS, capable of turning out 100 cars a week, has now been acquired, and the present output will be greatly increased in the next few months.

IN FRANCE, ALSO, the G.N. is starting on quantity production, and was a great attraction at the Paris Salon.

THUS, AFTER ELEVEN YEARS, the G.N. perfected, offering the luxurious comfort of the touring car at the cost and economy of the motor cycle and side car, has not only proved itself in constant service and open competition, but is in mass production in two countries to meet its ever-growing demand.

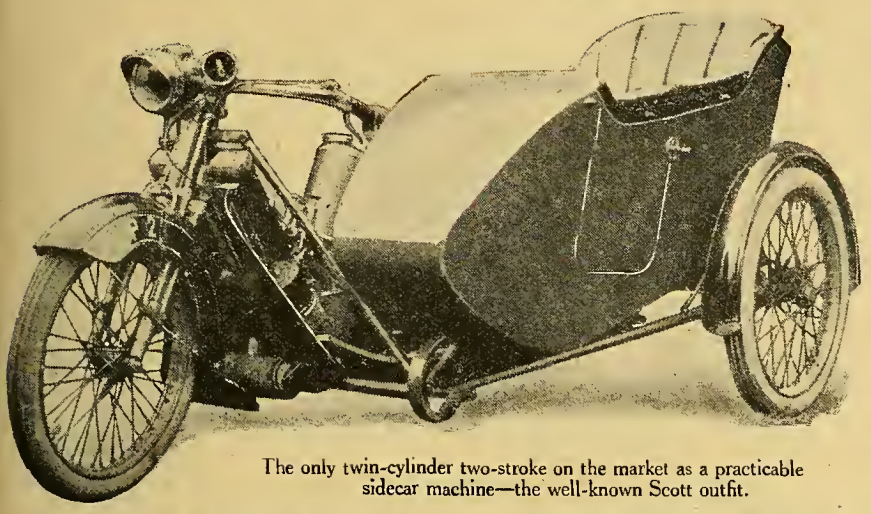
G.N., *Limited*, EAST HILL, WANDSWORTH.

AT OLYMPIA

STAND

6

In answering this advertisement it is desirable to mention "The Motor Cycle."



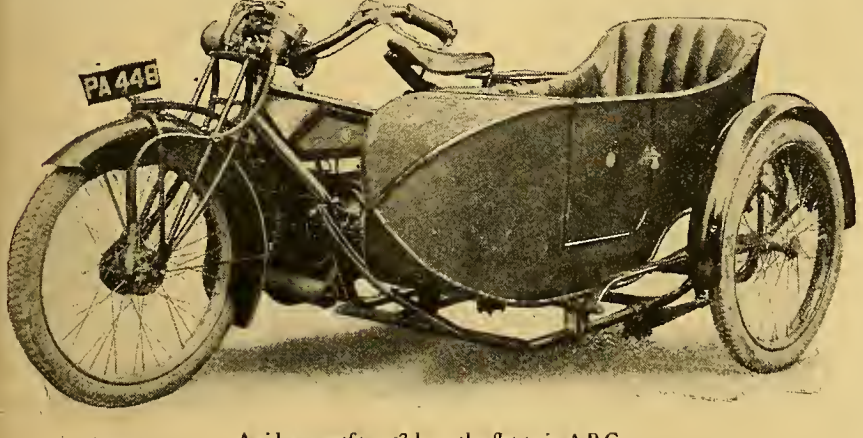
The only twin-cylinder two-stroke on the market as a practicable sidecar machine—the well-known Scott outfit.

Two speeds are fitted, both gears being direct; the transmission is through two chains to the countershaft sprockets and one to the rear wheel. Expanding clutches, operated by a pedal, connect either high or low gear sprockets to the countershaft, which carries the final driving sprocket.

A very handsome sidecar is supplied to fit directly on to the four sidecar lugs fitted in the frame, and the chassis follows the same principles of triangulation as the motor cycle. No curved tubes are employed, and the connections need no adjustments. The body is fitted with a receptacle in the front for spares, waterproofs, and other oddments, and a large locker behind the seat, to which access may be had without disturbing the passenger. Luxurious suspension by a system of levers and coil springs is incorporated, the front of the body also being mounted on a large central leaf spring.

A.B.C.

Although designed primarily as a solo machine, the A.B.C., in spite of the small size of its engine (68.5 × 54 mm., 398 c.c.), has proved itself well able to take a sidecar. This was made very evident on Peace Day, when it won the sidecar class on Stile Cop, beating large machines both on time and formula. Only a few of our readers have had an opportunity of sampling the A.B.C., but most of them know that its principal features are a flat twin engine set transversely in the frame and fitted with steel cylinders and aluminium pistons, also a very comfortable springing system. The engine has an enclosed flywheel, but not in its crank case, and the transmission consists of a bevel drive, a four-speed gear box, and a chain to the back axle. A special platform has been arranged to accommodate a Lucas dynamo, as fitted to the Magdyno recently described in our pages, and a speedometer drive is also contained in this most complete unit. Springing is by means of laminated springs, those in the rear being anchored at both ends, one leaf only running the full length of the spring, and forming the bottom leaf in front and the top one in the rear. The front spring is anchored over the wheel instead of in the usual position beneath the head, and the sidecar wheel is sprung to suit the bicycle. Lubrication is by a mechanical pump from an oil supply in the tank.

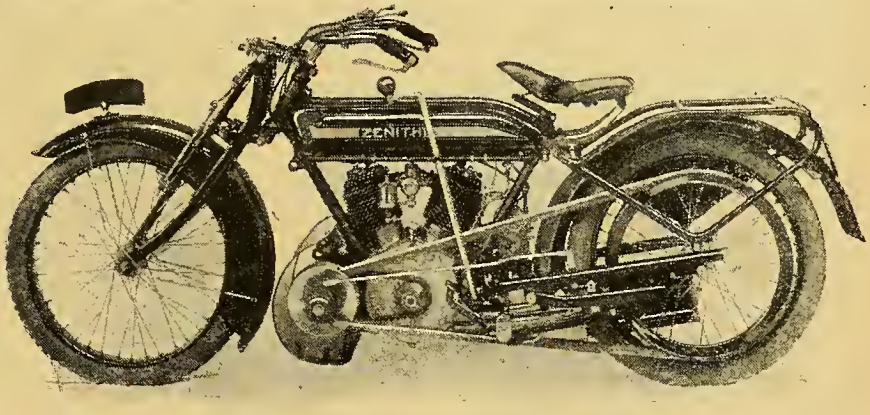


A sidecar outfit o. 3 h.p., the flat twin A.B.C.

THE ZENITH 8 H.P. TWIN.

The 8 h.p. Zenith has always had a special attraction for the sporting rider, probably because of its low and racy build. In spite of this, the machine is none the worse as a touring proposition; in fact, the Gradua gear provides a means of obtaining a correct gear ratio for all normal hills, and though it is not possible to obtain as low a bottom gear as is the case with a gear box, the direct chain and belt drive has the advantage of increased efficiency, in that there is no loss through oil churning and friction in the gear box.

Our readers will remember that modern Zeniths have a chain driven countershaft in front of the engine. With this countershaft a clutch is incorporated, and because of its position a very long final belt drive is obtained—a sound feature, which is worthy the attention of other makers.



Zenith motors will retain the essential features of the pre-war models

The latest improvement in Zenith passenger machines is the adoption of the Barnes spring saddle, a device patented by Mr. F. W. Barnes, of the Zenith Company. The springing of this saddle is so efficient that it is likely to take the place of a spring frame in certain 1920 mounts.

Both the Zenith-Gradua gear and the J.A.P. engines, with which this machine is fitted, are too well-known to need description; and Zeniths have proved their worth both on road and track too often to require our praise. A 5 h.p. model is also made and fitted with the J.A.P. engine and Gradua gear.

THE MOTOSACOCHE.

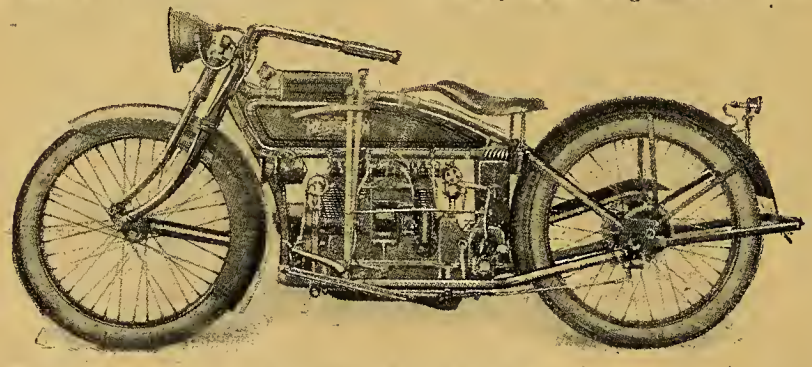
Since the day when it made its first appearance as a "motor in a toolbag," the Motosacoche has developed very greatly, and the 8 h.p. (82×95 mm. = 1,003 c.c.) is an eminently desirable sidecar machine The M.A.G. engine has overhead inlet valves, and the operating rods work in tubes through which oil can pass from

the crank case to lubricate the overhead rockers. These are, of course, enclosed. An adaptation of the Enfield expanding clutch gear has been devised, which gives three speeds instead of two (by means of three chains running between the engine and countershaft), and is very readily adjusted for the purpose of taking up wear, which takes place very slowly. Quickly detachable wheels are supplied, and both front and rear brakes work inside the V of the dummy belt rims. The saddle tube and footrests are supported on a large coil spring in tension—somewhat after the manner of the Bat. The engine is started by a handle through the countershaft.

THE FOUR-CYLINDER HENDERSON.

Those who like plenty of power combined with a sweet running engine are bound to be attracted by the big four-cylinder Henderson. As is the case with other American machines, the Henderson refuse to be limited by our arbitrary maximum of 1,000 c.c., and the latest models have a capacity of 1,168 c.c.

The four-cylinder engine has its inlet valves placed directly above the exhaust valves, and the three-speed gear box is formed in the flywheel cover plate. The arrangement, though somewhat unusual, is very neat. A multi-plate clutch is housed in the flywheel, and the power is transmitted through a pair of bevels to the gearshafts, which lie across the frame. The final drive is by chain.



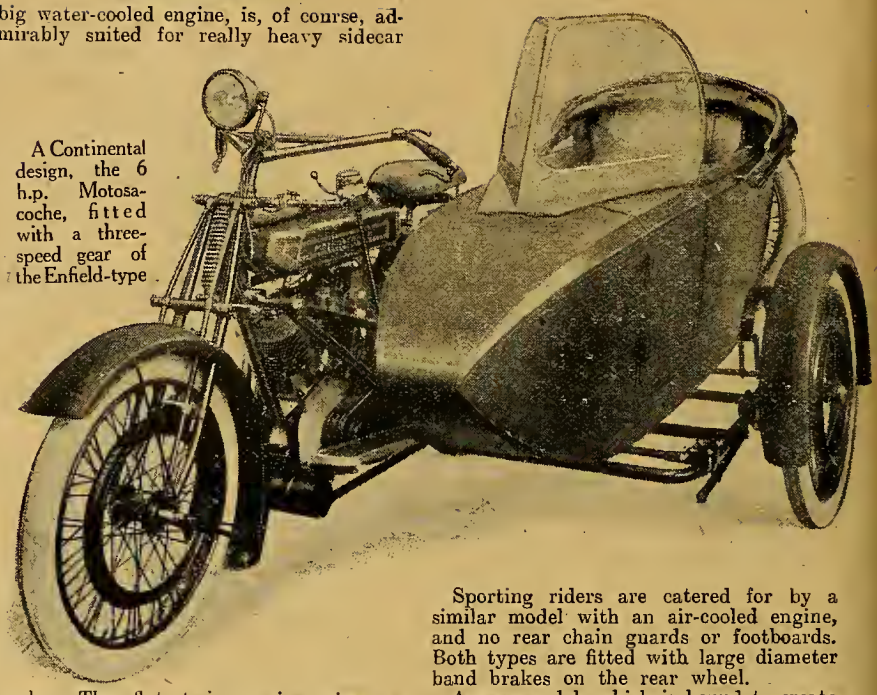
The American 10 h.p. four-cylinder Henderson.

A duplex frame carries the power unit, and the absence of saddle tube is counterbalanced by specially stout construction throughout.

As might be expected with a large luxurious mount of this description, an electrically equipped model is standardised. It is perhaps hardly necessary to state that the owner of such a sidecar outfit is not likely to be troubled with insufficient power unless the engine is seriously out of tune. Other features common to most American motor cycles are mechanical lubrication, 28in. × 3in. tyres, twist grip control, and folding footboards. A comfortable and well sprung saddle is employed in lieu of a spring frame.

WILLIAMSON.

One of the few water-cooled motor cycles on British roads is the 8 h.p. Williamson, which has a flat twin engine of 85 × 85 mm. bore and stroke. This big water-cooled engine, is, of course, admirably suited for really heavy sidecar work. The flat twin engine gives a regular impulse and excellent balance, so that there is no discomfort even on long stretches of low gear work. Chain drive is employed throughout, both primary and secondary chains being enclosed. A two-speed gear is mounted on the neat duplex frame, and, in addition to deeply valanced mudguards, very long footboards help to protect the rider.



A Continental design, the 6 h.p. Motosacoche, fitted with a three-speed gear of the Enfield-type.

Sporting riders are catered for by a similar model with an air-cooled engine, and no rear chain guards or footboards. Both types are fitted with large diameter band brakes on the rear wheel.

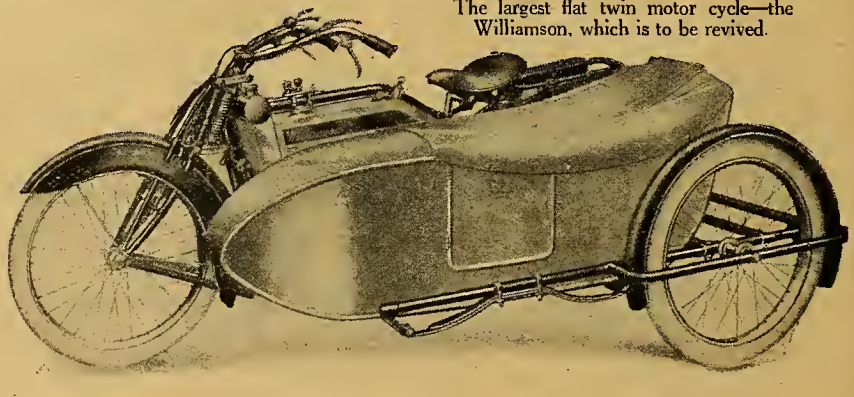
A new model, which is bound to create interest at Olympia, will be a 6 h.p. V twin machine. This model has a J.A.P. engine fitted in the unconventional Williamson duplex frame. Long spring footboards will be fitted.

The Williamson Motor Co. were the orginators of the motor cycle cab—a luxuriously appointed sidecar with a D-fronted landaulet body. The Victoria is a lighter form of sidecar in which the passenger can be totally enclosed, and two-seated sidecars with both side-by-side and tandem seating accommodation are listed by the firm.

Naturally a sidecar chassis to carry such bodies has to be stoutly constructed, and this point has received much attention, the side-members being trussed and staged, and no less than five cross-members being utilised. The bodies are carried on leaf springs throughout.

ENFIELD.

If any special proof had been needed (which was not the case) of the excellence of the Enfield 6 and 8 h.p. sidecar outfits, it would have been provided by the A.C.U. Trials, in which the Enfield team took first place among the passenger-



The largest flat twin motor cycle—the Williamson, which is to be revived.

M-L

LIGHTER SMALLER AND MORE ENERGETIC

THE M-L MAGNETOS—of which 50,000 have been supplied to H.M. Government — embody a number of special features, each of which makes a distinct advance on all previous practice, and goes to establish the efficiency and superiority of the M-L.

Among them may be mentioned laminated pole shoes, easily accessible terminals, very light weight, watertightness, new patent distributer, and high-tension brushes, which can be detached without disturbing the magnetos.

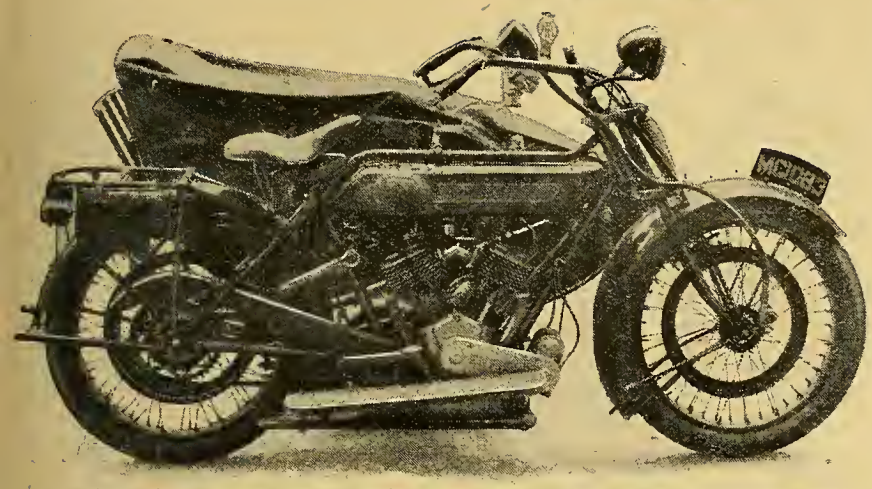
The FAMOUS K·L·G SPARKING PLUG

SOLE DISTRIBUTORS FOR THE ENTIRE WORLD

S. SMITH & SONS, (M.A.) LTD.,

179-185 Great Portland St. LONDON, W.1.

Manufactured by THE ROBINHOOD ENGINEERING WORKS LTD LONDON



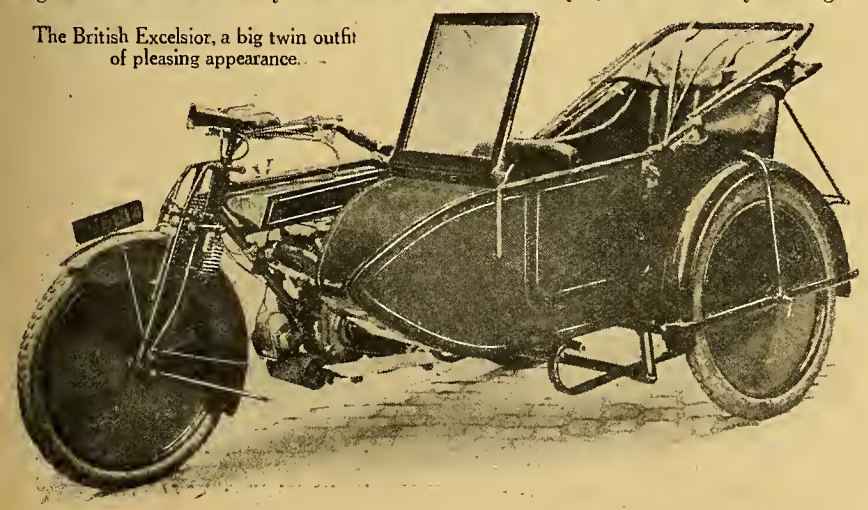
A popular outfit, the two-speed Enfield sidecar, which is supplied with either 6 or 8 h.p. engine.

carrying machines. The Enfield is sold always as a complete outfit, and not as a motor cycle to which a sidecar can be attached. J.A.P. twin engines are fitted generally to the 6 h.p. (76×85 mm.=770 c.c.), but sometimes to the 8 h.p. model (85.5×85 mm.=976 c.c.). The Enfield selective clutch gear is, of course, embodied, combined with a starting handle attached to the rear down tube. Lubrication is by Enots sight drip-feed circulated in the engine on the J.A.P. principle. A hand pump is also fitted with leads both to engine and gears. The front mudguard is domed and wide enough to extend beyond the forks—an Enfield feature which has been copied by others. Transmission is by chain throughout, and both speeds are direct. The sidecar is an excellent example of the coachbuilders' art, and is provided with a luggage grid.

THE BRITISH EXCELSIOR.

Manufactured with either a 6 h.p. or an 8 h.p. engine, the sidecar outfit which will be offered by the Excelsior Motor Co. (or Messrs. Bayliss, Thomas and Co., as they are better known) is quite an attractive proposition, designed and produced by practical riders. It is a large machine with 28 × 3in. detachable wheels fitted with discs, totally enclosed chains, internal expanding brakes, and a J.A.P. engine. The sidecar may be obtained with an additional seat for a child, from which one may gather that the body is exceptionally large. Attached to the sidecar body is a grid, so that any luggage carrier is insulated from road shocks, and provision is also made for carrying the spare wheel. The price quoted is £162 10s.; £8 extra is charged for spare wheel and tyre, and £25 for dynamo lighting and electric horn. The Excelsior Co. has recently moved from Coventry into large and convenient works at Tyseley, near Birmingham, where it is expected the firm will be able better to cope with the demand for their products.

The British Excelsior, a big twin outfit of pleasing appearance.

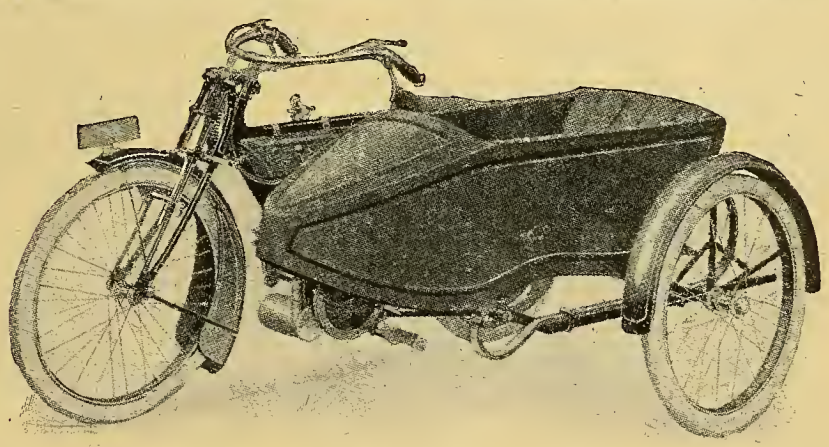


THE 1920 HUMBER.

The 1920 flat twin Humber, which is fully described in this issue, is likely to be a popular sidecar machine in 1920. During the past year, the 3½ h.p. model has met with very marked success, and the larger machine removes the impression we often experience in driving a 500 c.c. twin as a sidecar mount that a little more power is desirable, if not really necessary. The average 500 c.c. machine will easily propel a sidecar over any main road hill, but sometimes high average speeds are not possible, though, with an engine very little larger, the speed range is considerably increased.

THE IXION SIDECARETTE.

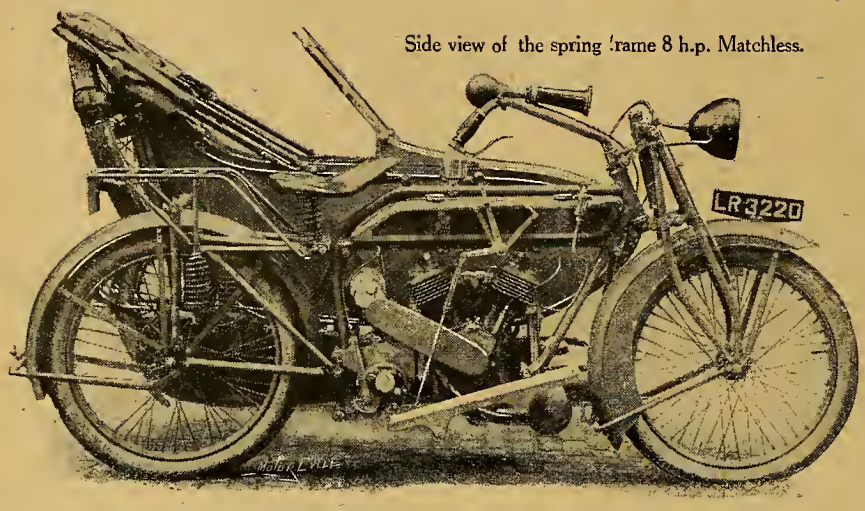
Although light sidecars are frequently attached to lightweight motor cycles not designed for passenger work, the number of makers actually producing lightweight sidecar outfits is not large. The Ixion sidecarette, however, is designed as a light runabout passenger machine, and as such it stands almost alone. The engine fitted in the 1920 model is a 350 c.c. Precision two-stroke, which has been proved very satisfactory for this service, with a Sturmey-Archer three-speed countershaft gear. The sidecar is particularly light and readily detachable. Machines of this type have been manufactured by the Ixion Co. for several years, and the inclusion of a sidecarette in the 1920 range is proof that there is a demand for a little passenger machine of this type.



A miniature sidecar outfit, the 350 c.c. two-stroke Ixion.

MATCHLESS.

There was a time when Messrs. Collier and Sons were known principally for the speed of their racing models, and for the doings of the Collier brothers in the Isle of Man and elsewhere; but, of recent years, they have turned their attention to the powerful sidecar machine, with what success many of our readers are aware. The outstanding novelty of Model H lies in the spring frame, which embodies a system of coil springs, so designed as to give an exceptionally large



Side view of the spring frame 8 h.p. Matchless.

movement to the rear wheel. The wheel fork is pivoted at its inner end, and a loop having lugs at its lower ends for carrying the springs passes over the wheel. This aids in giving lateral rigidity. The sidecar wheel is sprung in a somewhat similar manner, and the two are linked together. An 8 h.p. J.A.P. engine (85.5 × 85 mm., 976 c.c.) supplies the power, and enclosed all-chain transmission is used, passing through a three-speed gear box. A spare wheel is carried on the back of the sidecar. The method of mounting the saddle by pivoting the front on the top tube and supporting the rear on springs gives a low position.

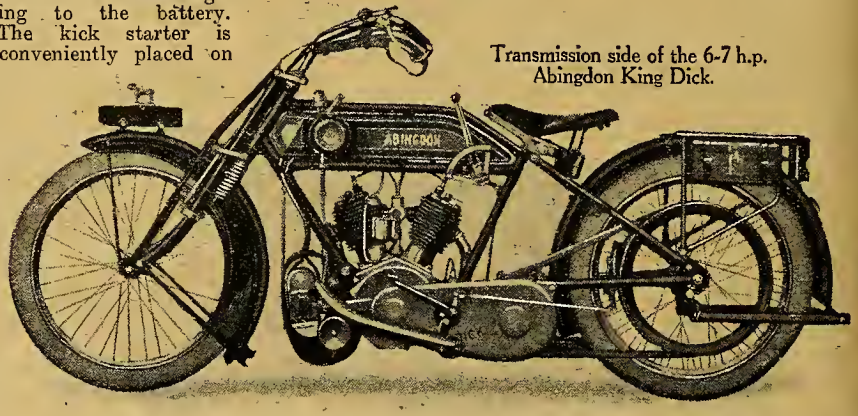
INDIAN POWERPLUS.

America has for many years been famous for big twins (largely due to the Indian) which, while often used for solo riding, are pre-eminently suitable for passenger work. The engine of the Powerplus Indian has a bore and stroke of 79.3 × 100.8 mm. (997.6 c.c.), and has been improved by the fitting of larger valves. The mainshaft and big end are equipped with roller bearings. The Indian spring frame, which has been in successful use for seven years, is retained, as is the twist grip control so popular on the other side of the Atlantic. In common with other American models the Indian has the advantage of large wheels and tyres. This model is electrically equipped, and is provided with an ammeter on the top tube (where the speedometer also is situated), which indicates the amount of current going to the battery. The kick starter is conveniently placed on the right side of the machine. For the coming year the sidecar has been redesigned; it is roomy and comfortable, and has, moreover, in the rear a large receptacle capable of carrying petrol and oil, and a considerable amount of luggage. All the sidecar connections are attached to the rigid members of the cycle frame, so that the springing is in no way rendered inoperative by the fitting of a passenger attachment.

Before the war, the 5 h.p. Indian was quite a favourite machine among British sidecar drivers, and no doubt the new Scout model, although designed for solo use, will find favour among those who prefer an engine of comparatively low capacity for sidecar work. The new model has a twin engine of 574 c.c., and the primary drive is by a train of gears to a three-speed gear box, the final drive being by chain. Unlike the majority of American machines, 26in. wheels are fitted, and the complete machine weighs 260 lb.

ABINGDON KING DICK.

Despite the somewhat restricted output of the Abingdon King Dick, owing to the demand upon the works of Messrs. Abingdon-Ecco, Ltd., for their other specialities, this machine has a standing reputation as a reliable and efficient mount, suitable for sidecar work. The engine fitted is of 6-7 h.p., the bore and stroke of 73 and 95 mm. respectively. A substantial three-speed gear box is fitted, and the frame used is of graceful design. The same quality which has characterised King Dick spanners for so many years is evident throughout the construction of this machine.

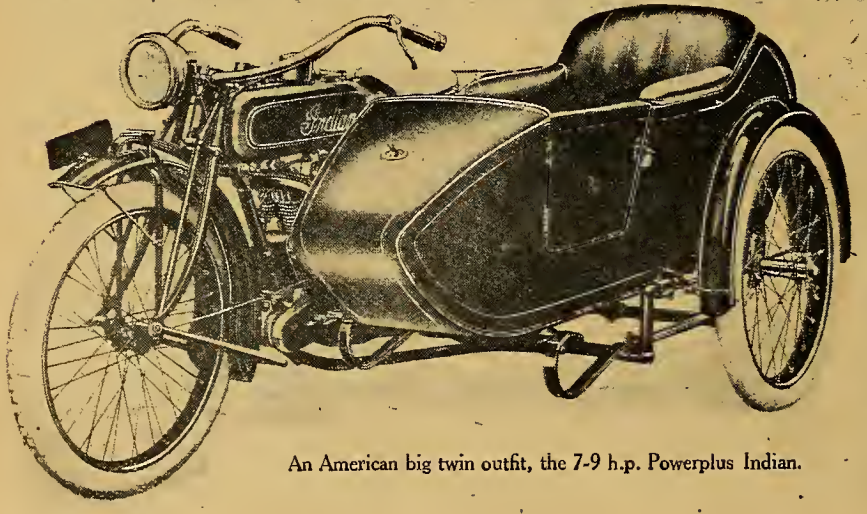


Transmission side of the 6-7 h.p. Abingdon King Dick.

Ease of operation has been constantly kept in view in the design of this machine. A comfortable riding position is assured by keeping the saddle well within the wheelbase. Beside the tank is a long gear control lever, which makes for easy changing, while enormous leverage is provided by the conveniently placed pedal of the rear brake. An all-chain model also will be marketed.

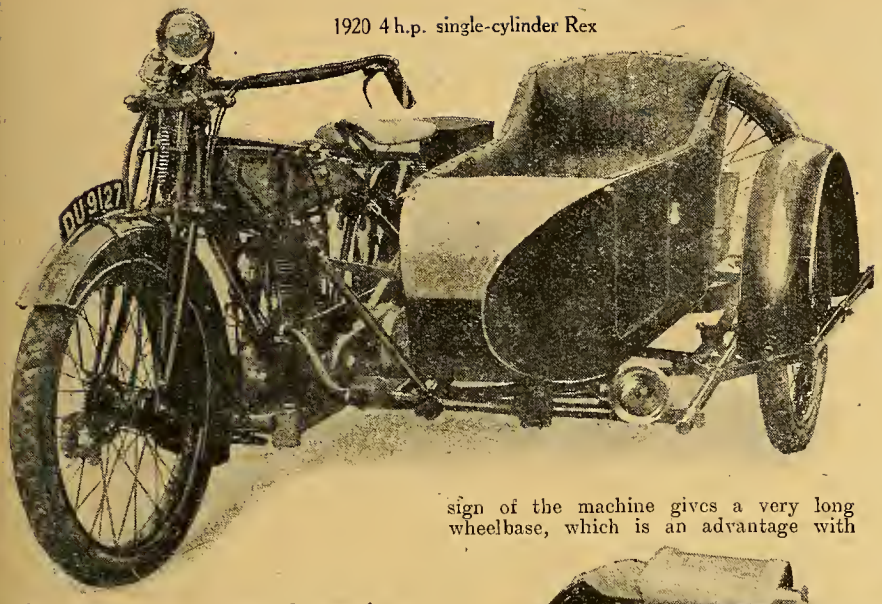
LEA-FRANCIS.

The Lea-Francis is not fitted with a large engine, and yet it is frequently used as a sidecar machine with much satisfaction; moreover, it is one of those machines which took a high place from the start. The engine is a J.A.P. 3½ h.p. twin (70×64.5 mm.=496 c.c.) The transmission is by enclosed chains, through a two-speed gear box, the chain guards being well carried out, and the machine is remarkable for its quiet running among



An American big twin outfit, the 7-9 h.p. Powerplus Indian.

1920 4 h.p. single-cylinder Rex

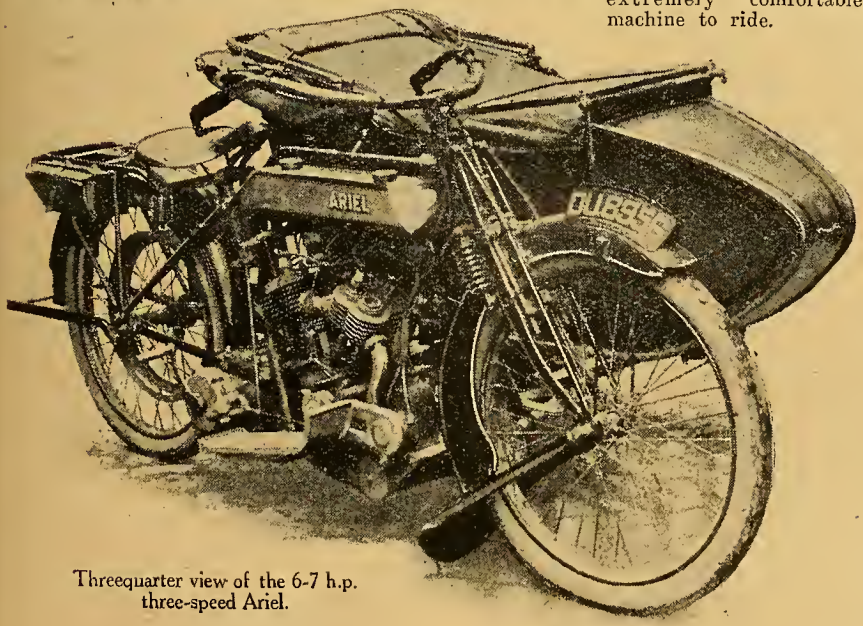


sign of the machine gives a very long wheelbase, which is an advantage with a sidecar machine, and, with the cantilever saddle suspension, the Rex is an extremely comfortable machine to ride.

other good points. The brakes work on the inside of the V on dummy brake rims. Messrs. Lea-Francis were, we believe, the first to use this type of brake on a front wheel. Another excellent feature is the quickly detachable wheel; the rear wheel can be removed for tyre repairs in a few seconds, leaving the transmission and brake work untouched. The hub design, both in front and rear, has much to recommend it, and the general finish of these machines is proverbial.

THE REX SIDECAR SINGLE.

One of the new single-cylinder sidecar machines produced since the Armistice is the Model 77 Rex, which has a 550 c.c. mechanically lubricated 84 × 98 mm. engine. Having 28 × 2½in. tyres and a large ground clearance, this model once more illustrates that all designers, in producing new models, have the requirements of the overseas buyer in mind. The design of the machine gives a very long wheelbase, which is an advantage with a sidecar machine, and, with the cantilever saddle suspension, the Rex is an extremely comfortable machine to ride.



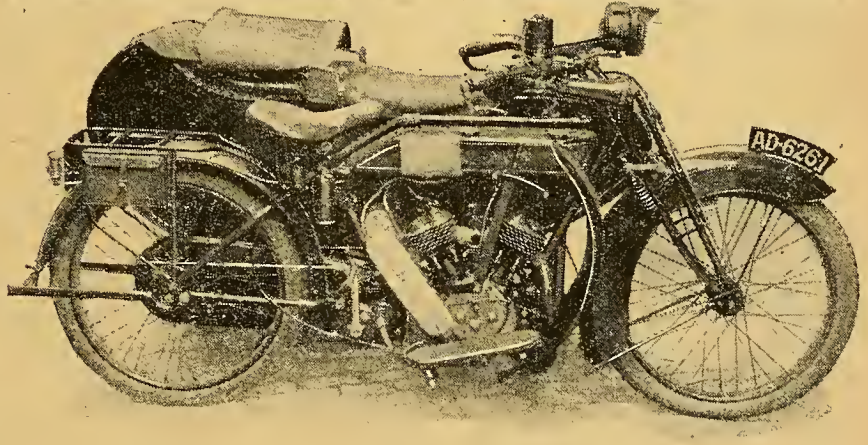
Threequarter view of the 6-7 h.p. three-speed Ariel.

Interchangeable wheels are fitted, and the equipment includes a spare wheel carried at the rear of the sidecar. There are several features which reveal a close attention to detail; for example, the brake pedal bearing is fitted with a large lubricator, as is the bearing supporting the belt wheel. The rear brake has a parallel motion, and the handle-bars are adjustable.

The engine is replete with novel points, as, indeed, anything may be expected to be which emanates from a firm who performed so much experimental work in the early days; in consequence those who favour such things as mechanical oiling and aluminium pistons will here find the incorporation of the latest practice.

THE JAMES PROGRAMME.

In the passenger machine class there will be two James models for 1920—a 5-6 h.p. twin and a 4¼ h.p. single. Both these machines are modified 1919 models, improved in detail and fitted with larger tyres. The bore and stroke of the twin

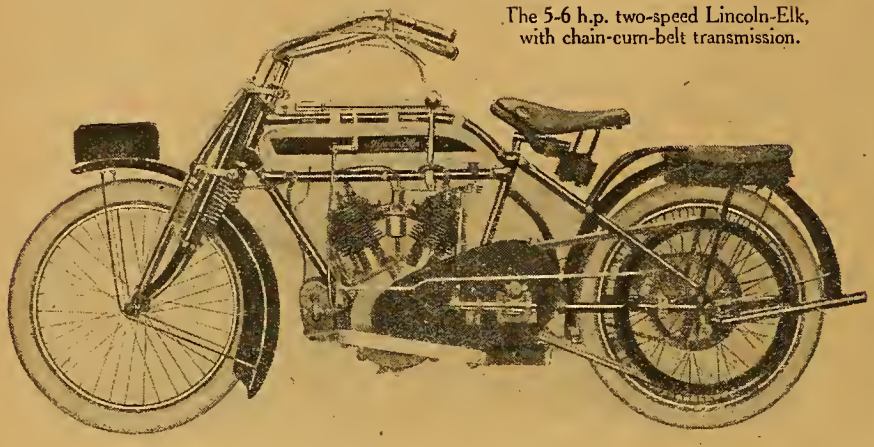


The 5-6 h.p. James sidecar outfit.

are 70 × 86 mm.—the capacity being 662 c.c.—which, in conjunction with the James three-speed gear box and all-chain transmission, makes a serviceable and economical sidecar machine considerably faster than may be supposed by its comparatively small engine capacity. The 4¼ h.p. model is a good representative of the big single class, which is so popular on account of its power and ability to maintain good average speeds with a sidecar load, and, at the same time, it is reasonably cheap to buy and maintain. This model has been a consistently good performer in the passenger machine classes in the 1919 trials.

THE ARIEL 6-7.

Engined with a long-stroke twin of 795 c.c. (73 × 95 mm.), the Ariel 6-7 is one which has become very popular as a passenger machine, on account of the remarkable staying powers of the engine. Various modifications in details will be made in the 1920 design, including all-chain drive with shock-absorber in the rear wheel. We have ourselves used one of these machines during the present year, and can testify as to its power, all-round reliability, and the exceptional comfort of the roomy sidecar. In addition, the well-known single-cylinder machine will also be marketed with a slightly larger engine.



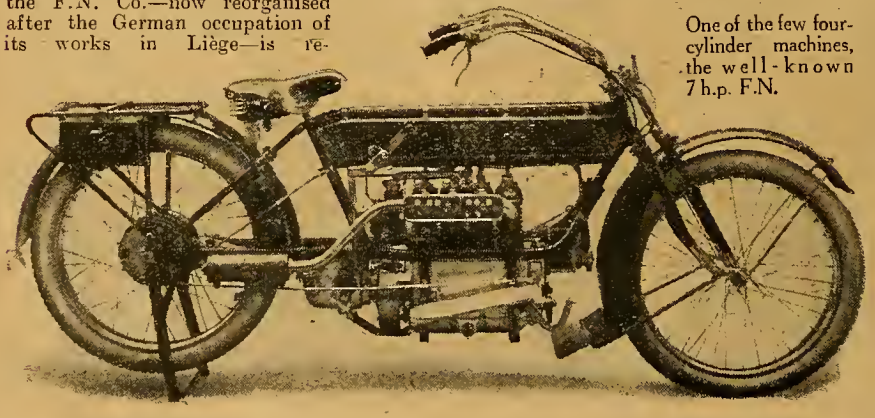
The 5-6 h.p. two-speed Lincoln-Elk, with chain-cum-belt transmission.

LINCOLN-ELK MOTOR CYCLES.

It is not usual for the motor cycle manufacturer to carry out all the various processes in the completion of his machines under his own control, but this is done by the makers of the Lincoln-Elk motor cycles. With the exception of such proprietary fittings as magnetos, carburetters, and saddles, everything, including the engine, is made in the one factory. Previous models having proved satisfactory, there is very little change to be made, a 5-6 h.p. V twin being specially made for sidecar work; 4½ h.p. single-cylinder models are also made. The power units are of the plain bearing type and drive through a unique form of two-speed gear, which consists of a countershaft connected to the engine by chain. On this shaft are two expanding rings controlled by a lever beside the tank, and these clutch either a large pulley or sprocket, which transmit the power to the rear wheel by belt on high gear and chain on low. The rear belt drum and chain sprocket are on either side of the back wheel. A kick-starter is fitted on the countershaft.

THE FOUR-CYLINDER F.N.

The influence of the F.N. four-cylinder machine upon ultimate design will only be fully appreciated by those who know the number of firms experimenting with four-cylinder motor cycles at the present time. There have been many four-cylinder machines, but of the many pioneer designs, only the F.N. has survived. It is a matter of great interest to learn that the F.N. Co.—now reorganised after the German occupation of its works in Liège—is re-introducing the 7 h.p. model, which promised to be such a popular machine when war broke out. Having cylinders of 52×88 mm., the capacity of the engine is 748 c.c.; it has a three-throw crankshaft and mechanical lubrication. Of T head design, the valves are arranged on each side of the cylinders and actuated by two camshafts driven by gears at the fore end of the crank case. The transmission is by shaft through a three-speed gear box placed immediately behind the engine flywheel, in which is incorporated a multi-disc clutch. The rear wheel is easily detachable.



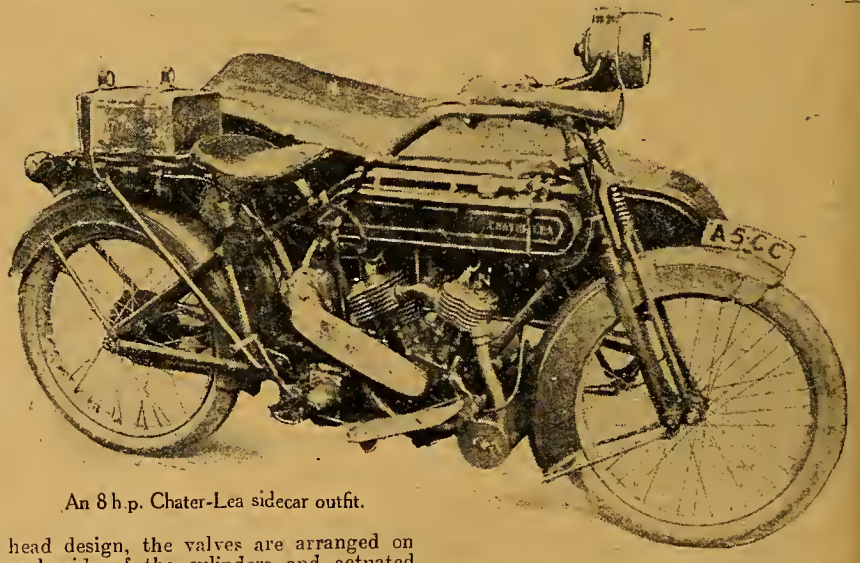
One of the few four-cylinder machines, the well-known 7 h.p. F.N.

COVENTRY VICTOR.

A flat twin engine unit of 5-7 h.p., which may be introduced by its makers in a complete machine, is the Coventry Victor. The bore and stroke are 75 and 78 mm. respectively, the capacity being 688 c.c. The experimental machine has every promise of success, and its appearance in the market largely depends upon the ability of the Coventry Victor works to produce it in addition to the engine unit, which is sold to assembling firms.

CHATER-LEA.

Amongst sidecarists the Chater-Lea (No. 7) has always possessed a well-deserved reputation for soundness and reliability. An 8-h.p. engine, of which the bore and stroke are both 85 mm. (964 c.c.), is fitted; from this the power is taken by a chain to the three-speed gear box (the firm has always been noted for the large size and consequent efficiency of its clutch), and a second chain to the rear wheel completes the transmission. Chater-Lea spring forks are standard, and strongly stayed 5in. mudguards, with side wings, are fitted. The Chater-Lea was one of the first machines to be fitted with an internal expanding brake, and this feature is retained in the latest Model No. 7. Journal ball bearings are used in the hubs, and the wheels are quickly detachable, leaving the transmission undisturbed.

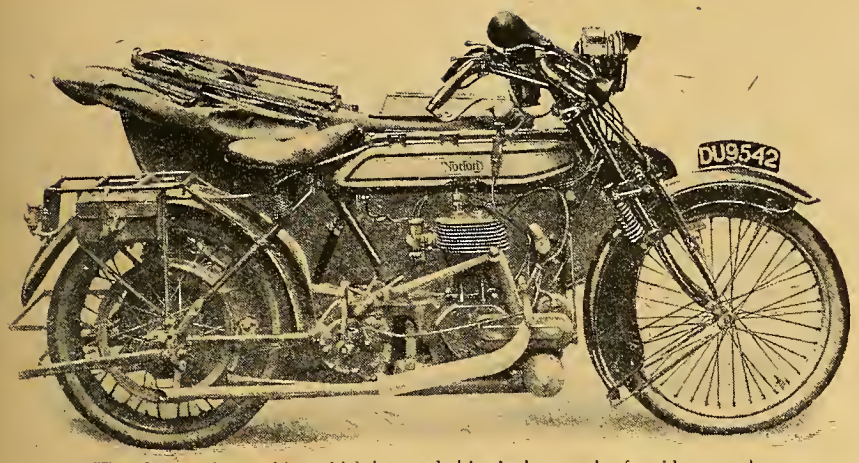


An 8 h.p. Chater-Lea sidecar outfit.

The Chater-Lea No. 7 is known among sidecar owners as a "hefty twin," which has been very successful in competitions, and that it is included in the 1920 range of models will give satisfaction to many past and present owners of the model.

"BIG FOUR" UTILITY NORTON.

Whilst not primarily designed for speed, like its 500 c.c. sisters, the "Big Four" Norton is one of the fastest sidecar machines on the road. The capacity of the engine is 633 c.c., the bore and stroke being 82 and 120 mm. respectively. 650 × 65 · tyres, Sturmey-Archer gear, hand-controlled clutch, enclosed all-chain drive, and a tank holding two gallons of petrol, form part of the equipment.



The Norton, the machine which has made big singles popular for sidecar work.

The standard Norton sidecar is of pleasing design, embodying a large rear locker which, to order, is utilised to accommodate a child's dickey seat.

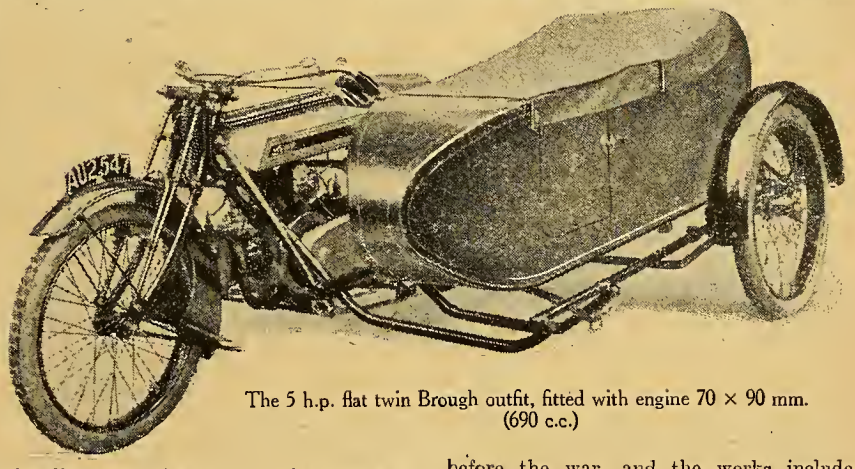
We have had one of these machines in constant use during the whole of this year, and on long journeys we have been surprised at the high average speeds possible with a heavy sidecar. Its high ground clearance and sturdy construction make it particularly suitable for use in the roughest country, and its economy in running will appeal to all.

THE CAMPION.

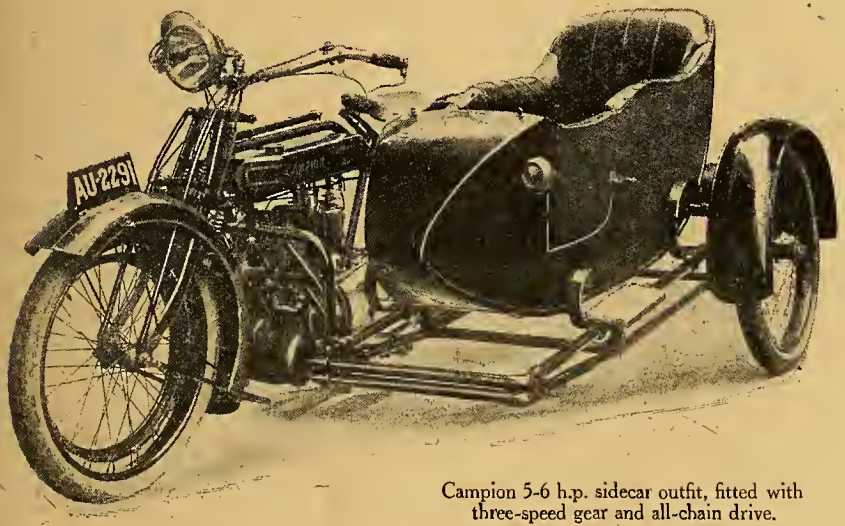
The Campion is one of those machines which would be better known if the output of its manufacturers were larger. Wherever it is known, however, it is appreciated because of its all-round commonsense design, which reveals that those responsible are keen road men. Engined with a twin J.A.P. unit, and built up of other standard components, the main distinctive features of the machine are its wide mudguards, large capacity tank, and comfortable riding position. The sidecar embodies what is practically a rectangular duplex frame, and is of particularly robust construction, the body is large, and, for the convenience of the passenger, a step is fitted.

THE BROUGH 690 C.C. FLAT TWIN.

In the recent Liverpool M.C. trial, the judges made a special point of engine cleanliness at the end of the gruelling day's run, and special mention was made by them regarding the qualities of the new Brough engines in this direction. The latest 5 h.p. model has a bore and stroke of 70 and 90 mm. respectively—one of the only long-stroke flat twins on the market. It has been designed by an engineer, who is also one of the best known riders in this country, Mr. Geo. Brough, and much is expected of it on this account. Undoubtedly it is a very fine piece of work, and one which will be much sought during 1920. The crank case is cast in one piece, and has a cover, over the timing gear, which embodies the main parts of the induction pipes. A solid crankshaft is used which runs on long plain bearings. The induction pipe is heated, and altogether the Brough should give a good account of itself in next year's motor cycle market. The gear box fitted is the Sturmey-Archer, and all-chain transmission forms part of the specification. Manufactured by the Brough firm, the sidecar is particularly attractive on account of its size and the quality of its upholstery and general finish. A capacious locker at the rear accommodates two suit cases, or petrol tins. Leaf springs are used for the suspension and the design embodies a spring wheel. Messrs. Brough and Co. are now in a much better position to produce motor cycles in quantities than was the case before the war, and the works include a foundry and well-equipped machine shops, so that almost every component part of the Brough machine is produced under one roof. The 5 h.p. Brough is also obtainable as a solo machine with higher gear ratios.



The 5 h.p. flat twin Brough outfit, fitted with engine 70 × 90 mm. (690 c.c.)

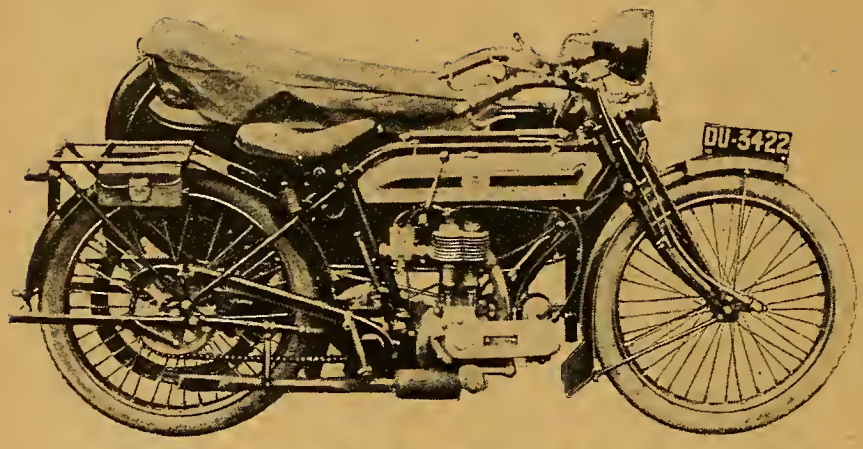


Campion 5-6 h.p. sidecar outfit, fitted with three-speed gear and all-chain drive.

THE MILITOR.

This American machine at present is not marketed in this country, but, owing to the interest created by its description given in *The Motor Cycle* on October 9th, there is every possibility that a number will be imported at a very early date, as its manufacturers make a speciality of export trade.

It will be recalled that the Militor is a four-cylinder motor cycle, built on the lines of a car, having a press steel frame and shaft drive. The springing, too, is on car lines, and another point where car practice is followed is the artillery wheels. The engine has cylinders 63 × 89 mm., and embodies overhead valves. A three-speed and reverse gear box is built integral with the crank case, the gear change being by a swivelling lever, as on many American cars. In America, the price of the machine with sidecar, which is also fitted with an artillery wheel, is £120.



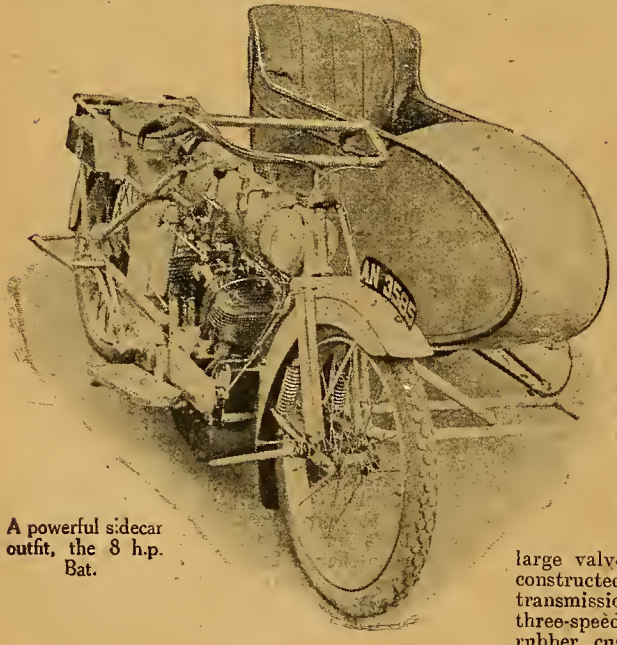
The Triumph 1920 chain drive machine used in the Six Days Trials.

THE TRIUMPH "FOUR."

The performance of the 4 h.p. chain drive Triumph with sidecar in the A.C.U. Six Days Trial was one of the outstanding successes of the year, and from our own experience with this model, we anticipate that it will be one of the most popular machines on the 1920 market. Elsewhere in this issue will be found a full and illustrated description of the new model.

THE BAT.

In the early days of motor cycling the Bat earned a high reputation which has been retained up to the present time. Sturdy construction and J.A.P. engines have always been features of these machines. Either the 6 h.p. (770 c.c.) or 8 h.p. (976 c.c.) engine can be fitted. The gear box rests upon a platform below the chain stays, which is supported at the rear of the crank case, and by the lower members of the frame. This method of attachment renders chain adjustment very easy. The kick starter has a partially enclosed pinion and ample leverage. The change speed lever is conveniently placed on the right-hand side of the tank, which, like all Bat tanks of recent years, is cylindrical with a tapered rear. The Bat method of springing which insulates the rider has been retained. The saddle and footboards are connected and supported by a strong spring and suitable links. This gives very comfortable riding and no lack of lateral rigidity, and has, moreover, stood the test of time.



A powerful sidecar outfit, the 8 h.p. Bat.

READING STANDARD.

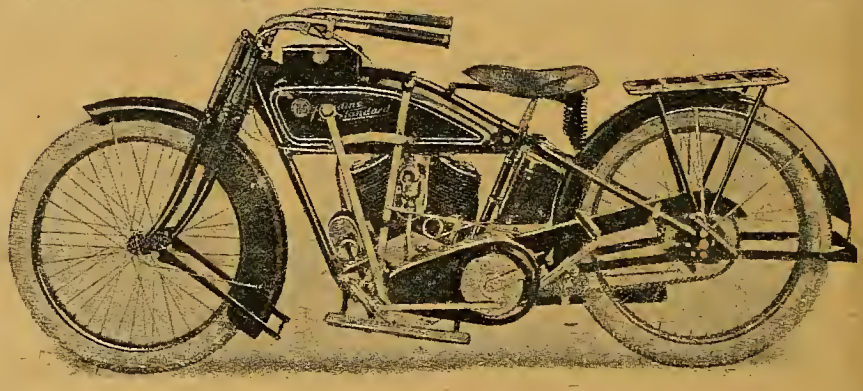
The Reading Standard has not hitherto been so common in this country as several other American makes, but it is likely to be seen much more frequently in the near future. The engine is one of the largest found on a motor cycle, the bore and stroke being 85.7 and 101.6 mm. respectively; this gives a capacity of 1,170 c.c., and the motor has shown 16 h.p. on the brake. The engine has large valve ports and a specially constructed exhaust valve. The transmission is by chains *via* a three-speed gear box, and a rubber cushion drive such as is used on the Enfield. Only one model is marketed, but this can be purchased with or without electrical equipment. The forks differ from those used on many American machines, and resemble the Chater-Lea in principle.

THE WILKIN "4."

Wilkin Motors of Sheffield is another new firm which will have a sidecar machine to offer in 1920. It will be engined with a 4 h.p. Blackburne unit, and the specification will include Sturmey-Archer gear, all-chain transmission, patent cush drive, and a two-gallon tank. The sidecar lugs will be cast integral with the frame.

A SIDECAR COULSON B.

One of this year's newcomers to the motor cycle manufacturing world is the F. Aslett Coulson Engineering Co., whose Coulson B lightweight has quite caught the public fancy. A sidecar model by this firm will be introduced early next year, in which the power unit will be the well-known Blackburne 4 h.p. engine.



An American big twin of 10 h.p.—the Reading Standard.

The experimental machine has several features of interest, not the least among them being the spring frame, which is similar to that used for the lightweights. The system embodies quarter-elliptic leaf springs supported on the side of the rear stays, the wheels being carried on short levers pivoting at the ends of the stays.

OTHER PASSENGER MACHINES.

There are sidecar machines, other than those reviewed in the preceding pages, of which particulars are not yet available. Most of these, however, will not appear on the market until early next year. Among these are several which will be produced by large firms at present unknown in the motor cycle field, but who, in changing over from munition work, have decided to devote extensive manufacturing facilities to the production of motor cycles.

One of these will probably take the form of a single-cylinder machine on more or less standard lines, designed to be produced in large quantities at a comparatively low price. Another will be an 8 h.p. twin with several distinctive features. A third will be an exceptionally large and interesting twin with outside flywheel and two overhead exhaust valves per cylinder.

There are also several four-cylinder machines which have been held up only on account of manufacturing difficulties occasioned by the several strikes.

HUTCHINSON

It is Odds on Olympia

being the best Show yet. And it is certainly odds on Hutchinsons being the **best Tyre** in the **Show.**

We look forward eagerly to meeting our multitude of old friends and to making new friends.

Welcome to Stand 68.

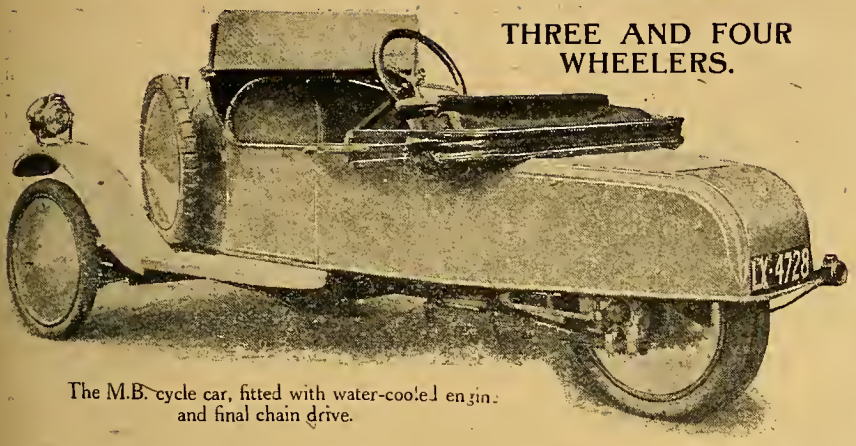
THREE AND FOUR WHEELERS.



The M.B. cycle car, fitted with water-cooled engine and final chain drive.

THE MERRALL-BROWN THREE-WHEELER.

Made by the Premier Motor Co. of Bolton, the Merrall-Brown runabout is a most distinctive machine, embodying many refinements in finish and equipment. The engine fitted is a water-cooled 10 h.p. four-cylinder, driving a two-speed and reverse gear box by shaft, the final transmission being by a single chain. The rear wheel is of the twin type, sprung by underslung quarter-elliptic springs, while semi-elliptic springs are used at the front axle. Chain tension is adjusted by radius rods controlling the movement of the back wheel. Wheels of the standard Dunlop detachable variety are fitted with discs. On each side of the back wheel are hand and foot brake drums, but the detachability of the wheel in no way interferes with the adjustment of these. Quite a pleasing design of body has been adopted, a streamline effect being obtained with approximately upright sides. In addition to the bonnet, the wings and wheel discs are of polished aluminium. A door is fitted in each side.

THE PREMIER RUNABOUT.

This three-wheeler, introduced by the Coventry Premier Co., who, before the war, made Premier motor cycles, was fully described in *The Motor Cycle* of October 30th. Its features include a three-speed and reverse gear box; shaft and chain drive, the latter by a duplex chain enclosed in a quickly detachable case; quickly detachable rear wheel, with spare wheel carried on the tail of the body; quarter-elliptic springing front and rear, the latter being in an inclined position; rack and pinion steering; foot acceleration; and a mechanically lubricated water-cooled V twin engine, with a bore and stroke of 80 × 105 mm. respectively (1,055 c.c. capacity). Fitted with hood, screen, and lamps, the provisional price of the Super Runabout, as it is called, is £210, at which price it is a most attractive proposition.

MORGAN.

Up to the present date, no three-track machine has earned such popularity as the Morgan, and it is not without good reason that one sees so many of these handy little runabouts on the road, for they have thoroughly proved their reliability. Only one chassis is made, and this is so straightforward that it would be difficult to suggest any part which could reasonably be lightened or rendered more perfectly simple. The engine, which may be either a water or air-cooled J.A.P. or M.A.C. or air-cooled Precision, is carried at the front of the chassis, and drives through a clutch to a propeller-shaft enclosed in one of the three main frame tubes. To the rear of this tube is attached a box containing a pair of bevels. The cross-shaft carries a sprocket on either side, each of which is connected by chains to the rear wheel. By simply "dogging up" one or other of these sprockets, two different gear ratios are obtained.

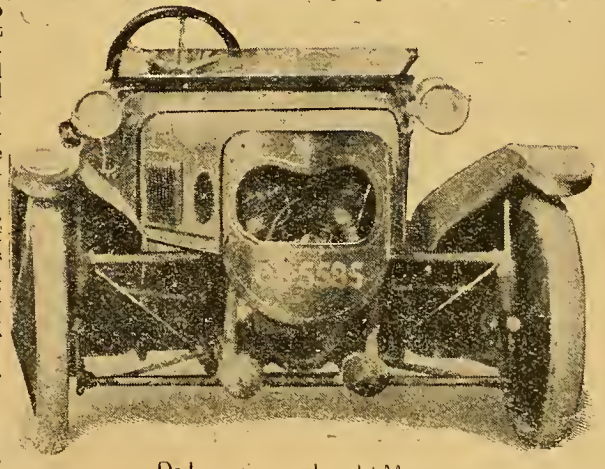
The bodywork for air and water-cooled models forms units with or without the radiator, according to the type of engine used. Three main models are provided, the Grand Prix—a sporting water-cooled vehicle with racy lines—the standard touring model with air or water-cooled engine, and the family machine, which is provided with accommodation for children behind the usual seats. In the latest models a ball thrust has been added to the clutch withdrawal mechanism, longer bearings are fitted to the front wheel steering heads, and much stronger bevels with a different tooth formation are employed.

THE 1920 TAMPLIN.

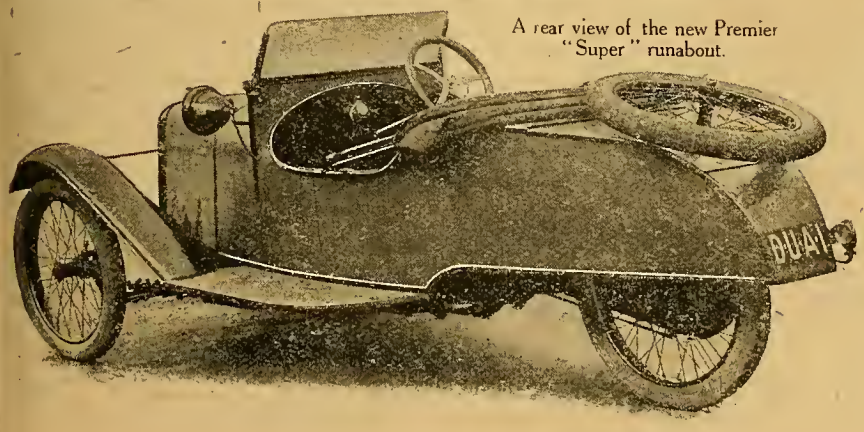
The well known Carden runabout will in future be known as the Tamplin, and a tandem-seated model has been introduced for 1920. The power is provided by an 8 h.p. twin air-cooled engine, the final transmission being by a long belt on either side of the body. It has a very sporting appearance, and should appeal to many.

THE A.V. RUNABOUT.

Closely resembling the pre-war Carden monocar, the A.V. two-seater models come into the category of passenger machines. The engine is located at the rear of the seating accommodation, and the design is probably the simplest form of runabout yet produced. One model is fitted with an 8 h.p. water-cooled twin engine, the other being equipped with an air-cooled engine of a similar size.



De Luxe air-cooled model Morgan.

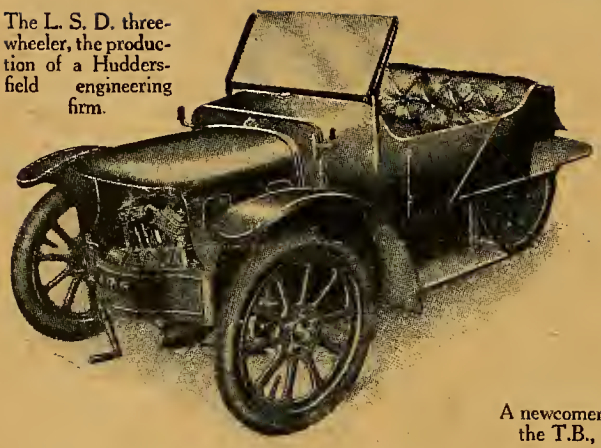


A rear view of the new Premier "Super" runabout.

A NORTH OF ENGLAND THREE-WHEELER.

A new three-wheel proposition will make its *début* to the public at Olympia. This is the L.S.D. cycle car, produced by Messrs. Sykes and Sugden, Ltd., engineers and ironfounders, of Huddersfield—another of those established engineering firms at last turning their attention to the automobile industry.

The engine fitted is an 85.5 × 85 mm. J.A.P. air-cooled twin, placed in front of the axle member and driven by shaft, through a leather-faced cone clutch, to



The L. S. D. three-wheeler, the production of a Huddersfield engineering firm.

a two-speed and reverse gear box located at the rear of the frame.

Quarter-elliptic springs are used at the rear wheel, and a patented system of enclosed coil springs at the front. Dunlop 700 × 80 mm. tyres are fitted on Sankey pressed steel wheels, the rear wheel being readily detachable without disturbing the single chain final drive.

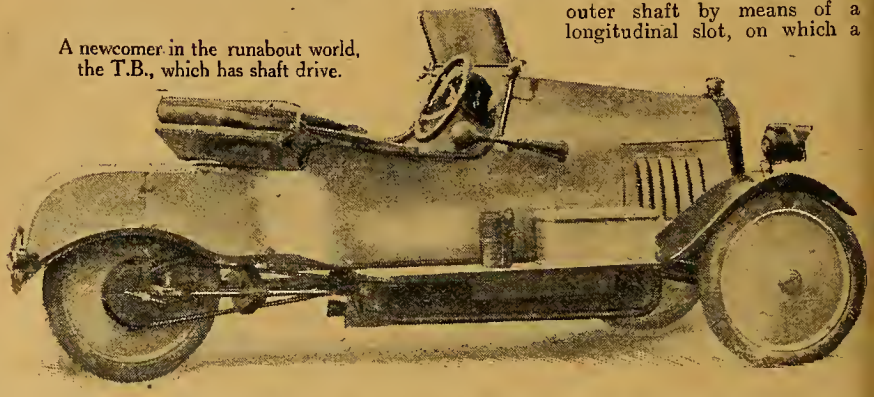
Direct steering by a large diameter wheel, brakes of the external contracting type, and a roomy two-seater body with doors on both sides, are included in the specification. The dimensions are : wheelbase 6ft. 6in., track 4ft., overall length 9ft., width 4ft. 7in., and the price, complete with hood and screen, is 185 guineas.

A NEW THREE-WHEELER—THE T.B.

Several large munition firms have devoted their peace time energies to the motor manufacturing field, and one of these—Messrs. Thompson Bros. (Bilston), Ltd.—is producing a very pleasing little three-wheeler with all-shaft transmission. The T.B., as it is called, has an 8 b.p. engine integral with a two-speed and reverse gear box.

THE BLERIOT WHIPPET.

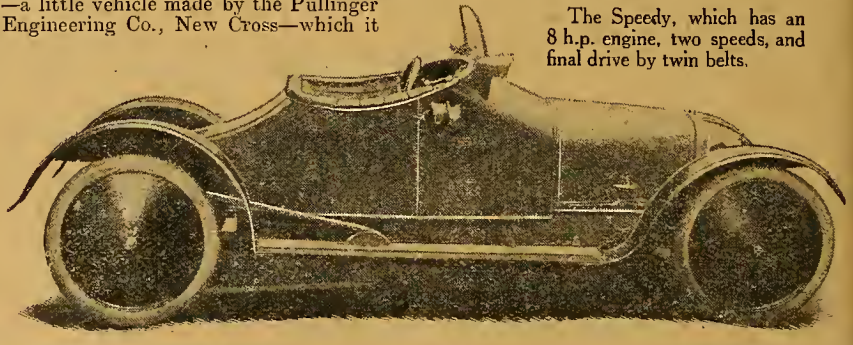
A light and low-priced runabout, produced by a large firm of aircraft engineers, the Blériot Whippet is another small four-wheeler which is in direct competition with the sidecar outfit. The power unit is a Blackburne 8 h.p. twin with outside flywheel and detachable heads. A Ferodo-lined clutch is fitted on the left-hand extension of the crankshaft, and a mechanical starter, by which the driver may start the engine from the seat, is included in the specification. The transmission is by chain to a countershaft, thence by belt to the live axle. Variation in gear ratio is obtained by means of a large variable pulley on the countershaft—an ingenious device which permits the tension of the belt to be kept constant. 700 × 80 mm. tyres and hammock seats form part of the equipment.



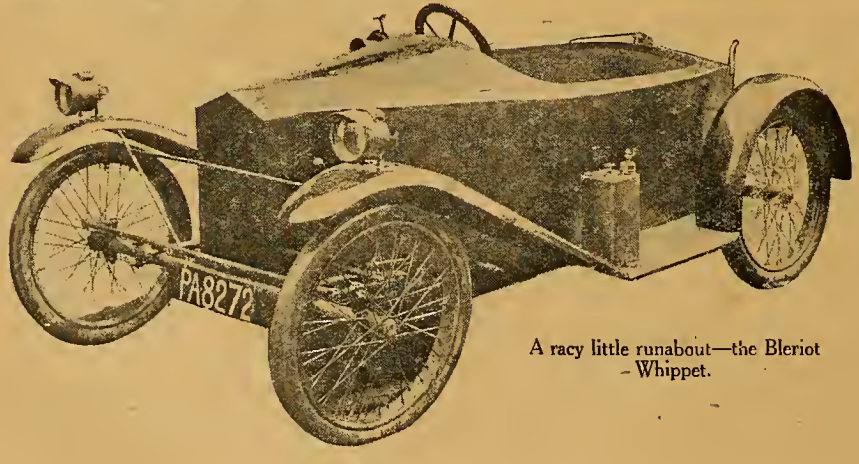
A newcomer in the runabout world, the T.B., which has shaft drive.

THE SPEEDY CYCLE CAR.

One of the few new cycle cars embodying final drive by twin belts is the Speedy—a little vehicle made by the Pullinger Engineering Co., New Cross—which it is proposed to market at a price considerably below that of the average sidecar outfit. It has a simple specification, direct steering being employed, and provision made for an adjustable rake of the steering column. The gear box provides two forward speeds and reverse, the gear change lever being situated in the centre of the floor. The countershaft, driven by chain from the gear box, consists of two separate shafts, one sliding within the other. The outer one, to which is attached the inner flanges of the belt pulleys, rotates on two plain bearings bolted to the longitudinal chassis members. The inner one, however, which carries the outer flanges of the pulleys, is allowed to slide within the outer shaft by means of a longitudinal slot, on which a key on the outer sleeve is fitted. By these means a differential action is obtained automatically on the countershaft by the different speeds of the road wheels on turning a corner. The engine is an 8 h.p. Chater-Lea, having a bore and stroke of 85 mm. = 964 c.c.



The Speedy, which has an 8 h.p. engine, two speeds, and final drive by twin belts.



A racy little runabout—the Bleriot Whippet.

THE L.J. FOUR-WHEELER.

The L.J. cycle car, which was illustrated and described in last week's issue of *The Motor Cycle*, is another of the several little four-wheelers which embody motor cycle practice at several points and sell at a figure approximating to that of the sidecar outfit. The engine is an 8 h.p. J.A.P., which will be offered both in the water-cooled and air-cooled types. The specification includes a pressed steel frame, quarter-elliptic springs, duplex chain transmission, friction disc change-speed, Lynton steel disc wheels, internal expanding brakes, and 700 × 80 mm. tyres. The body is somewhat higher than is usual with cycle cars, and the passengers are thus well protected. The whole car is particularly handsome and will be sold at a figure in the neighbourhood of £200.

Olympia Motor Cycle Show.

ON Monday next, November 24th, there will open at Olympia the most important motor cycle show ever held. There will be more exhibitors and more spectators than ever before, and, in addition, the interest of the individual exhibits will be greater. What shall we see at the Show? This is the question of the moment amongst thousands of ardent motor cyclists, and to some the answer will be disappointing, for, though there are many new firms exhibiting motor cycles for the first time, and though there are a certain number of totally new designs, there is but little alteration in the general run of machines. Some of the more eager spirits have hoped to see a general adoption of aircraft engine practice applied to motor cycles, yet superficially, at any rate, this has not occurred, except in isolated cases. At the same time, more and greater improvements have taken place than meet the eye of a casual observer. A little difference in the design of valve ports and cooling fins is almost indistinguishable externally, but may make a world of difference to the pulling and staying powers of an engine. Lubrication is beginning to take its proper place in the list of important features of design, and several new forms of mechanical or automatic lubrication will be seen.

The size of tyres fitted to all types is on the increase, and, though there are not a great many new converts to the 28in. wheel, it will be found that the sectional diameter of the tyre has increased in a very large number of cases.

Perhaps the most noticeable feature, especially to the keen solo rider, is the fact that, generally speaking, the exhibits can be divided into two main classes: passenger machines and (so-called) lightweights. Many firms will stage machines suitable for solo or sidecar work, but the light solo machine of about 500 c.c. has almost ceased to exist. The reason for this is not far to seek, and blame must be attributed to the public rather than to the manufacturer, for countless people have in the past acquired solo machines to which they have fitted passenger attachments, and then, when troubles have occurred, have blamed the manufacturer for weakness or lack of power.

In spite of (or because of) much criticism in the past, the two-stroke has come to stay, and its exponents are increasing to an enormous extent. It is probably true that the majority of new firms are making small two-strokes, and the success of this type has led one firm to market a 500 c.c. air-cooled two-stroke for sidecar purposes. As price is one of the governing factors in motor cycle sales, and two-stroke engines are cheaper to build than four-strokes, this increase is likely to continue.

Prices.

THE prices of motor cycles have been steadily rising, and grumbles are heard on all sides, yet the grumblers are unjust, for few articles, either manufactured or in the raw state, have risen in price so little as a motor cycle. Anyone who considers for a moment the rise in wages, material, fuel, etc., will immediately realise that the price of motor cycles is justified, and is even likely to rise again in the near future, and those who are unwise enough to delay purchase till prices drop are likely to be without a mount for several seasons.

On the other hand, the money spent on a motor cycle at the present moment is a good investment, for the buyer may be reasonably certain of a good return when selling his machine when the time comes to dispose of it.

Prospective car purchasers were surprised by a sudden jump in prices during the recent Olympia Car Show. Is this to be repeated in the motor cycle world? The question is a difficult one, but though we consider that there will be a steady increase in prices to at least 100% on pre-war prices, it is doubtful whether there is at present any excuse for a considerable rise above this figure.

An Index to the advertisements in this issue will be found on the page facing the back cover.

Ancient and Modern Lightweights.

A LONG letter from a Buxton reader has reminded me of a fundamental difference between the type of lightweight which figures in a modern Six Days and those which some of us used to ride a dozen years ago. The lightest machine in the A.C.U. week was a 2¼ h.p. Radco, scaling 170 lb. In 1905 my correspondent built a 3½ h.p. machine with a Peugeot twin engine, and the outfit weighed no more than 150 lb. exclusive of fuel and lamps. About the same date I possessed a 7-9 h.p. Peugeot-engined 'bus, which with empty tanks weighed no more than the 1919 Radco; and, unless I am much mistaken, Mr. E. Kickham, of Bristol, owned an even lighter sample. In other words, specifications have become so complex that a 1919 2¼ h.p. machine is heavier than the high-powered sporting 'buses of twelve or fifteen years ago. If the much-talked-of "Single Gear Club" ever materialises, we may evolve one or two skilful assemblers, who will revive really light one-speeders for enthusiasts. Those makers who still list a single-geared machine naturally employ most of the parts which figure in their heavy three-speed sidecar pullers, and the consequence is we cannot buy single-speeders of the old type.

A Man of Ideas.

THE correspondent referred to is certainly a man of ideas. Some ten years ago he helped to build a machine with a very curious frame, consisting principally of six small diameter tubes running from the steering head to the back hub. The two lower tubes dipped to carry the engine, whilst the remaining four ran straight. He claims that owing to vertical "give," coupled with lateral rigidity, this frame was as comfortable as any spring system ever devised, whilst it was immune from side-slip. Some day he hopes to construct a drive consisting of a Whittle belt running over four pulleys, viz., two engine-shaft pulleys, one countershaft jockey pulley near the bottom bracket, and one belt rim. The belt runs over one engine pulley, back to the jockey pulley, and then forward to the other engine pulley, and so to the belt rim. This drive has been tried out, and is alleged to be non-slipping under any load; the fact that the run is out of alignment does not appear to matter. The next paragraph details yet another idea of his with which readers may care to experiment.

More Weight on the Front Wheel?

VERY few of us have ever investigated the percentages of the total weight which are carried on the front and rear wheels respectively. The engine is usually carried pretty well forward; but it must just about be balanced by the preponderance of other dead loads further aft—gear box, kick-starter, carrier, tool bags, etc.; and the rider, who scales far more than a couple of ordinary engines would weigh, is seated well astern, and generally uses a type of riding position which throws his weight well back. My correspondent is a heretic in these matters. He prefers to stack his tools and luggage over the *front* wheel, and says that when this is done a vast improvement in comfort usually results. He doubts whether a spring frame is a necessity if the weight be apportioned as he recommends. I hesitate to print this theory, for fear some of the pillion enthusiasts should take to carrying their flappers on front wheel tan-sads.

Maintenance of Tune.

IN ninety-nine cases out of a hundred, if a machine performs better at the end of a Six Days Trial than at the beginning, it is an excellent 'bus. Here is the exception which proves the rule. Many years ago I entered for a Six Days. The previous week I met the works manager at a hill-climb. "Let me take your 'bus back to the works to-night. We'll see she is all right, and rail her up to you at X——." I agreed. When I recovered the machine at X—— on the eve of the trial, it would hardly move. The fools had rebushed everything, and it was very tight. The engine seized twice during the trial, but I accomplished prodigies of speed repairs and endurance, and got my gold. By the end of the trial, the machine was very appreciably faster: some 15 m.p.h. faster on the flat, and under any conceivable "maintenance of tune" test I should have scored a lot of marks. But it took me all my time to get it back to the works by road. Sloppy would be a mild description of the principal bushes: in particular, I remember that, in unseizing against time on the road, I had sheared the tips off the teeth of a timing pinion, and the bits of metal had ground a lovely pattern on the flywheels. This reminiscence indicates that even a flying mile at Brooklands on the first and sixth days of a trial is not a sure test, unless a standard minimum speed is imposed in each class. The pitfalls of competition organisation are innumerable.

Sidecar Golds in the Six Days.

THE firms and individuals who are justly proud of the gold medals gained by their sidecar outfits in the 1919 Six Days Trials have forgotten a little ancient history. As long ago as 1912 a 499 c.c. Triumph outfit won a gold medal in the Scottish Trials, and a magnificent performance it was. The rules may not have been as stringent as they are nowadays, and it was not essential for every hill to be climbed with the crew on board. On the other hand, the course was longer and more exacting than the Llandrindod Wells route, and included the terrific ascent of Amulree from the Kenmore side. The pilot of the outfit in question was a well-known sporting parson, the Rev. P. W. Bischoff, who has been lost to motor cycling circles for the past year or two, owing to his duties on board H.M.S. *Glorious*—one of the famous "hush-hush" cruisers. His passenger

easional Comments.—

as a lady, who has since become Mrs. Bischoff, and ho, under her maiden name of Miss Beatrice Lang- on, was not without a motor cycling reputation of er own. I hear rumours that an interesting announce- ient about the Rev. P. W. Bischoff's motor cycling ctivities may be expected shortly. In the meantime, ironiclers should note that Mr. Bischoff won the first old awarded to a single-cylinder sidecar outfit in a ix Days Trials, and that he won it with a 499 c.c. ngine, and not with a "big four."

Speedman's Wobble.

FRANKLY, I am not impressed by the explanations of speedman's wobble which various correspondents have sent in, and my personal opinion that both the cause and the remedy are still to be iggested. Gyroscopic action, wheels out of track, idden closing of the throttle, unbalanced wheels, and olding the handle-bars too tightly, have all been put orward as probable causes. I can provoke it on ertain machines with the wheels in track and balanced, uring acceleration, and whether I hold the bars ghtly or loosely. Not being a No. 8 hat, I am illing to sit at anybody's feet when gyroscopes are eing discussed, but I note that the gyroscopic mer- iant goes out of his way to say that a speed-wobble iachine will speed-wobble at full r.p.m. on low gear. am afraid this is not true. Not many moons since tested the point on a single. I got a wobble full revolutions on top gear which cured me of any esire to try another wobble for weeks, but the machine as easily steerable when all out on its intermediate ears. I am as far from understanding the phenome- on as ever I was, but all my observation leads me to ncy that three factors are present in each case, viz.:

(1.) A very high road speed.

(2.) An extraneous fac- r to start the wobble ossibly a small pot-hole). achines which are apt wobble do not always obble.

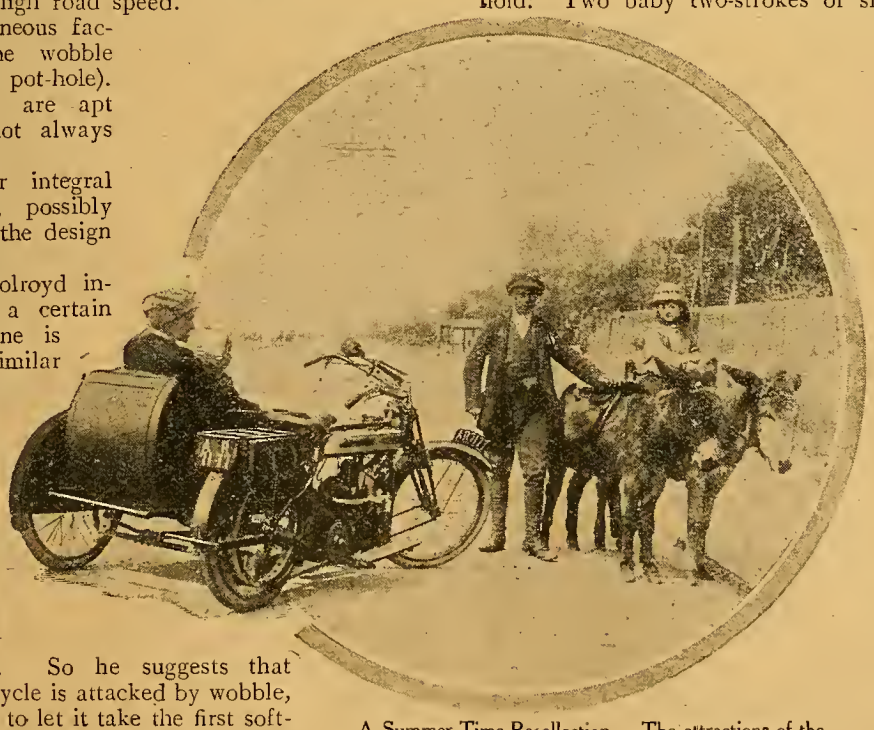
(3.) A factor integral the machine, possibly me element in the design the steering.

Mr. Victor Holroyd in- rms me that a certain pe of aeroplane is bject to a similar henomenon. he only thing do when it ays this trick to let it de- ribe its radius; the pilot ttempts to raighten the achine, his te is a fore- one conclusion. So he suggests that hen a motor bicycle is attacked by wobble, may be as well to let it take the first soft- oking bit of roadside that comes along, lest orse should happen later, when the machine gets absolutely and entirely beyond the control of the rider.

I have emerged scathless from these wobbles (with a greatly accelerated pulse) on perhaps a score of occasions; and I should only take Mr. Holroyd's heroic advice under sheer compulsion. But here is a chance for the A.C.U. Let them get a variety of speed-irons; a cylinder of compressed air; an inflatable rubber suit; a stretch of wide seashore; and one of their crack henchmen. Station Professor Boys or Dr. Low handy with cinematographs, and record exactly what does happen. Such an experiment would be more valuable and far more interesting than the C.D.T. What does Mr. Loughborough say?

Guaranteed Maximum Weight.

I AM rather surprised that no firm has yet started guaranteeing the maximum weight of its stock machines. This stunt would be of great advertising value, provided that the maximum weight was moderate. In the old days people were less particular. But nowadays motor cycling has acquired the dignity of a history: and a history implies that there are veterans amongst us. Lots of living men have ridden for ten or fifteen years, and they not all amassed fortunes and bought cars. They are still faithful to the humble two or three-wheeler, and are less nimble than they used to be. *Ergo*, they dislike unnecessary weight, especially on solo machines. Of course, when our ideas of "production" were limited to bending up two machines per week by hand, the individual weights of machines which were nominally duplicates might and did vary by as much as 10 lb. When scientific production crept into a few factories, there was not much weight difference between two rival machines of the same size and type. These conditions no longer hold. Two baby two-strokes of similar specification may differ in weight by 50 lb. In the bigger classes the discrepancies are still more marked. Writing without a scales test, I fancy that the limits of variation in the three-speeded $3\frac{1}{2}$ h.p. class exceed a hundredweight—that the lightest example of the type is barely over 200 lb., while the most weighty approach 3 cwt. This being so, would it not pay the makers of the less heavy motor cycles to print guaranteed catalogue weights for their stock machines?



A Summer Time Recollection. The attractions of the most elaborate sidecar outfit pale before the fascination of the humble seaside donkey.

AN OPEN LETTER TO THE TRADE.

By B. H. DAVIES.

GENTLEMEN, I am credibly informed that an ancient book exists in which there occurs a curious maxim that the poor are blessed. If I were offered wealth in a portable form, such as a sack of diamonds, this passage might puzzle me. But when I regard your wealth under present conditions, I rejoice that I am a pauper. To have £500,000 sunk in land, buildings, plant, and raw material; to be repeatedly held up by strikes, faulty stuff, shortage of some essential component and the like; to be paying out thousands per week in wages, whilst next to nothing is coming in; to be browbeaten by your agents and customers, all of whom want instant deliveries; to be bombarded with requests for spare parts dating back to 1906, all of which were mislaid when you switched over to bombs or shells, or aero engines in 1915—well, despite your war profits, my heart bleeds for you. I am half afraid of meeting you at Olympia. I shall still no doubt see the fur coat and the big cigar (yes, I still smoke, thank you), but I shall note grey patches on your temples and a few reefs in your waistbands. In all seriousness, gentlemen, you have had a very mouldy time during the last twelve months; most of us understand, and are doing our best to be patient.

Prices.

I dare not omit the thorny subject of prices, because motor cyclists are so excited about it. May I advise you to address riders after the time-honoured fashion of paterfamilias when sonny is flat across his knee and the strap is getting up its revs.—"it hurts me more than it does you"? When I enter your showroom and buy a motor cycle, you tell me I may get it in March, but I may not get it till September; that the catalogue price of, say, £125, is what Parliament calls a token estimate—when the invoice comes along, it may be £150, but should prices fall, of course . . . (well, they never fall, do they?) This is very trying for us buyers; why don't you use your double-page advertisements to win our sympathy, for you are buying land, labour, tools, and material on the very same system: the worry of my petty little £125 transaction is a fleabite compared to your big deals for unknown delivery at an unknown price. Under the circumstances you have done well in keeping your prices where they are. No motor bicycle has yet gone up 100%; there is hardly another commodity on the market which has not risen at least 125%. Your foes say you have made absurd profits before the war; I prefer to believe that you have intensified the efficiency of your works and cut your manufacturing costs a little. I do not believe we have any cause to grumble.

In this connection, is it impertinent to remind you that the days when any old thing on two wheels can be sold for upwards of £60 will not last for ever? Before we are much older, supply will overtake demand. Then there will not be room for all of you. The survivors will be those, and only those, who turn out really good machines by first-class "production" methods. The trade will tend to become concentrated in a few hands; we shall hear of combines and amalgamations. Most of the small makers will disappear. 1922 at the latest will hear several swansongs, I fancy.

Comfort.

The war seems to have put the strong, simple machine on a pedestal. Nothing did better than our old friend the single-cylinder, in its choicest forms. The D.R. experience only confirms what every provincial agent could have told us. For sheer, hard utilitarian work, the man who knows selects a heavy single-cylinder of the best class. Believe me, gentlemen, this is only a phase. For many years the car owner who wanted a 'bus for prolonged hard work bought a single-cylinder De Dion chassis, not because that tough little animal was the ideal of refinement, but because it was a lot better than the average multi-cylinder. But you cannot sell single-cylinder cars now; and sooner or later the day must come when a more refined type of motor bicycle will be as economical and trustworthy as the bulldog singles have proved in the war. It is easy to smile at the ambitions of young engineers who outrage every convention, and try to breed motor bicycles by crossing a Sopwith one-and-a-half strutter with a Dursley-Pedersen push bicycle, or some such novel pedigree. But straws show which way the wind is blowing. There was a time when the single-cylinder ideal absolutely dominated the British market. Then various unconventional machines came along and stole a slice of your monopoly: the Douglas took the first bite: then the Scott had a mouthful: presently the big American twins started to nibble: and now the scooter is making a bid for popular favour. Each of these little invasions is a writing upon the wall. We need to appreciate their separate significances. We must never forget that despatch riding in Flanders has few affinities with joy riding in Shakespeare's country. Reliability and economy are the foundations of the motor cycle market; but to-day sees an almost equal emphasis laid upon *comfort*. Different riders place various interpretations upon that word comfort. But its importance is growing daily, as your original supporters grow elderly, as the sport ropes in so many ladies. We shall not go far wrong if we admit that the modern demand is for a quiet, vibrationless

An Open Letter to the Trade.—

machine, which affords its driver ample protection from dirt and weather, and is easily cleaned. In this direction we have still a long furrow to hoe.

Transmission.

It would be grossly unfair not to emphasise the fact that you are making vast progress. Your engines keep quite astoundingly cool; time was when a hill which kept us on a low gear of 7 to 1 for half a mile was worrying; to-day a sidecar man has no qualms in racing his engine on a gear of 16 to 1 for a mile or more. Your gear boxes hardly ever give any trouble. Your chain drives have parted with their old harshness, even on high compression singles: I am even now riding a T.T. chain-driver, capable of over a mile a minute, and I have *never* "felt" its drive. The new dynamo lighting has robbed the darkness of its terrors; honestly, I believe night riding is now safer than daylight work; the chiaroscuro of the brilliant beam against the black night gives superb vision, and the beam clears the road even at a blind corner better than any nightingale whistle or Klaxon. You have begun to sympathise with the duffer who found hand lubrication a bore. Several of you have incorporated an oil sump on car lines in your 1920 models. Their success remains to be demonstrated, but I have no reason to mistrust this departure. The old system was really rather absurd. On our tiny engines with their small loads we have contentedly used a quart of oil every 100 miles for twenty years. We buy a good car, scaling maybe a ton, and we find that a quart of oil will last from 250 to 750 miles. So we naturally welcome this departure, and the redesigned bearings and cylinders and pistons which promise to eliminate the need for "oil-cooling."

Spring Frames.

Makers as a class are rather slow to adopt the spring frame. One of your brightest personalities tells me that the spring frame is the hardest technical nut to crack in the whole of your job. I can quite believe him; and the subject is pretty well hedged in with patents nowadays. But, gentlemen, it is a thousand times worth doing. Let me frame you a parable. Do you think a Rolls-Royce car would be cheap to run or reliable if it were restricted to solid tyres? If Napier, Daimler, and Vauxhall cars were sold with cushion tyres, and Renault, Fiat, and Delage with pneumatics, which trio would be in more demand? There are bad spring frames in existence—expensive to make, weighty to an absurdity, and deficient in the purpose of their being. But there are spring frames which cause a rigid frame—aye, the best rigid frame—to remind one of the old solid tyre; and roads are not good—may never be good again, for we are now too poor to reconstruct roads on the grand scale, and the era of motor lorries has opened.

Sidecars.

Perhaps the sidecar is the brightest star in the trade crown. Fundamentally unmechanical, it confronts the designer with a thousand snags. Its origin and its survival are alike due to the immortal demand for something which will transport two people as cheaply as possible. You choked down your engineering conscience, you accepted the commercial situation, and you have deified this monstrous abortion. In the Llandrindod Trials we saw your latest combinations soaring easily where no self-respecting car would desire to go. In the teeth of a most unholy alliance of cross stresses and illegitimate vibrations you have endued these misbegotten three-wheelers with a staunchness and tenacity which a first-class car at ten times their price might envy. Although the available chassis accommodation is so small, and the design creates unparalleled problems in accessibility and the like, you have managed to cram in every luxury for which a fastidious rider can ask, and the result is a model of convenience. I do not think the engineering world can produce an example of greater efficiency evolved under equal handicaps. Just now there are

Competitors in the brake test during the South Birmingham Club's trial for the Sangster Cup

An Open Letter to the Trade.—

signs that mass production air-cooled cars may react on the sidecar in the near future; the prices of the two types of vehicle are narrowing towards each other. I suppose you will retort with mass production likewise; we have never yet had it either in sidecars or in three-wheeled runabouts. I fancy the latter lends itself best to the process—anyhow, at current prices that fourth tyre and wheel represent a notable economy, and give you your chance.

I had almost forgotten the dear little scooters. It is too early for me to dogmatise about them: some of their designers are Cassandras in trousers. One thing is evident. The scooter has caught the fancy of a stratum of the population which regards all other motor bicycles with a cold, fishy stare. If, as is quite possible, some of the pioneer scooters do not wholly fill the bill, it should not be difficult to evolve a specification which will please the new public. You have secured the attention of thousands of new customers; grapple them to your souls with hooks of steel. The existing scooters may be all that is wanted; if not, 1921 must bring along the super-scooter. The scooter's attraction lies in its cheapness and low weight. We will not deny that the great foolish B.P. imagines that a scooter is simpler than, *e.g.*, a Triumph touring machine. Of course, it is not really. It naturally has no clutch or gear box, but those items do not give trouble. It tickles the ignoramus because it is not a mass of naked machinery, as most motor bicycles are, and reminds him of a car in that it conceals its works. Take the tip, gentlemen, and give us tourist machines, with all their works out of sight; they will appeal to the unmechanical amateur and to the fair ladies.

Cleanliness.

That brings me to a detail upon which I regret to state you are excessively obstinate. Very little has been done as yet either to assist a motor bicycle to keep itself clean or to facilitate cleaning it when it has got into the unholy mess to which usage always reduces it. I have not had time to clean my own machine for a week or two. It is caked with filth from end to end, and I estimate that, if I wanted to cut a decent figure on it to-morrow, or to make a convert with its aid, or to unload it on a buyer, three hours of excessively hard and begriming labour would be necessary. Have you despaired of "clean" sport? Twenty years ago it was unthinkable that car driving could ever be a clean job. An old friend of mine used to carry an enamel wash-basin, a scrubbing brush, and a tin of soft soap inside the bustle of his 3½ h.p. Benz. We used to furbish up before we rang the bell at our destination, and our hosts would say, "Why, you do not look as if you'd been *motoring!*" To-day I slip a dustcoat over my evening dress, put on washleather gloves, and drive out to dinner in an open car, arriving at my destination spotless. Some day, perhaps, you will give the motor cyclist similar facilities. As a stepping-stone on the road, why not give us machines which can be swabbed down with a hose and a lump of waste?

So much for ideals. I am asked to press upon you one very humdrum detail—the standardisation of controls. You know all about it. There is no reason why you should not establish this change by the 1920 Olympia. The need is serious. Your failure to accomplish this necessity kills a few people every year.

The "Ford."

In conclusion, may I commend to your notice the "Ford" motor bicycle which is the pet craze of one of my colleagues? It is not for us to say that it is possible—that rests with you. But, to quote pre-war price standards, we feel humiliated to think that Henry Ford could sell a 20 h.p. four-seated car at £77 f.o.r. Detroit, and that our own industry has never turned out a medium roadster motor bicycle at less than £50. We notice that you got down the price of a popular push bicycle to eight guineas by the equivalent of mass production, and we know that no firm in the industry has ever turned out more than some 6,000 machines a year. It looks as though a simple roadster motor bicycle could be produced in vast quantities at a considerable reduction on present figures. If so, it ought to be done at once. The hours of labour are shortening. The wages of labour are rising. Thousands of artisans have no real out-of-door hobby. There comes an age at which footer and cricket cease to satisfy. Watching games is not particularly wholesome. Gardening does not appeal to everybody. The open road is the best cure for the maladies of Bolshevism.

Its Political Aspect.

If you made it possible, as you could do, for every steady and efficient artisan to renew his wasted tissues on the road at week-ends and in summer evenings, you would find labour much easier to handle. In your business relationships you occasionally have to deal with men who work hard and have no healthful hobby. They are not the easiest fellows in the world to deal with, and you know why. "The colonel's lady and Judy O'Grady are sisters under their skins." If your sandblastman got the three rounds of golf which keep you sane every week, he would not savour of the I.W.W. heresies, as he now does. He would recognise you as a man and a brother. Well, golf is not in his line; but you could make it possible for him to take the wife and the twins down towards Wales every sunny week-end if you turned out a simple 4 h.p. at the rock-bottom commercial price which scientific production makes possible. He will not work. He has got the curtailed output maggot in his brain. Was it not Lowe who said when the Reform Bill passed, "We must educate our masters"? He has been largely educated by a propaganda which contains not a little rubbish. It is up to men who know facts and have been blessed by a costly education, to organise a counter-propaganda based on facts.

Wishing you a very prosperous winter, with a swift return to happier conditions in every respect,

Yours very faithfully,

B. H. DAVIES.

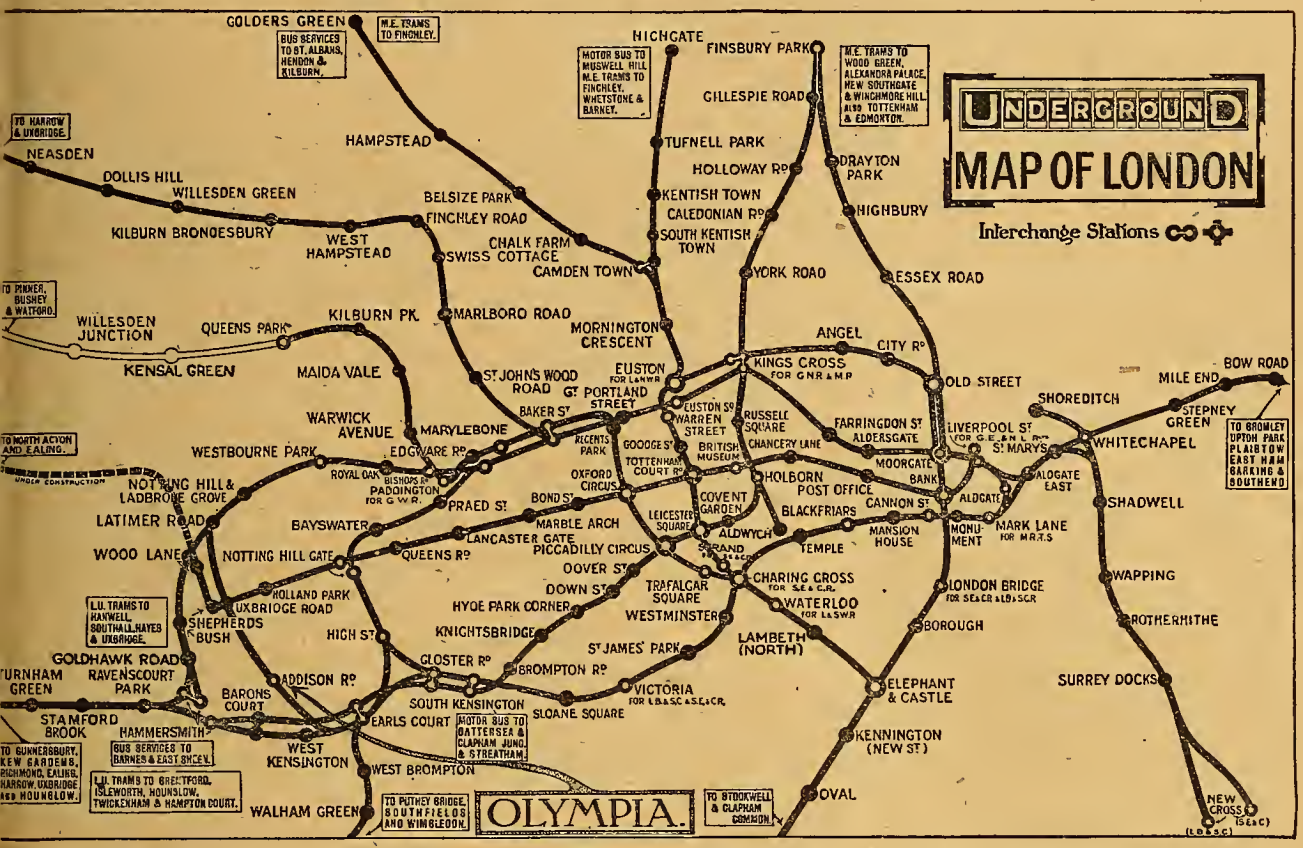
THE MOTOR CYCLE SPECIAL NUMBERS.

NOV. 27th — This issue will contain a detailed and fully illustrated stand-to-stand report of the Olympia Show, and will be on sale at the Exhibition.

DEC. 4th. — Review of Sidecars, Accessories, and Tyres. Impressions of the Show.

HOW TO GET TO OLYMPIA.

Details of Tube and 'Bus Routes to Olympia.



FOR the benefit of our readers who are complete strangers to the Metropolis we have prepared the following table, showing how Olympia may best be reached by Underground from the London main line termini.

By Underground from the Main Line Termini.

BAKER STREET (Metropolitan Ry.). By Bakerloo line to Charing Cross; thence by District Railway to Addison Road, changing at Earl's Court.

BROAD STREET (L. & N.W. Ry.). By Central London Railway to Addison Road, changing at Shepherd's Bush; or by motor 'bus—Nos. 49 and 49a—from Shepherd's Bush station.

CANNON STREET (S.E. & C. Ry.). By District Railway to Addison Road, changing at Earl's Court.

CHARING CROSS (S.E. & C. Ry.). By Hampstead line to Charing Cross; thence by District Railway to Addison Road, changing at Earl's Court.

EUSTON (L. & N.W. Ry.). By Hampstead line to Charing Cross; thence by District Railway to Addison Road, changing at Earl's Court; or by L. & N.W. Ry., changing at Willesden.

FENCHURCH STREET (L.T. & S. & G.E. Rys.). By District Railway from Mark Lane Station (3 minutes' walk) to Addison Road, changing at Earl's Court.

KING'S CROSS (G.N. Ry.). By Piccadilly line to Addison Road, changing at Earl's Court.

LIVERPOOL STREET (G.E. Ry.). By Central London Railway to Addison Road, changing at Shepherd's Bush; or by motor 'bus—Nos. 49 and 49a—from Shepherd's Bush station.

LONDON BRIDGE (L.B. & S.C. & S.E. & C. Rys.). By City and South London Railway to Addison Rd., changing at Elephant and Castle, Charing Cross, and Earl's Court.

MARYLEBONE (G.C. Ry.). By Bakerloo line to Addison Road, changing at Charing Cross.

PADDINGTON (G.W. Ry.). By Bakerloo line to Addison Road, changing at Charing Cross.

ST. PANCRAS (M. Ry.). By Piccadilly line to Addison Road, changing at Earl's Court.

ST. PAUL'S (S.E. & C. Ry.). By District Railway to Addison Road, change at Earl's Court.

VICTORIA (L.B. & S.C. & S.E. & C. Rys.). By District Railway to Addison Road, changing at Earl's Court.

WATERLOO (L. & S.W. Ry.). By Bakerloo line to Charing Cross; thence by District Railway to Addison Road, changing at Earl's Court.

By Motor 'Bus from the Main Line Termini.

For the benefit of visitors who desire to take a 'bus to Olympia, a list of the 'bus services from the main line stations has been prepared as follows:

BAKER STREET (Metropolitan Ry.). 'Bus service No. 27—Highgate to Twickenham.

BROAD STREET (L. & N.W. Ry.). No. 33a—Liverpool Street and Hounslow, No. 9—Liverpool Street and Barnes.

CANNON STREET (S.E. & C. Ry.). No. 13—London Bridge and Hendon to Piccadilly Circus; thence by No. 9—Liverpool Street and Barnes, or No. 33—Charing Cross and Richmond.

CHARING CROSS (S.E. & C. Ry.). No. 33—Charing Cross and Richmond, No. 9—Liverpool Street and Barnes.

EUSTON (L. & N.W. Ry.). No. 73—Stoke Newington and Richmond.

FENCHURCH STREET (L.T. & S. & G.E. Rys.). No 23—Leadenhall Street to Oxford Circus; thence by No. 73.

KING'S CROSS (G.N. Ry.). No. 73—Stoke Newington and Richmond.

LIVERPOOL STREET (G.E. Ry.). No. 9—Liverpool Street and Barnes, No. 33a—Liverpool Street and Hounslow.

LONDON BRIDGE (L.B. & S.C. & S.E. & C. Rys.). No. 13—London Bridge and Hendon, or No. 13a—London Bridge and South Hampstead to Piccadilly Circus; thence by No. 9—Liverpool Street and Barnes, or No. 33—Charing Cross and Richmond, or No. 33a—Liverpool Street and Hounslow.

MARYLEBONE (G.C. Ry.). No. 27—Highgate and Twickenham.

PADDINGTON (G.W. Ry.). No. 27—Highgate and Twickenham.

ST. PANCRAS (M. Ry.). No. 73—Stoke Newington and Richmond.

ST. PAUL'S (S.E. & C. Ry.). No. 9—Liverpool Street and Barnes from New Bridge Street, or No. 33a—Liverpool Street and Hounslow.

VICTORIA (L.B. & S.C. & S.E. & C. Rys.). No. 16—Victoria and Cricklewood, or No. 25—Victoria and Seven Kings, or No. 38—Victoria and Walthamstow, to Hyde Park Corner; thence by No. 9—Liverpool Street and Barnes, or No. 33—Charing Cross and Richmond.

WATERLOO (L. & S.W. Ry.). No 1—Tower Bridge and Kilburn, No. 1a—Tower Bridge and Hendon, or No. 63—Chalk Farm and Tulse Hill, to Strand; thence by No. 33a—Liverpool Street and Hounslow, or No. 9—Liverpool Street and Barnes.

NO. 33a—HOUNSLOW AND LIVERPOOL STREET. *From Hounslow via London Road:* Richmond Road, Isleworth, St. Margaret's Road, Richmond, Sheen Road, Upper Richmond Road, Castelnau, Hammersmith, Olympia. *From Liverpool Street via Bank:* Cannon Street, Ludgate Circus, Strand, Charing Cross, Piccadilly High Street (Kensington), Olympia.

NO. 49—SHEPHERD'S BUSH AND STREATHAM COMMON.—*From Shepherd's Bush via Holland Road:* Olympia. *From Streatham Common via Tooting Bec Road:* Trinity Road, Northcote Road, Falcon Road, Battersea Bridge, Sydney Street, Gloucester Road, High Street (Kensington), Olympia.

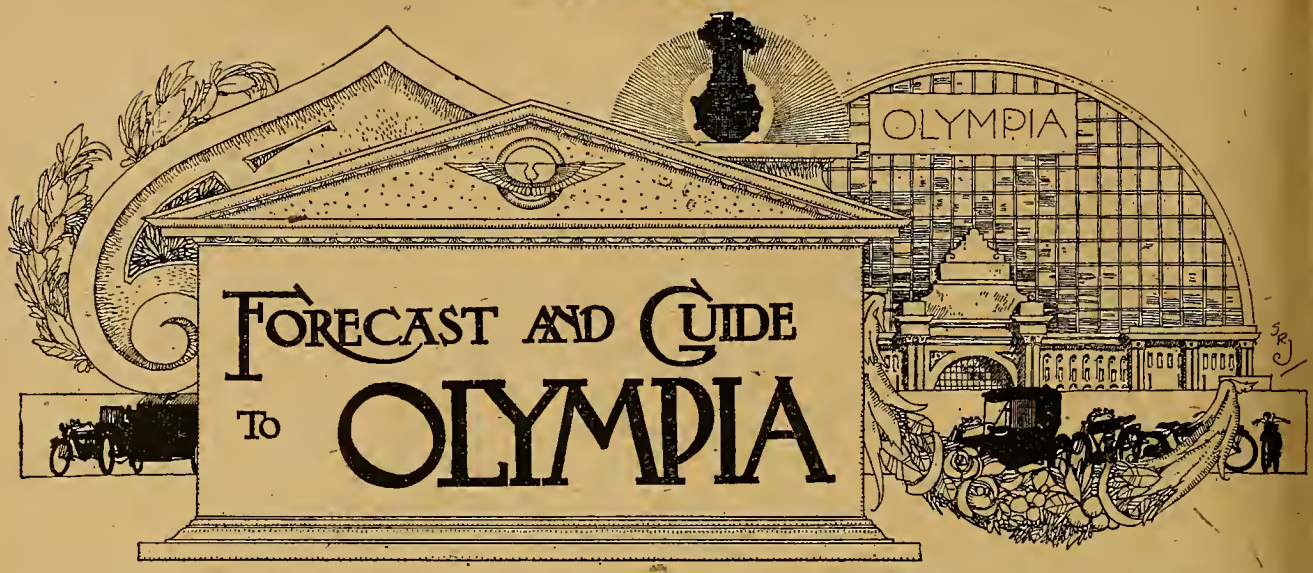
Plan of Gallery, where all the accessory and equipment exhibits will be found.



FORECAST AND GUIDE TO OLYMPIA

In last week's issue we gave particulars and illustrations of 70 passenger machines which will be marketed next year, most of which will be exhibited at the Cycle and Motor Cycle Exhibition at Olympia next week. The following pages contain a stand-to-stand forecast of the exhibits. Plans showing the positions of exhibitors are also contained in this issue, and in "The Motor Cycle" dated November 27th a full description of the motor cycle exhibits will be published. Sidecars and Accessories will be dealt with in detail in the issue for December 4th.

Stand **WHIPPET SCOOTER.**

1a. Many designs of scooters have been produced during the present year, but few are fitted with engines specially designed for them. The Whippet is one, however, the power unit being an exceptionally neat "job." Of 1½ h.p., it is of the four-stroke type, having overhead valves, an aluminium cylinder with a steel liner, an outside flywheel, and a detachable head. The last mentioned is held in position by four long bolts. An aluminium piston of unusual design, and having two rings, is used. Lubrication is by splash feed from a hand-pump on the tank, which, in addition to oil, contains one and a quarter gallons of petrol. The frame is of duplex construction throughout, and is fitted with domed guards. External contracting brakes are fitted to both wheels, one being operated by a pedal.

Stand **ALECTO.**

15. The Alecto motor cycle is one of the new propositions introduced by newcomers to the motor cycle industry, Messrs. Cashmore Bros., of Balham, and is a two-stroke of 350 c.c. capacity nominally rated at 3½ h.p. The engine has a bore and stroke of 76 mm. and is of the three-port type, but possesses several features of interest. In the transfer passage there is a plug 1¼in. in diameter, by the removal of which easy access to the ports is obtained for cleaning purposes. The exhaust has twin outlets, each pipe being 1¼in. in diameter and leading to a large silencer of the barrel type, from which the exhaust gases pass through a long tail pipe 1½in. in diameter. A release valve of the mushroom type is located immediately above the twin exhaust flange into which the released gas passes by way of a small tube.

An aluminium alloy piston is used in a cast iron cylinder which has deep fins; the crankshaft and connecting rods are made of stampings of high tensile steel, the flywheel being a mild steel stamping.

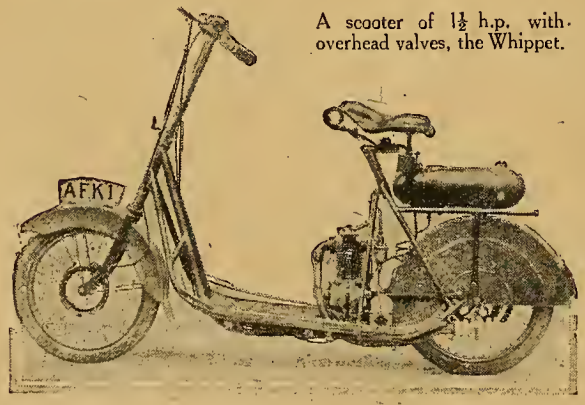
Large double-row Skefko ball bearings support the crankshaft in the crank case in addition to long white metal bearings of the plain type. The connecting rod big end is of the split variety and is white metal lined.

A noteworthy feature of the machine is the method of supporting the power unit in the frame. This is by means of a substantial cradle upon which are carried the complete unit, including silencer and also the footboards and brake pedal.

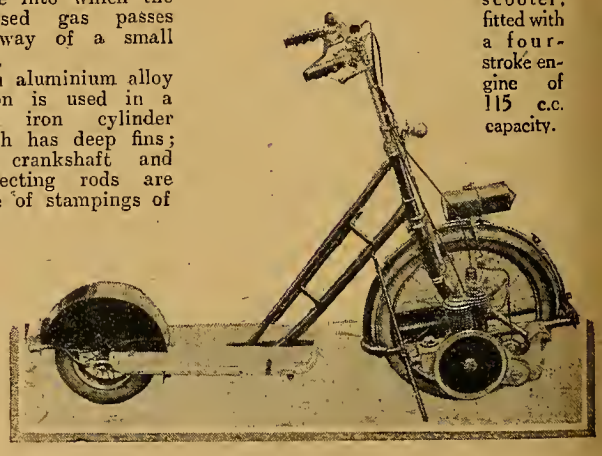
Stand **SANDUM SIDECARS.**

15a. Many new sidecar designs, the products of the Sandham Engineering Co., were described in a recent issue of *The Motor Cycle*, amongst them being two models which are capable of being converted to accommodate two persons. Important developments in these models, however, have followed, and a much improved pattern will be exhibited.

The chief feature of the latest two-seater model is that, although similar in shape and only a few inches longer than the single-seater, ample leg room, com-



A scooter of 1½ h.p. with overhead valves, the Whippet.



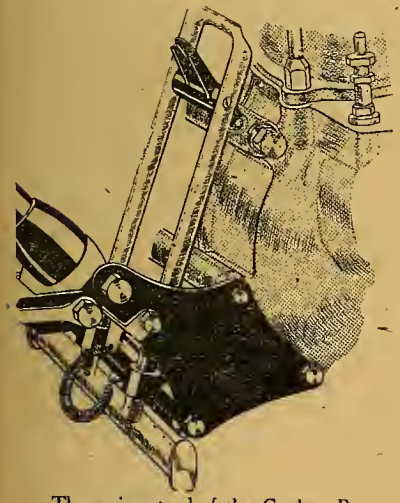
The Silva, scooter, fitted with a four-stroke engine of 115 c.c. capacity.

Forecast and Guide to Olympia.—

bined with the maximum of comfort for two persons, can be provided in a few seconds. The additional seat has a collapsible backrest, which, when not required, is folded over the seat, and, by passing the strap provided around both these components, the seat is inverted and the flange screwed thereto allows the complete fitting to be housed in the front of the body. The bottom of the seat, being flush with the top of the body, completely conceals its location. When it is required to take two passengers, the seat is withdrawn, and, by engaging the studs on the underside of it with holes in a wooden ledge screwed to the sides of the body, the seat can be adjusted to suit the passenger. Foot room is provided for the foremost passenger by dropping the hinged nose of the body, and for the rear passenger by the well sunk in the floor of the sidecar.

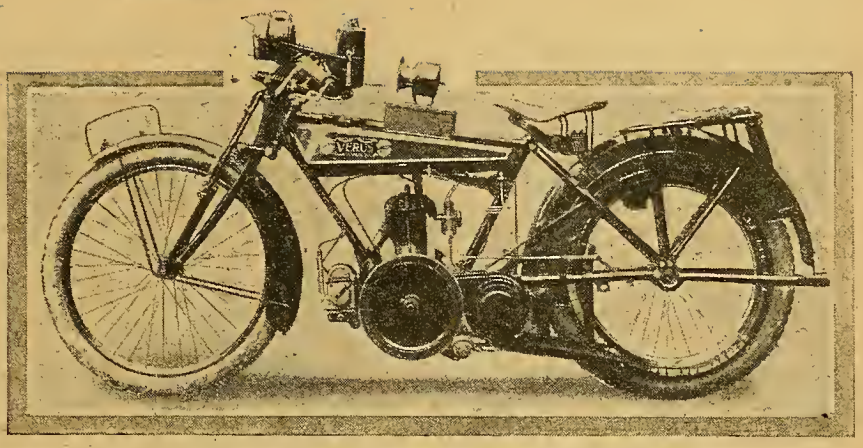
Stand **COULSON.**

16. Three models of Coulson motor bicycles will be exhibited by the F. Aslett Coulson Engineering Co. One of them is a 4 h.p. sporting model fitted with a 4



The spring stand of the Coulson B. motor cycle.

h.p. Blackburne engine, single geared, and equipped with the excellent spring frame which has proved so successful during the present year. It is an attractive mount, which should appeal to those who prefer a simple solo single.

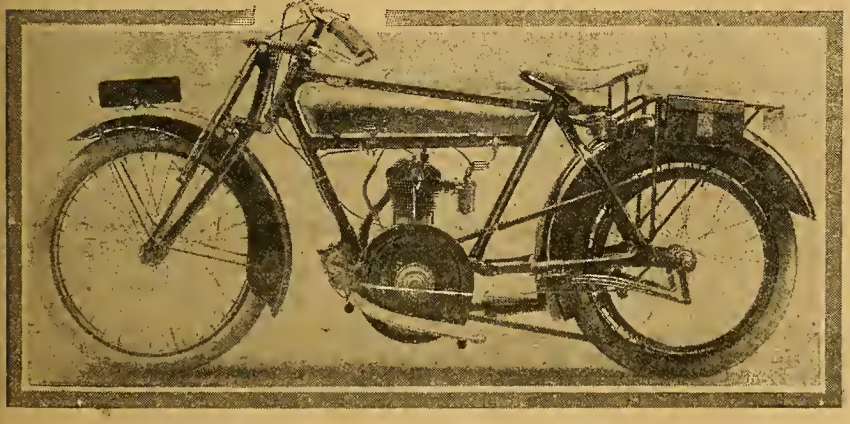


Flywheel side of the Verus Blackburne-engined lightweight.

Another new model is a 2¾ h.p. two-stroke fitted with a Union engine and single geared. Like its larger sister, it is fitted with the Coulson spring frame, and is provided with a double silencer, a large expansion chamber being located below the crank case and a cone-shaped expansion chamber at the end of the exhaust pipe.

The Coulson B, fitted with the 2¾ h.p. Blackburne engine and Albion two-speed gear, has undergone one or two improvements for 1920. Instead of fitting a belt rim brake, a neat type of band brake is now supplied, which is controlled by means of a pedal on the offside of the footboard.

Yet another innovation is the Coulson stand. When jacked up, the top of the stand rests on the bottom bracket, and, owing to its position, the machine is perfectly balanced on it, so that it may be used to raise up either the front or back wheel. Normally, when on the stand, the front wheel remains on the ground, but only the slightest effort is required to raise it, thus allowing the front wheel to be taken out without difficulty. When this has been removed the rear wheel will remain on the ground, owing to the absence of the weight of the front wheel. To place the machine on the ground the back portion is lifted and slightly moved forward, the stand is then pulled up clear by means of a spring, and is finally secured by a clip attached to the top of the crank case.



The 4 h.p. Blackburne-engined single-geared Coulson B. sporting model.

All models of Coulsons to which we have referred are fitted with Capac carburetters, which give eminently good results on these motor cycles.

Stand **SILVA SCOOTER.**

17. Although offered to the public with a seat as an optional fitment, the Silva scooter has been designed primarily as a machine of the "stand-up" type. It is a neat little machine, having a 20in. diameter front wheel, fitted with a 1¾in. tyre, and a 12in. rear wheel shod with a 300×60 tyre. The power unit, in fact the whole of the front wheel, is reminiscent of the Auto-wheel, carried in front forks of the conventional bicycle type.

Of the four-stroke type, the engine has a bore and stroke of 52½ and 54 mm. respectively, and has an automatic inlet valve. The transmission is by chain direct from the camshaft to the wheel.

The frame construction is simple, and includes a rubber-faced platform, which is mounted on springs. A single rod stand is used to hold the machine upright when not in use.

Stand **VERUS.**

17a. Manufactured by a large firm of Midland engineers who hitherto have not been directly in the motor cycle industry, Verus motor cycles bid fair to take a prominent place in the world of wheels next year, and the models to be exhibited at Olympia will show their all-round good quality. These machines do not depart from the conventional, but are good examples of clean design and high-class finish.

Four models will be exhibited, including a new 2¼ h.p. two-stroke with an engine 62×70 mm., Brampton forks, Amac carburetter, E.I.C. magneto, and 24×2in. Dunlop tyres, catalogued at £50. A second two-stroke machine has a 70×70 mm. two-stroke engine (manufactured by the firm as is the smaller engine), Burman two-speed gear, clutch and kick-starter, and 26×2½in. tyres. This type will sell at £75.

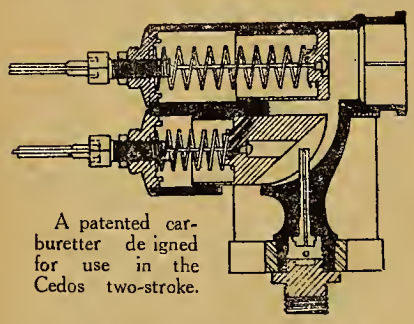
The Verus new four-stroke engine will not have a place in the exhibit, as its manufacture is held up indefinitely, owing to a disastrous fire which destroyed the whole works in which it was being produced, so for the coming year the makers will fit Blackburne engines to the two other models, a 350 c.c. machine selling at £95 and a 4 h.p. dual purpose mount at £105.

Forecast and Guide to the Olympia.—

Stand **CEDOS.**

18. Yet another new firm in the motor cycle industry is responsible for the Cedos two-stroke lightweight—one of the cleanest designed machines which has appeared on the British market. It was fully described in *The Motor Cycle* for October 9th, and the details revealed one of the most carefully thought out lightweights that we have been privileged to examine. One of its chief features is that there are no loose clips or fittings of any description, every detail being so designed that it is brazed or welded directly to the particular part of the frame to which it belongs.

The engine is of the three-port type, having a bore and stroke of 62 and 70 mm. respectively, and a flywheel of comparatively small diameter. The gear box is enclosed in a circular case which, in turn, is fitted in to a circular lug forming the bottom bracket of the frame. While not departing drastically from conventional design, the machine has several distinctive features. Among these may be mentioned the rear guard, undershield, and footboard in one piece; a handsome large capacity tank, embodying a metal tool box in the top; a parallel link type of spring fork, with a single coil spring; and the two brakes on the rear wheel. An open frame ladies' model also will be staged.



A patented carburetter designed for use in the Cedos two-stroke.

Stand **VELOCETTE.**

19. A newly redesigned two-stroke of the smaller class which performed very creditably in the recent Six Days Trials, is the 1920 Velocette, which promises to enhance the already high reputation its predecessors have created in the world of lightweights.

Of a slightly more ambitious type than the conventional three-port pattern two-stroke, the Velocette engine embodies an ingenious system of mechanical lubrication, in the form of a vertical pump, which, operated by a worm gear, has a variable stroke. The crank case is of unique construction, the single web crank being accessible by removing a large circular plate, which practically forms one side of the crank case. The magneto is mounted at an angle on the crank case behind the cylinder. The capacity of the engine is 275 c.c., the bore and stroke being 67 and 78 mm. respectively. Very narrow piston rings are used.

With a sloping top tube, duplex front tubes, black finished tank and gold lines, the whole machine presents a very neat appearance, besides having several little features distinctly its own. We refer to such things as the internal expanding brake—a rarity on small lightweights—the provision made for lubricating the head through a screw cap at the top of the steering tube, and the spring-up rear stand.

Stand **U.S. EXCELSIOR AND HENDERSON.**

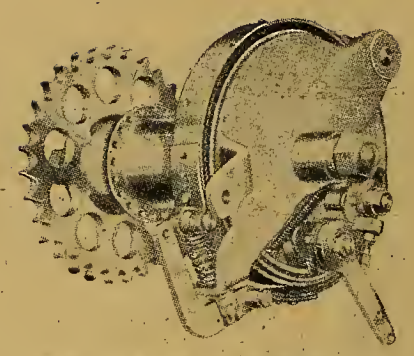
21. Two well-known American machines will be shown on this stand—the twin Excelsior and the four-cylinder Henderson—both of which are coming into favour for sidecar use. Both makes will be exhibited completely equipped with electrical installation, and, in addition, standard models will be shown fitted to sidecars of various types.

Perhaps the greatest interest will be shown in the Henderson machine, if only on account of its four-cylinder engine and combined gear unit. Probably this machine will share with the F.N. the distinction of being types in which most motor cyclists and manufacturers are interested, as the ultimate development of the sidecar *de luxe* machine. Its details are good, and, for a big machine, the outlines are most pleasing.

The cylinders are 70×76 mm., the total capacity being 1,168 c.c., and a four-throw crankshaft is used in conjunction with three large phosphor bronze bearings. The inlet valves are overhead with the exhausts immediately below them, both operated from the same camshaft alongside the cylinders.

Stand **IXION.**

22. A full range of the 1920 Ixion two-strokes will be exhibited by the Ixion Motor Manufacturing Co., who for several years have specialised on the lightweight machine both for solo and light sidecar work. The main models will be of 2½ h.p. with single and two-speed gears; an entirely new model will also be shown which is fitted with a 350 c.c. Precision two-stroke engine. This machine, fitted with a Sturmey-Archer gear box, will be marketed as a sidecarette with a light, quickly detachable sidecar of the firm's own design. An illustration of this machine appeared in the last issue.



The contracting band expanding ring brake on the American Excelsior.

Stand **A.B.C.**

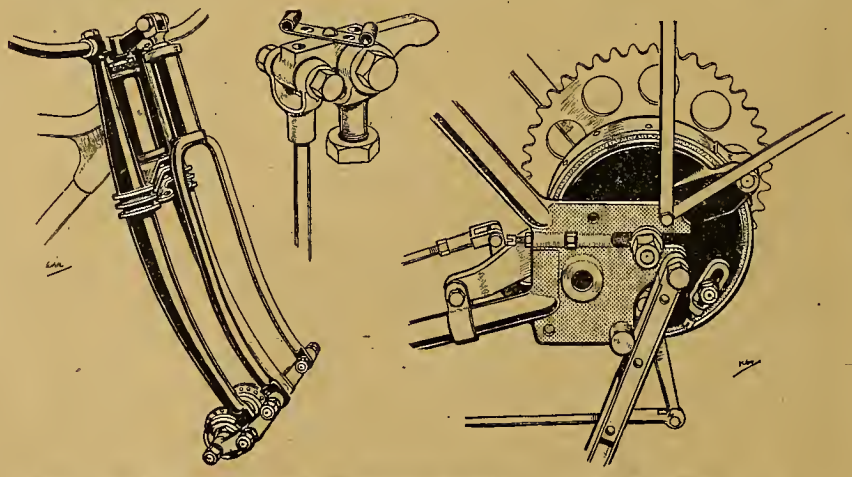
23. As may be imagined, the alterations in the production model A.B.C. are only in detail, and we understand that, by the time the Show opens, the Sopwith Co. will be in a position to deliver a certain quantity of these machines to their agents.

So far as the engine is concerned, which, we may remind our readers, has a bore and stroke respectively of 69×54 mm. (400 c.c.), the chief alterations have been the fitting of larger diameter tappet rods and of altering the design of the tappet adjusters. The tappet adjusters now consist of hardened steel screws with hollow cone ends screwing into the tappet heads themselves and secured by lock nuts.

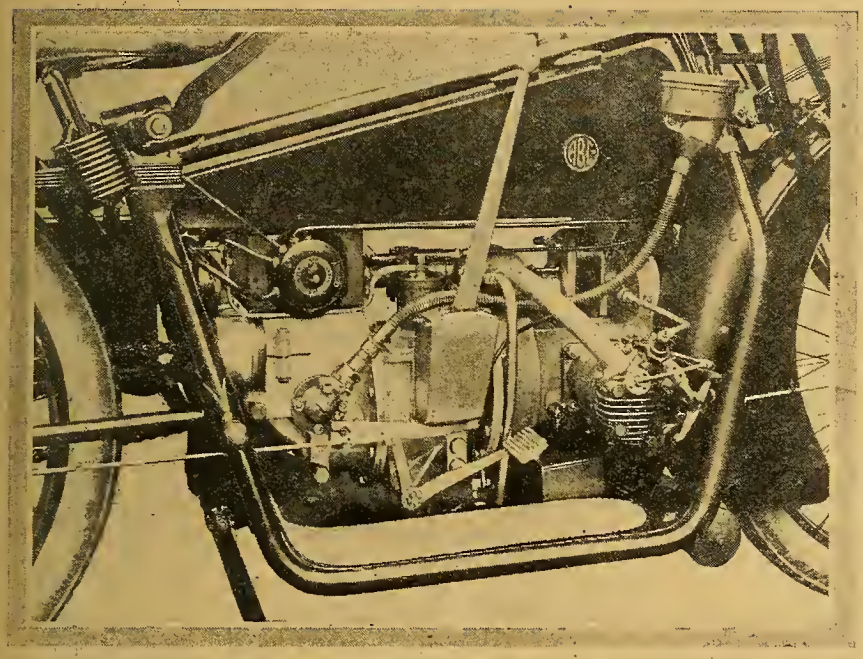
Tapered coil springs are now used for the valves instead of the volute variety which were fitted to the experimental model.

The lubrication has been considerably simplified, as the mechanical oil pump has been abandoned, and, instead, oil is fed from an automatic adjustable sight feed mounted on the tank, the oil being induced by suction from the crank case. In addition, an auxiliary hand-pump is also provided.

An innovation has been introduced in the shape of adopting the single-lever



Some details of the new model four-cylinder Henderson which will be exhibited on Stand 21. (Left) The front forks, showing the triple plate construction of the main fork crown. (Centre) Pivoted spring clip for protection of oil holes in bearings of overhead inlet rockers. (Right) Details of expanding and external rear brakes and position of sidecar connection.



The enclosed gate change, Lucas switchboard, and the enclosed speedometer drive of the A.B.C.

Claudel-Hobson carburetter which is coupled up to an exhaust heated induction pipe.

The 1920 models are equipped with a rear stand so placed that the machine can be jacked up with one hand, and a front stand is also fitted.

Improvements have been made to the clutch by the addition of a very strong central spring, and four auxiliary springs placed at equal intervals round the clutch face.

Throughout the whole design, parts have been strengthened and improved in detail. One point we may mention is the fixing of the chain sprocket to the transverse gearshaft. The sprocket has a threaded boss and is keyed on to the shaft, the end of which is also threaded. A large nut is threaded on to the boss, and inside it is a flanged castellated nut screwed on to the shaft. Both are screwed on together and locked up tightly. When it is desired to withdraw the sprocket, the large nut is loosened and then the castellated flanged nut, and, if the latter is unscrewed, the sprocket is drawn off. This overcomes the difficulty which is often encountered by many motor cyclists who wish to dismantle their chain sprockets, since with this simple self-contained device no special tool such as is ordinarily used for this operation is necessary for the purpose.

It is interesting to note that the following gear ratios have been adopted for the solo A.B.C.: top 5.5 to 1, third 7.31 to 1, second 9.75 to 1, first 13.16 to 1, while the top gear ratio for sidecar outfits is 6 to 1.

A special housing cast on the top of the bevel casing accommodates a Lucas dynamo, which is driven by a spur wheel from the mainshaft in the gear box. A switchbox is carried on a metal case fixed on the top of the dynamo housing, while the accumulator is accommodated on the left-hand side of the frame behind the saddle tube. A Smith speedometer is also fitted.

The finish is particularly good, a gunmetal effect being obtained by a special process, which includes stove enamelling. There are very few plated parts, and parts which are plated are heavily coppered before they receive the deposit of nickel.

Five-point connection is used to fix the sidecar to the motor bicycle, the sidecar axle being attached to the rear chain stay by means of a spherical joint. The springing of the sidecar has been carefully thought out; quarter-elliptic laminated springs serve to suspend the axle in harmony with the springing of the motor bicycle, while the quarter-elliptic springs form a continuation of the C springs of the sidecar body.

Stand **WATSONIAN SIDECARS.**

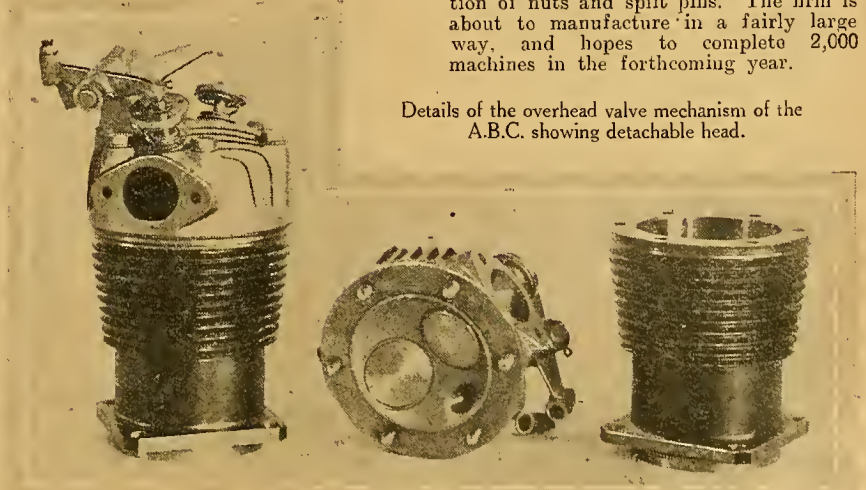
25. Several new and interesting sidecar designs will be exhibited by this well-known sidecar firm, the chief among which will be the "Supreme" and "Zeppelin" models, both of which embody coil spring suspension on a light, but sturdily constructed chassis. The "Zeppelin" is a particularly good-looking body of the sporting type, and is torpedo in shape. Behind the seat there is a roomy compartment for the accommodation of petrol and luggage. While the body is of the type designed to reduce head resistance to a minimum, the passengers' comfort has not been sacrificed to bring this about.

The "Supreme" model is of the touring type, and has an unusually large locker at the rear, in which a petrol can and a suit case can easily be accommodated in addition to small packages.

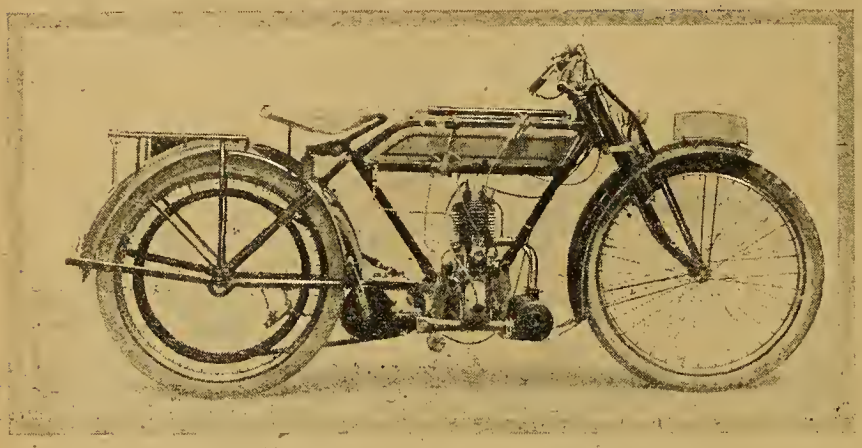
Stand **HOSKISON.**

26. The Hoskison Manufacturing Co., Ltd., are newcomers to the motor cycle world who have caught the trend of modern thought in an admirable manner. The two-stroke lightweight which they will exhibit is described elsewhere in this issue. Fitted with a "Union" engine of 70×76 mm. bore and stroke, the frame is strong, and gives a low riding position. A Brown and Barlow carburetter supplies gas, and the charge is fired by a Runbaken magneto, controlled from the handle-bar. Chain and belt drive is employed, a Burman two-speed gear being used to provide suitable ratios, this gear is fitted with a kick starter and handle-bar controlled clutch. The rider's comfort has been carefully studied, and in addition to Saxon forks Terry spring links are a standard fitting.

Seven-inch valanced guards are used over both wheels, and the specification includes Lycett pan seat, extra large tool bags, and 26×2½in. heavy Kempshall tyres. The tank holds 1¾ gallons of petrol and three pints of oil. The work is very complete, and includes petrol filter, Best and Lloyd sight feed lubrication, and a large aluminium silencer. Special mention is deserved by the very complete kit, which contains, in addition to all necessary tools, a sparking plug, chain links, belt fasteners, tyre repair outfit, and a selection of nuts and split pins. The firm is about to manufacture in a fairly large way, and hopes to complete 2,000 machines in the forthcoming year.



Details of the overhead valve mechanism of the A.B.C. showing detachable head.



A newcomer in the motor cycle world—the Hoskison two-stroke.

The attractive appearance of the machine, which is finished in black with French grey tank lined in black and gold, should help to dispose of the output of this workmanlike little mount.

Stand **JOHNSON MOTOR WHEEL. AUTOPED SCOOTER.**

28. Elsewhere in this issue will be found a detailed description of the auxiliary attachment known as the Johnson motor wheel, which will be exhibited on this stand. Its especial interest lies in the engine, which is of the flat twin two-stroke type embodying a combined lighting and ignition unit in the flywheel.

On this stand also will be shown the American Autoped scooter, which was one of the first machines of this type to be introduced into this country. It has a small four-stroke engine with a flywheel type magneto, which also supplies current for lighting.

Stand **STANGER.**

28a. The exhibit on this stand is a V twin two-stroke engine, particulars of which will be found elsewhere in this issue.

Stand **GRINDLAY SIDECARS.**

30. A new sidecar, introduced in 1919—the Grindlay—is already popular on almost every type of machine. It has several features exclusively its own, not the least among them being the spring wheel, which is suspended on two semi-elliptic springs, and the cantilever springing of the body. In subsequent issues, we shall deal more fully with this and other sidecars.

Also exhibited will be the new Grindlay sidecar screen, which has an adjustable fixing of an ingenious character.

Stand **A.J.S.**

31. A.J.S. motor cycles and sidecar outfits have earned such a reputation for reliability and quiet running that there is no need for us to go into details of these well-known machines. It is sufficient to state that the firm will exhibit their well-known 6 h.p. sidecar combination, which has a twin-cylinder engine of 74×87 mm. bore and stroke.

Two new features to be fitted on future models are a spring saddle pillar and the lever stand—a device which enables the machine to be raised on to its stand with the minimum exertion.

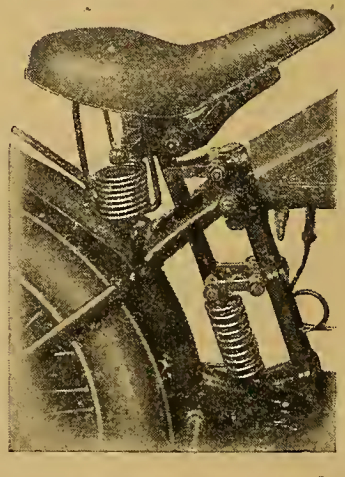
For the benefit of such as have only recently become interested in motor cycle matters, it should be stated that the all-chain transmission is very thoroughly enclosed, and that a three-speed gear box is carried behind the engine; an excellent clutch and kick-starter are employed, and the cylinders have easily detachable combustion heads. 700×80 mm. tyres are fitted to detachable and interchangeable wheels, and the finish is in black relieved by a broad gold line on the tank. A frame, built entirely of straight tubes, is one of the features of modern A.J.S. motor cycles, the top tube being covered by the duplex tank—a form of construction which considerably simplifies cleaning.

The sidecar is fully equipped with screen and sprung luggage carrier, and is finished in black to match the machine.

Stand **CORONA JUNIOR.**

32. Despite the trend of design, which leads to a more general adoption of multi-cylinder engines and the two-stroke principle, interest and experiment in the 500 c.c. class of four-stroke single are by no means on the wane.

A newcomer to the Show is the Corona Junior, manufactured by the Meteor Manufacturing Co., Ltd., and this machine is equipped with a long-stroke outside flywheel engine of very attractive pattern. Elimination of redundant parts has been consistently aimed at by the designer of the power unit, the idea being to attain simplicity of construction and reliability in running. Mechanical pump lubrication is adopted.

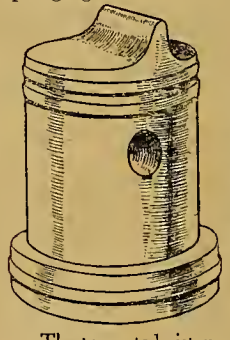


A spring seat-pillar on the 1920 A.J.S. model, now a standard feature.

The cycle parts have all been designed with an eye to the practical rider's requirements, and all types of users will be catered for in a range which includes fixed gear and light two-speed solo models and a heavier mount with three speeds, suitable for passenger work.

Stand **DUNELT.**

33. A large air-cooled two-stroke is a novelty which is bound to attract attention. Not long ago the achievement of such an engine would have been deemed unlikely, but so great has been the advance in knowledge with regard to cooling in recent years that Messrs. Dunford and Elliot are proposing to exhibit their 500 c.c. single-cylinder two-stroke, which has performed so satisfactorily on test. The Dunelt motor cycle was described in *The Motor Cycle* of November 6th, and our readers will remember that one of the most interesting features of the engine is its truncated piston, by means of which better scavenging and a full charge are procured. A two-speed expanding clutch gear is fitted in the countershaft, the final drive being by belt. Several features of interest present themselves to a student of design, notably the leaf springing of the front fork, the interchangeable wheels, and the loop frame, with two sloping tank tubes.

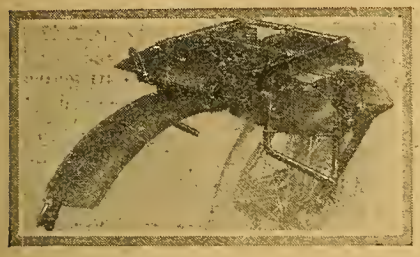


The truncated piston of the 4 h.p. two-stroke Dunelt.

Not the least attractive feature is the selling price, which, it is hoped, will be in the region of £70. This, taken in conjunction with the fact that the machine will pull a sidecar satisfactorily—it has, in fact, been designed with this end in view—is a surprising figure, and will do much to attract public attention.

Stand **ABINGDON.**

34. In addition to the several popular Abingdon King Dick models known to most of our readers, *i.e.*, the 3½ h.p. T.T. solo machine, 3½ h.p. countershaft model, and the three-speed chain-cum-belt 6 h.p. twin, a new King Dick will be shown at Olympia, which embodies several important features. This machine is fitted with the King Dick twin engine, which has a bore and stroke of 73 and 95 mm., and has 28×3in. detachable and interchangeable wheels with round base rims. The rear brake is of the internal expanding type, the transmission all-chain, and a Lucas Magdyno combined ignition and lighting set, which, with the Canoelet sidecar, will make it a *de luxe* model in every way.



The lift-up rear mudguard of the Abingdon, showing semi-concealed valises.

Stand **BAMCO SIDECARS.**

35. A sidecar chassis with all joints welded instead of embodying brazed lugs, and also having a spring wheel, is the speciality of the Birch Manufacturing Co., who are exhibiting their models at this stand. The sidecar was dealt with at length in our issue for October 23rd.

The chief feature of the design is the unique method of springing the wheel, which is contained in a rectangular frame, the rear end of which is pivoted to the rear cross-member of the chassis. At the forward end the wheel frame is attached to the chassis by two links, with two coil springs to control its movement.

Stand **SIMPLEX AUXILIARY ATTACHMENT.**

36. The Simplex auxiliary motor attachment for pedal cycles is not a new proposition, but so far it has not been manufactured in the quantities which its makers are preparing to market next year. The 1920 model is practically the same as the 1919 type for the very good reason that the latter has been the sample models of the former.

An extremely neat and well-designed two-stroke engine of 1 h.p. is fitted horizontally in an aluminium base, which forms a carrier for the bicycle. In this is also located the countershaft clutch, magneto, and petrol tank. The whole outfit is self-contained except for the large chain wheel, which is fitted on the wheel of any ordinary bicycle, and the controls carried on the handle-bar.

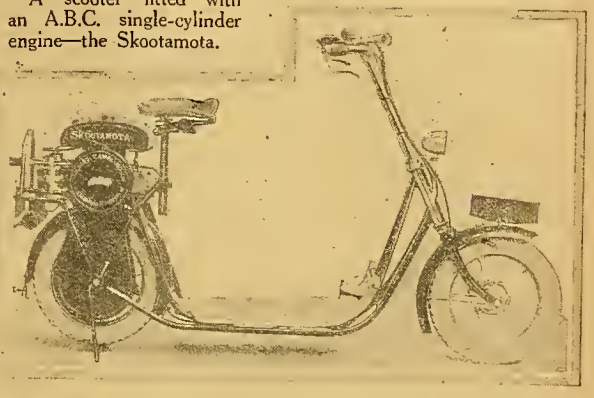
Stand **CASTLE THREE-WHEELER.**

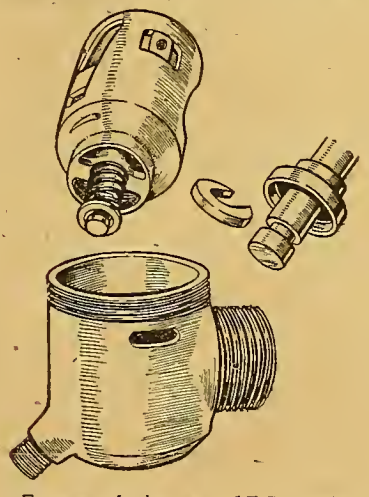
37. A light car in all but the number of wheels, the Castle three-wheeler is interesting as a type which embodies everything usually found in a conventional four-wheeler, excepting the rear axle and two rear wheels. Its specification includes four-cylinder water-cooled engine, shaft drive, and artillery wheels.

Stand **L.S.D. RUN-ABOUT.**

38. Another three-wheeler is the L.S.D., which follows the conventional practice of the runabout type. This machine includes an air-cooled J.A.P. engine, and shaft and chain transmission, with a two-speed and reverse gear box. Quarter-elliptic springs are used at the rear, and a patented system of springing by enclosed coiled springs at the front. 700×80 mm. tyres, on Sankey steel wheels, form part of the equipment of the machine, which has a wheelbase of 6ft. 6in. and a track of 4ft.

A scooter fitted with an A.B.C. single-cylinder engine—the Skootamota.





Features of the new J.E.S. auxiliary motor—the floatless carburetter and the valve fixing.

Stand **J.E.S. AUXILIARY ENGINE.**

39. By no means the least interesting of the auxiliary motors which will be offered to the public at Olympia will be the J.E.S. It is, in fact, one of the best designed engines we have examined, and embodies a mechanical oiling system by a pump submerged in the oil sump.

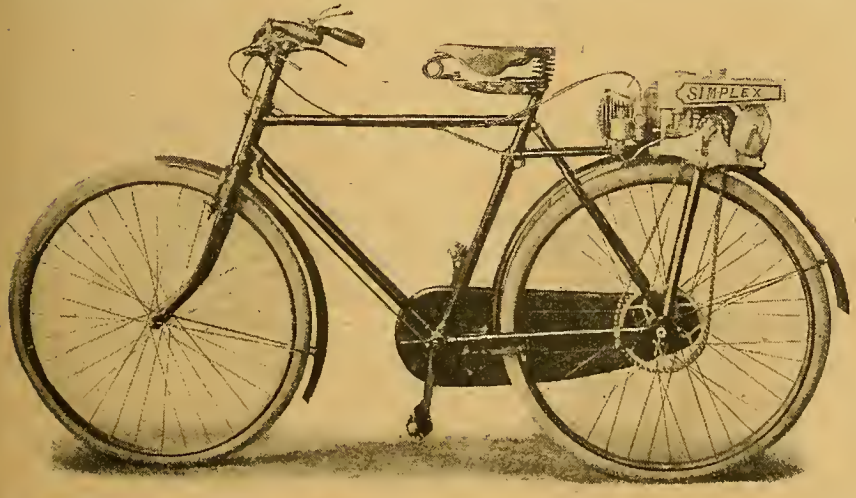
Before the war the J.E.S. had built for its manufacturers a good reputation among riders of auxiliary attachments, but the 1920 model has many improvements and innovations which the fully fledged motor cyclist will wish were embodied in larger engines.

Both valves are now mechanically-operated, and the carburetter fitted is of a new patented type having no float. It is a single-lever instrument.

The bore and stroke are $2\frac{3}{16}$in. (55.5 mm.) and $2\frac{3}{8}$in. (60.3 mm.) respectively, and an aluminium piston is used which has a floating gudgeon pin.

In addition to the auxiliary motor, on this stand will be exhibited the J.E.S. ultra-lightweight, which is engined with the power unit referred to, and is fitted with a specially designed diamond frame, and spring forks.

The price of the lightweight is 36 gns.—for the motor attachment, 20 gns.

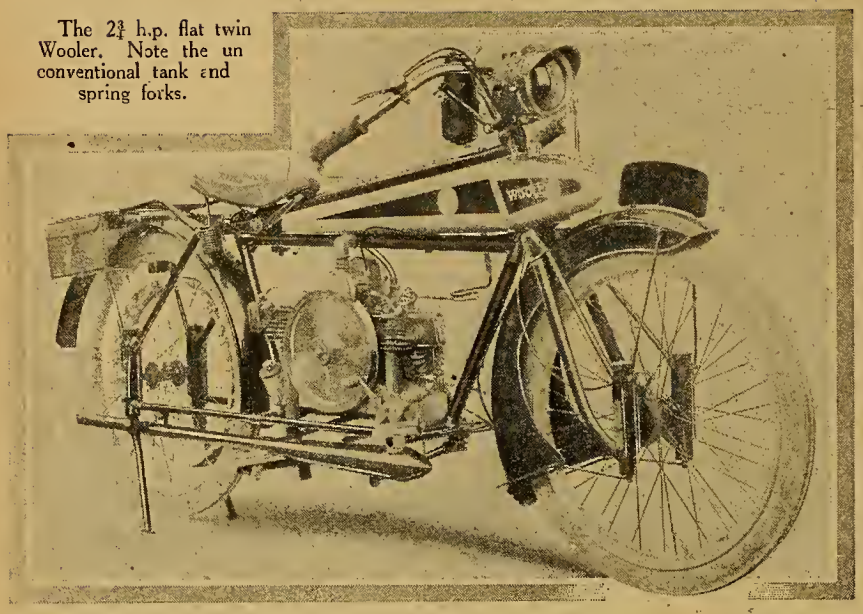


A motorised bicycle. The compact power unit on the carrier is the Simplex

Stand **SKOOTAMOTA.**

41. There is no gainsaying the fact that the A.B.C. Skootamota has created a tremendous amount of interest on the part of the general public, and Messrs. Gilbert Campling's exhibit of these interesting miniature motor cycles no doubt will attract its full share of attention. In addition to the standard models, two new machines, intended for commercial purposes, will be exhibited. On these large boxes for parcels are fitted, and form the support for the spring seat for the operator. There will also be a "tropical" model, finished in light colours and complete with a canopy which will appeal to those who live in a climate where such equipment is necessary, while for those Eastern potentates who, years ago, used nickel-plated bicycles, a standard model will also be shown finished in this way.

It will be recalled that the Skootamota is to all intents and purposes a miniature motor cycle fitted with an



The 2¾ h.p. flat twin Wooler. Note the unconventional tank and spring forks.

open frame and pan seat saddle. The engine is a 1½ h.p. four-stroke, placed horizontally over the rear wheel, which it drives by means of an enclosed chain. 16in. diameter wheels are used with 2¾in. tyres. The equipment embraces horn, pump, tools, and, for 49 gns., the price includes the registration fee.

Stand **BLACK PRINCE.**

42. If only because it is one of the most unconventional machines yet produced as a serious proposition to be offered to the public, the Black Prince will create a large amount of interest at Olympia next week. In several ways its construction is a considerable advance on present practice, and in the opinion of many, is a representative of a system which designers will more carefully study in the near future.

Pressed steel is used practically throughout the construction of the frame, which is sprung at the rear on volute springs. Apart from the manufacturing conveniences which such construction is said to possess, the Black Prince design entirely encloses the mechanical elements of the machine, and, in addition, provides protection for the rider against mud thrown off the front wheel.

The engine of one model is particularly interesting, and is of the flat twin two-stroke type, having a cast member connecting the two combustion heads. By this means a single plug only is necessary simultaneously to fire both charges, and as the new gas enters the cylinders by way of this common combustion head, the spark takes place in gas which must be entirely unpolluted by burnt gases. Altogether the Black Prince is a remarkable machine, and probably will be one of the most discussed models in the Show.

Stand **MARTINSYDE.**

43. Made by an aviation concern known to all who followed the evolution of the aeroplane during the war, the Martinsyde motor cycle is another newcomer to the industry, and this time a passenger machine of more than ordinary interest. Of 6 h.p., the machine has been designed by Mr. H. C. Newman, the Ivy-Precision exponent, and has a twin-cylinder engine with a bore and stroke of 70 and 88 mm. (678 c.c. capacity). The exhaust valves are overhead, and the inlets at the side.

Roller bearings are used at the big ends, and large size ball bearings support the crankshaft. Lubrication is by an automatic system embodying a sump in the timing case.

The three-speed gear box is of the A.J.S. design, made under licence, and the all-chain transmission is enclosed in oil-retaining cases.

The machine generally follows conventional practice and embodies a Brampton Biflex spring fork, large capacity tank, and 650×65 mm. wheels, while the finish will be in the now popular black and gold.

A specially designed sidecar with a large locker at the rear and fitted with an Auster patent windscreen will be sold with the machine, which will be known as the Martinsyde-Newman. It is stated that deliveries will commence in January.

Stand **OMEGA.**

46. Omega motor cycles, during 1919, have considerably enhanced the pre-war reputation of their makers by their sturdy construction and general appearance, and, while not differing to a large extent, the 1920 machines have been improved in details. A new model will be introduced which, like its predecessors, will be fitted with the well-known J.A.P. 2¾ h.p. engine, but will have a gear box with clutch and kick-starter.

Various types of these machines are made, including semi-T.T. and touring models, the former differing from the general specification in several details, such as the substitution of footrests for footboards and the adoption of low, wide handle-bars.

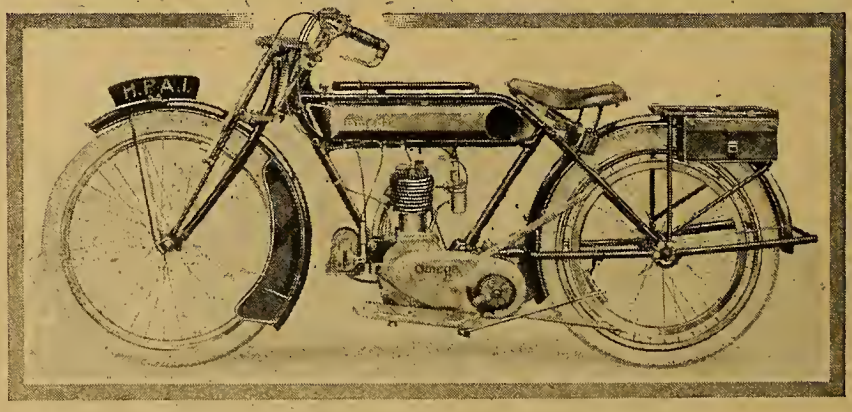
Stand **WOOLER.**

47. As one of the new post-war flat twins of 2¾ h.p., the new Wooler has several features not at all usual in a machine of its type. The peculiar tank, with its forward extension beyond the steering head, and the system of springing both wheels are all points which render the machine distinctive, but probably the most interesting item in its specification is the variable gear and long belt drive.

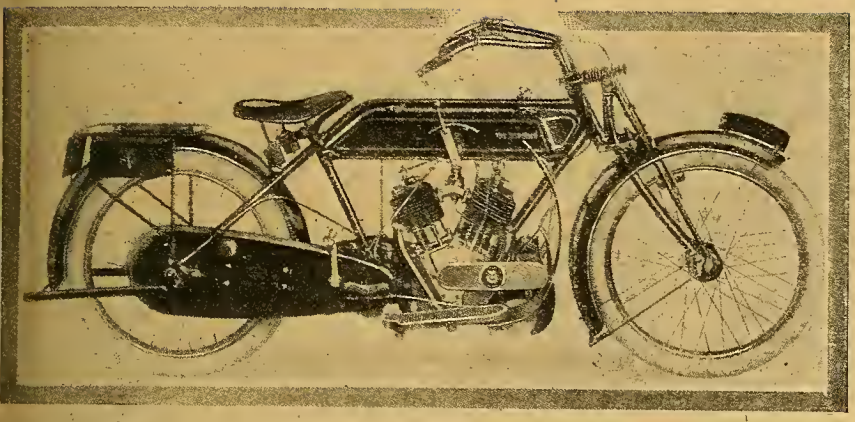
This gear is a modification of that fitted to the pre-war two-stroke model, and consists of a variable pulley which, in expanding or contracting, maintains a constant tension on the belt. The engine, too, is unusual, and has overhead inlet valves with automatically lubricated rocker arms. The cylinder heads are detachable, and mechanical lubrication by a chain elevator is embodied.

Stand **MATCHLESS.**

48. The 1920 Matchless needs no introduction to the majority of readers of *The Motor Cycle*, for during the past year it has undergone strenuous road tests in view of the public. It is a spring frame model, in which coil springs are used throughout, and the movement of the sidecar wheel is made to synchronise with that of the driving wheel. The engine fitted is an 8 h.p. twin J.A.P., driving a three-speed gear box of Matchless manufacture, which is fitted close up to the engine, from which it is driven by silent chain. The wheels are 28×3in., and are interchangeable, a spare being carried on the sidecar. Stands are fitted to all wheels, and the



A 1920 Omega model, engined with a J.A.P. power unit of 2¾ h.p.



The 8 h.p. Sunbeam, primarily designed for sidecar use. The engine is 85.5 × 85 mm. = 976 c.c.

equipment throughout is of the most complete character. The price of the standard model is £170, with windscreen and grid, while at £200 the machine is catalogued equipped with Lucas Magdyno, lamps, horn, hood, and pillion seat.

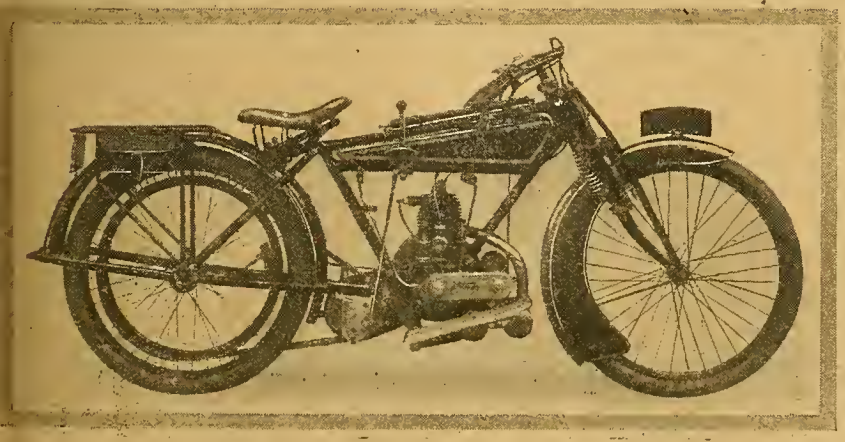
Stand **SUNBEAM.**

49. The 8 h.p. Sunbeam which will be exhibited will differ very little from the model which has been produced during 1919. As before, the striking black and gold finish will be standard, and the well-known Sunbeam oil bath part of the equipment. Unlike many similar motor cycles, the chain case of the final transmission is on the right side of the machine. The J.A.P. 8 h.p. engine will be retained.

Chief among the modifications of the 3½ h.p. model will be the new Sunbeam spring fork, which has been undergoing exhaustive tests during the past twelve months. This embodies a single leaf spring extending forward, and is quite pleasing to the eye. Another feature will be that, for 1920, this model will be marketed as a passenger machine, with a sidecar of Sunbeam design, and having a chassis of unique construction. Detachable wheels will be fitted, and no doubt the 3½ h.p. Sunbeam sidecar outfit will take a leading place among single-cylinder passenger machines as it has among solo mounts.

Stand **LEA-FRANCIS.**

50. Before the war, there were several twin solo machines of 3½ h.p. and under, but few have been re-introduced. The 3½ h.p. twin Lea-Francis was always regarded as a solo machine *de luxe*, and, although the makers announce that their 1920 output is booked up, the exhibition of this machine will be appreciated by all who take an interest in the high-class motor cycle. The Lea-Francis set the fashion in more than one direction, including V rim brakes on the front wheel. A J.A.P. engine having a bore and stroke of 70 mm. and 64.5 mm. (494 c.c.) respectively is fitted, with the magneto snugly placed at the rear; the gear box is of the two-speed type, and the all-chain transmission is entirely enclosed. Quickly detachable wheels are fitted. An alternative model will be marketed, which will be fitted with a M.A.G. engine.



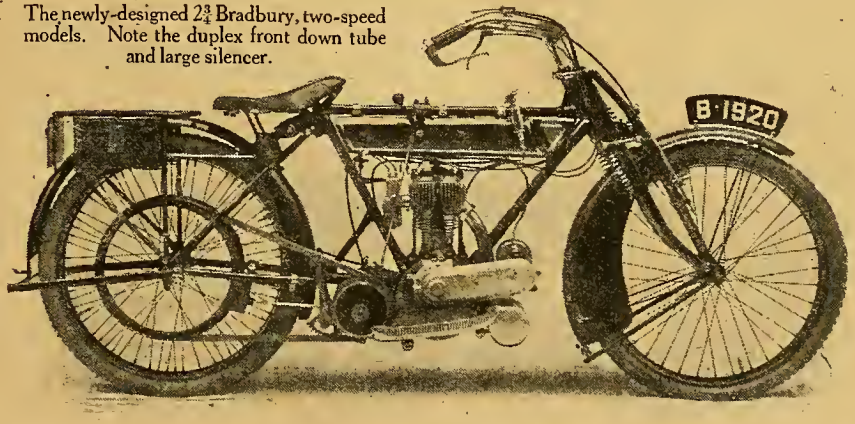
One of the Excelsior range for 1920, the 2¼ h.p. two-stroke model.

Stand **BRITISH EXCELSIOR.**

51. With the 1920 models, Messrs. Bayliss, Thomas Co., the proprietors of the Excelsior Motor Co., enter upon what promises to be a period of largely increased outputs, as their recent move to a larger factory in Birmingham now places the concern in a very much more favourable position than hitherto has been the case. The models which they will exhibit at Olympia all reveal the beneficial results of the increased manufacturing facilities, and will no doubt meet with favour from buyers of lightweights and heavy sidecar machines.

The five new models include four lightweights which have frames with sloping top tubes. The first is fitted with a Villiers engine, countershaft two-speed gear, 26in. × 2¼in. tyres, Druid forks, Amac carburetter, and pan saddle, and is catalogued at £58 16s. An alternative model is fitted with a two-speed gear having a clutch and kick-starter at £64 17s. 6d.

The newly-designed 2¾ Bradbury, two-speed models. Note the duplex front down tube and large silencer.



In the passenger machine class, the 8 h.p. Excelsior is also a new model with many points to interest the buyer of a big twin sidecar. It has 28 × 3in. wheels, detachable and interchangeable wheels, all-chain drive entirely enclosed, internal expanding rear brake, and large capacity tank.

The sidecar is exceptionally roomy, and is carried on an underslung chassis with the luggage grid sprung with the body. Provision is made for carrying a spare wheel on the sidecar. The price of this machine with 6 or 8 h.p. engine is £162 10s.; spare wheel and tyre £8, Lucas dynamo lighting set with electric horn £25.

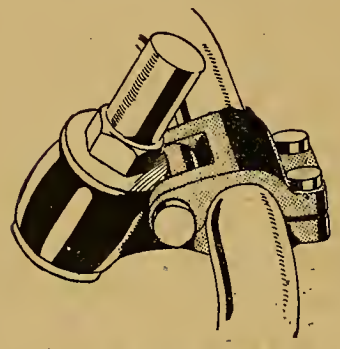
Stand **BRADBURY.**

52. This exhibit will without doubt attract many of those who are interested in the light single-cylinder, since a new 2¾ h.p. model is to be staged. The

Forecast and Guide to the Olympia.—

Bradbury firm is therefore one of the few large firms at present making a motor cycle of this type throughout as distinct from those which are assembled from proprietary units.

Following the practice adopted many years ago, the crank case is incorporated in the frame, the main tubes being brazed into it. A detachable cylinder head is fitted, and a two-speed gear,



How the Rex adjustable handle-bar is secured.

with the clutch rather unusually placed in the final driving pulley, is employed in conjunction with chain and belt transmission.

Other Bradbury models are the well-known "square" engine 4 h.p. single, with all-chain drive, three speeds and handle-bar controlled clutch, and the 6 h.p. twin, with detachable head cylinders, chain transmission, and a similar gear box to that on the 4 h.p. single-cylinder machine. The clutch control on the twin is operated by either pedal or handle-bar lever.

Duplex front frame tubes are being adopted on the Bradbury models, and sidecar lugs are incorporated in the big twin. Grindlay sidecars are fitted as standard.

Stand **MILLFORD SIDECARS.**

53. Owing to difficulties of manufacture the range of Millford sidecars will not be so extensive as at previous shows. The Millford "Corvette" will be shown, however, together with a new "De Luxe" model, which will be found very suitable for use with the high-powered motor cycles now being manufactured. Possibly the feature which will appeal most will be the extremely neat luggage carrier with which the body is fitted. When required the back of the body falls down to a parallel position, being supported on either side by strong straps, capable of carrying a good-sized portmanteau. This back, when not in use, folds into the body itself, and is therefore concealed in the neatest manner possible.

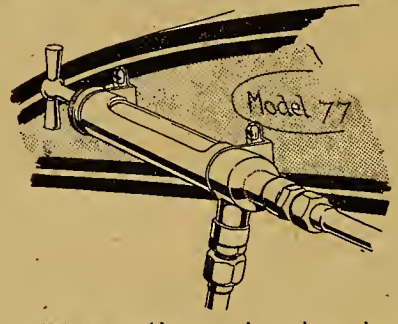
Users of lightweights are catered for in the "Skiff" model; whilst the family man's wants are also anticipated in the Millford "Family" car. This has an extra long body, and is fitted with a small seat in the front portion for a child. An efficient and neat screen of the firm's own manufacture is placed immediately in front of the little seat so as to offer the fullest protection for both passengers.

Stand **F.N.**

54. The F.N. exhibit will consist of four four-cylinder motor bicycles and four lightweights, both models following the 1914 lines with slight improvements. An additional girder now extends from the fork crown to the top of the head, and a slight alteration has been made to the lubrication system, oil to the tank running straight through to the pump.

To the 1920 model an Amac carburetter will be fitted and a Fellows magneto. The 2½ h.p. remains unaltered, except that an Amac carburetter replaces the F.N.

It will be remembered that when hostilities broke out the firm were just beginning to deliver the new 7 h.p. four-cylinder, a thoroughly up-to-date motor cycle, fitted with three-speed gear and mechanical inlet valves to the engine. It is really wonderful that the firm is able to exhibit motor bicycles at all, when it is borne in mind how severely the Herstal factory suffered during the



A large outside pump is used on the Rex sidecar single in addition to the mechanical lubricating device.

war. The Germans destroyed the laboratory, and out of 4,000 machine tools only 300 were left behind, while out of 4,000 workmen only 1,500 can now be employed. Fortunately, a number of partly machined parts were left, and with these the firm has been able to make up a certain number of machines.

Stand **REX.**

55. Manufacturing difficulties have held up the production of the Peace model Rex single, or it would have figured more prominently on the market during the present year. Designed essentially as a sidecar machine, it is characterised by its exceptionally large frame and long wheelbase—points in its favour for passenger work. The engine, too, departs from the general run of single-cylinder power units, having a mechanical oiling system. The bore and stroke are 84 and 98 mm. respectively, the capacity being 543 c.c.

28×2½in. tyres are fitted on detachable and interchangeable wheels, and a spare wheel is carried at the rear of the sidecar body. The transmission is by chain and belt through a Sturmey-Archer gear box.

Stand **SUN.**

57. One model only will be marketed and shown by the Sun Cycle and Fittings Co., and this will be a neat little machine of very distinctive design, embodying many features of interest. The two-stroke engine is placed in the loop frame in a position inclining forward, and is fixed directly to lugs on the tubes instead of the more usual method of using engine plates, and the magneto inclines to the rear. The power unit thus fits snugly between the two diagonal tubes of the frame.

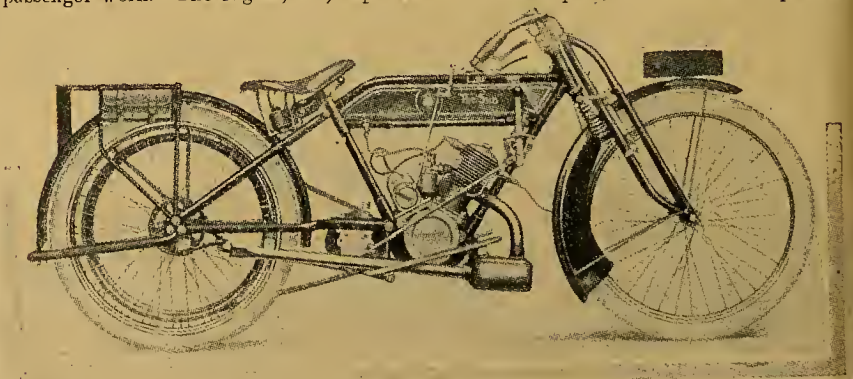
The adjustable tappet on the Ariel, which can be operated without the use of tools

Several noteworthy points are embodied in the engine in which, in the first place, a single web crank is used in conjunction with a long plain bearing to support it. The crank case is a one-piece aluminium casting having a circular cover plate on one side. When this is removed and the cylinder lifted, the shaft, big end, connecting rod, and piston can be dismantled, leaving the crank case in the frame.

Stand **ARIEL.**

59. The Ariel exhibit will include the four models which will be offered for 1920. Two of these are entirely new. The 3½ h.p. single-cylinder and the 6-7 h.p. twin, with combined chain and belt drive, will still be catalogued as solo mounts, or with the Ariel coachbuilt sidecar as a complete combination. A number of improvements have been made in the specifications, including larger and wider mudguards, and new pattern hubs.

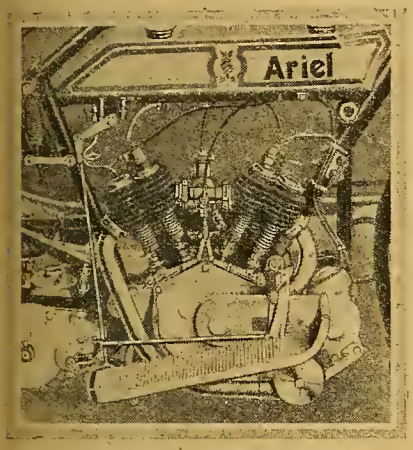
Rated at 4½ h.p., the new single-cylinder Ariel has a bore of 86.4 mm. and stroke of 100 mm., giving a capacity of 586 c.c. Both valves are very large and wide apart, and the valve pockets



The Sun two-stroke, one of the few single-cylinder lightweights with inclined engine.

Forecast and Guide to the Olympia.—

have large air spaces completely surrounding them. Lubrication is by means of suction from a pump, with an improved system of oilways to all the wearing parts. The patent Ariel decompressor is fitted, which ensures easy starting. The power is transmitted from the engine through the Ariel countershaft three-speed gear box to the rear wheel, and the rear transmission is



Power unit of the 6-7 h.p. Ariel.

by chain. The frame is exceptionally strong, having been specially redesigned with a long wheelbase, long head, and duplex front tubes. It gives a low saddle position and 6in. ground clearance, which will be much appreciated by Colonial riders. The front forks are considerably improved, being much wider and stronger. The wheels have Dunlop studded tyres, 28×3in., with flat base rims, and improved hubs are fitted with a special greasing arrangement. The Ariel spring seat-pillar will be retained, and an internal expanding brake will be fitted to the rear wheel, foot-applied, and a band-applied front rim brake. The tank will carry approximately two and a half gallons of petrol and five pints of oil.

The 6-7 h.p. model will combine the aforementioned improvements, and the prices of the four models will be as follow: 3½ h.p. solo £100, sidecar £135; 6-7 h.p. chain-cum-belt solo £120, sidecar £155; 4½ h.p. chain drive solo £115, sidecar £150; and 6-7 h.p. chain drive £130, sidecar £165.

Stand **NEW IMPERIAL.**

60. Two models only will again be the New Imperial programme, and the examples of these machines which will be on view at Olympia will embody only minor improvements. The light tourist model, however, will be obtainable with two-speed gear, or with a two-speed gear combined with clutch and kick-starter. One of the most popular machines in the lightweight class, the New Imperial Jap-engined solo mount, will be fitted with 26×2½in. tyres and a pan seat saddle. The tank has been enlarged, and now holds one and a half gallons of petrol and one quart of oil. A 5½in. rear mudguard is a feature worthy of mention, as is the way in which belt is made to pass through it instead of at the side of a "trapped" out indentation. The upper portion of the passage way has a gutter, which is carried right round to the bottom portion. Therefore mud and water are carried away clear of the belt.

The New Imperial 8 h.p. sidecar is fitted with an 8 h.p. J.A.P. engine, with a capacity of 964 c.c. and 28×3in. Dunlop tyres, and the ground clearance is six inches. Transmission is by two Hans Renold chains. The rear brake is actuated by the right foot from a large adjustable footboard in aluminium. This is effected by a straight rod to the inside of a special pulley attached to the back wheel. The brake block is of Ferodo, and has a large circular bearing surface.

Special attention has been paid to the frame, the two-way webbed head lug being so designed as to take the top tube, middle tube, and the bottom tube in one lug, and thus ample strength is secured at the most vulnerable point of a heavyweight motor cycle frame. The gear box has three speeds. Direct drive is on top, and the main shaft runs in a journal ball bearing, the layshaft running in phosphor bronze bushes. Improvements have recently been made in the shaping of the sliding gear pinions, which add to the silence of an admittedly first-class piece of workmanship. Ample mudguards are provided, together with a shield to the magneto, which also has the effect of protecting the engine and rider from mud and wet. The tank is of large capacity, and has sight feed, and Best and Lloyd pump.

An extremely well sprung sidecar, with a well-upholstered body, is fitted, and has a cupboard at the back, which is capable of holding two tins of petrol and other accessories, whilst there is ample room for holding other luggage in front of the sidecar body.

The prices of the New Imperial motor cycles are as follow: Model 1, light tourist, with two-speed, 58 gns.; Model 2, light tourist, with two-speed clutch and kick-starter, 65 gns.; and 8 h.p. sidecar, 138 gns.

Stand **A.C.**

61. Messrs. Auto-Carriers, Ltd., are not exhibiting any model which will interest the motor cyclist, unless he happens to be a tradesman requiring a means of quick and economical delivery. The well-known A.C. commercial three-wheeler will be on this stand, and has a single-cylinder air-cooled engine located under the driver's seat, and driving directly to an epicyclic two-speed gear in the hub.

Stand **PREMIER.**

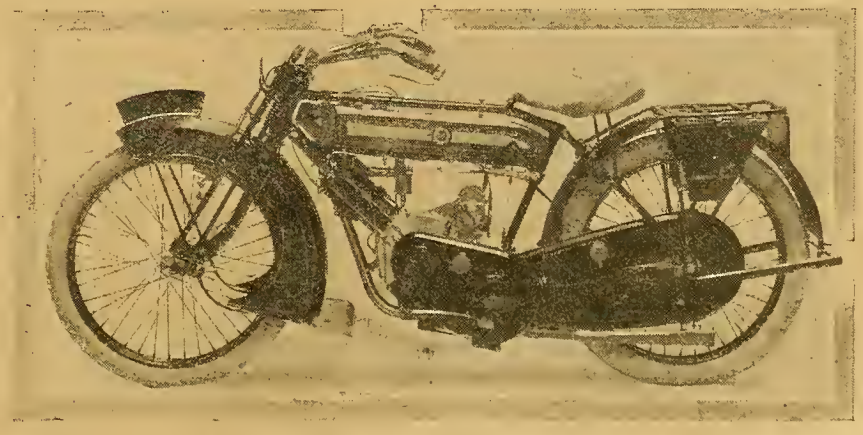
62. Undoubtedly much is expected by the public of the new Coventry Premier runabout, which will be exhibited on this stand. We described the machine in detail in our issue of October 30th, and it was again illustrated in last week's issue, among the many 1920 passenger machines then described. It is of a type which may be said to mark the top class in three-wheelers before they became over-developed into light cars on three wheels. It is fitted with a newly designed twin engine of 80×105 mm. and a three-speed gear box which has a reverse. There are several refinements not usually found on a vehicle of the runabout type, and visitors to Olympia should particularly note the single-chain adjustment and the manner in which the chain case may be opened or removed in a few seconds.

Stand **P. AND M.**

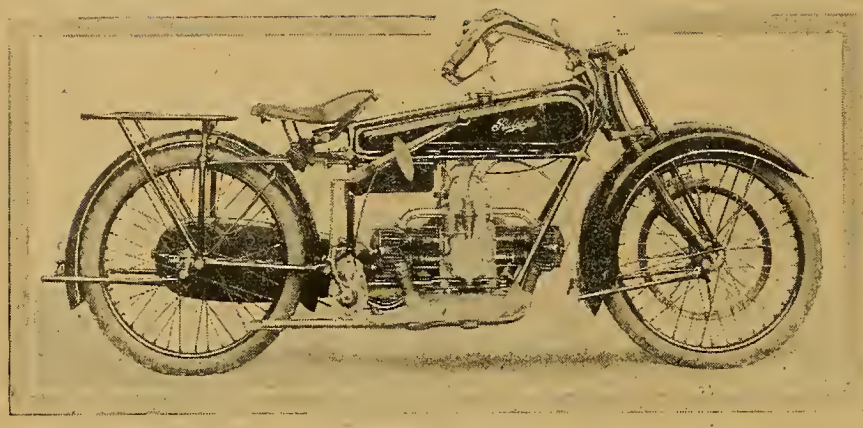
63. The Yorkshire firm of Phelon and Moore, Ltd., have always been noted for excellence of finish, crank case design especially being carried out with a view to oil retention. The normal polish on the aluminium parts also tends to make every standard machine into a "show model," and lovers of detail refinement will therefore not fail to visit this stand. One feature of special interest on the P. and M. is the ratchet lever of the rear brake, a detail often demanded by experienced sidecarists, but so far peculiar to this machine. Elsewhere in this issue will be found a report of the new mechanical details to be incorporated in the next year's programme.

Stand **RALEIGH.**

64. A slightly enlarged engine has been decided upon for the production model Raleigh which will be exhibited at Olympia. The bore and stroke are now 77 mm. and 75 mm. respectively, the total capacity being 698 c.c. The duplex spring frame is retained, as are most of the other features which charac-



Transmission side of the 1920 P. and M. Note the ratchet lever for the rear brake. An extension pipe is now fitted to the silencer.



The 1920 flat twin Raleigh fitted with spring frame and totally enclosed chain.

terised this peace model flat twin with which the old-established Raleigh Co. will re-enter the motor cycle field. A complete and illustrated description of the machine appears elsewhere in this issue.

Stand **METRO-TYLER.**

65. A most distinctive design has been produced by the makers of the Metro-Tyler for 1920. This machine is described and details illustrated in this issue.

Stand **RADCO.**

66. Alike noted for their excellent quality and reasonable price, a full range of 2¼ h.p. Radco two-strokes should attract the attention of all who are interested in a light and handy machine made on approved lines of design.

Stand **BROUGH.**

69. Owing to various manufacturing difficulties which have arisen during the year, the makers of the Brough will not be able to stage the 3½ h.p. solo model. This is to be regretted, as it is one of the few mediumweight flat twins which have been before the public for any length of time.

The 5 h.p. twin with horizontally-opposed cylinders is an ideal double-purpose mount, and several examples may be seen both with and without sidecars.

A somewhat long stroke is favoured, which is rather unusual in this type of engine, the dimensions being 70×90 mm.; the transmission is by chain throughout, a Sturmey-Archer gear box being used. Although experimental springing devices have been tried on the Brough, the makers will still adhere to the rigid frame on their 1920 models.

Stand **PARAGON.**

70. Immediately before the war the Paragon Motor Manufacturing Co., of Manningtree, Essex, was attracting some attention because of its experimental work on the two-stroke lightweight. Eschewing the usual proprietary engines, this firm decided on following its own ideas, and in the new model to be seen at Olympia many radical departures from standard practice will be noted.

Most obvious is the incorporation of the gear box in the crank case, with the magneto neatly secured behind the cylinder, thus forming a complete unit. Two speeds are used, and the control lever is mounted directly on the crank case. The flywheel is on the left side, and the transmission, contact breaker, and carburetter are all on the right, everything being readily accessible.

A small atmospheric valve in the transfer port is used to assist scavenging, and four-stroking is said to be entirely eliminated. Frame springing, on very neat and simples lines, is included, and the whole will be sold at a very moderate figure.

Stand **JAMES.**

71. Few alterations have been deemed necessary in the four models which will be retained for 1920 by the James Cycle Co. The solo machines are the 3½ h.p. V twin of 500 c.c. capacity and the popular two-stroke. The former has been exceedingly popular, and is a good representative of a type of which few are available. It is essentially a solo mount, embodying 64×77 mm. engine, three-speed countershaft gear, and all-chain transmission. The magneto is placed at the rear and well up on the frame, thus reducing the likelihood of water reaching it, should the owner elect to ride through a ford, or be compelled to ride all day in a torrential downpour of rain.

The lightweight is a distinctive little mount, having a three-port two-stroke engine of 226 c.c. capacity, which drives the countershaft by an enclosed chain on either side of the crank case. The gear is of the sliding dog-clutch type fitted close up to the engine, with which it forms a compact unit carried inside the loop frame. 24in. wheels are fitted, and the equipment generally is of first-class order.

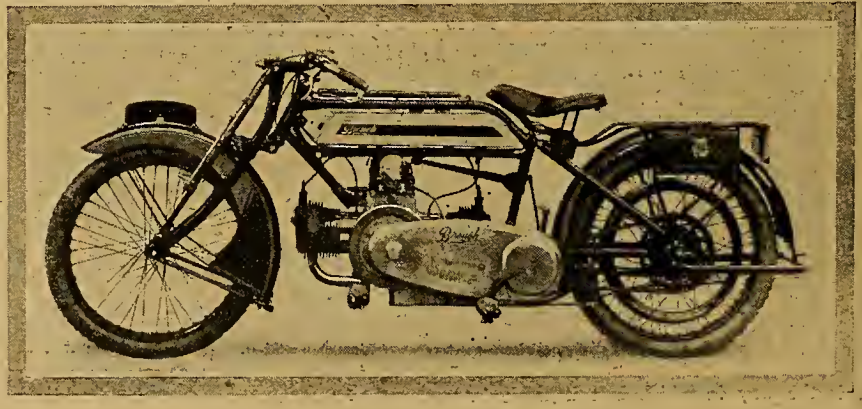
Probably the James 4¼ h.p. single requires no introduction—it is a well-known model, having an 86×103 mm. engine, with the gear-driven magneto at the rear of the cylinder. It is a sidecar machine, and, therefore, the new model appears with larger wheels and improved brakes, points tested out in the recent Six Days Trials. The countershaft gear box is of the sliding gear type, and the transmission is by enclosed chain.

The last model is the 5-6 h.p. twin outfit, which has a bore and stroke of 70 mm. and 86 mm. respectively, the total capacity being 662 c.c. This is a type of machine catering for the twin enthusiast who does not desire the great reserve of power present with the 8 h.p. twins. The sidecar fitted to this model is the James de Luxe, while to the 4¼ h.p. model a James Canoelet is standard.

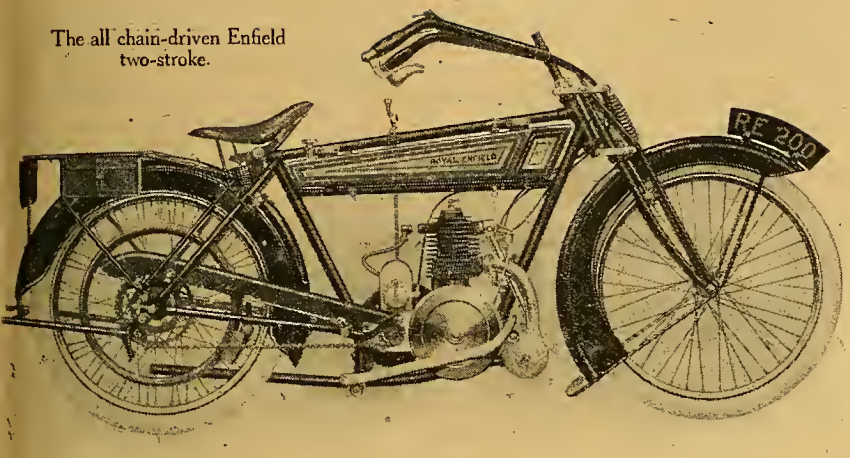
Stand **ENFIELD.**

72. Four Royal Enfield sidecar combinations will form the principal exhibit. Two of these will be fitted with the Lucas Magdyno lighting set, one of which will be equipped with the Enfield hood and screen; the third will be a standard model, and the fourth will have a tradesman's carrier attached, comprising a large coachbuilt box. J.A.P. engines, 6 or 8 h.p., are employed on these machines, and all the motor cycles on the stand will have the Enfield two-speed gear embodied in their construction. The hood shown on one of the combinations affords complete protection to the passenger, and when not in use folds back into the rear of the sidecar. The windscreen is adjustable to any angle, and secured by wing nuts.

Another feature will be the employment of the new Amac single-lever carburetter. This has been found to give excellent acceleration combined with good consumption; moreover, it simplifies control. Several two-stroke lightweights will also find a place, similarly equipped with regard to variable gear and carburetter. The engine has a bore and stroke of



The latest model 5 h.p. Brough.



The all chain-driven Enfield two-stroke.

4×75 mm. (225 c.c.). All Enfield machines are finished in black with green tanks, and have the control wires enclosed in the handle-bars. Chain transmission is also standard on these machines.

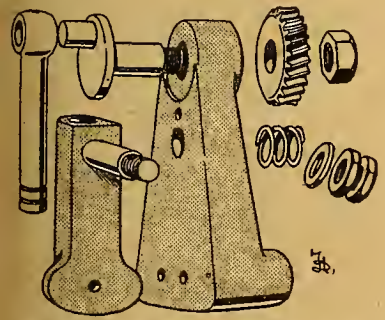
Stand **NEW HUDSON.**

74. The makers of the New Hudson motor cycles have decided on a policy of concentration for next year, and, in consequence, the 6 h.p. sidecar outfits will be abandoned for the time being. The models staged, therefore, will be entirely of the 2¼ h.p. two-stroke type, and there are two varieties, one of sporting specification fitted with footrests, T.T. bars, and all-black finish, the other having a full touring equipment, comprising valanced mudguards, aluminium footboards, leg guards, and raised handle-bars.

External finish on the New Hudson machines is extremely good, and many small mechanical details and refinements exclusive to this make are worthy of attention. Black and brown with gold lining is employed on the touring model, this giving an extremely handsome appearance.

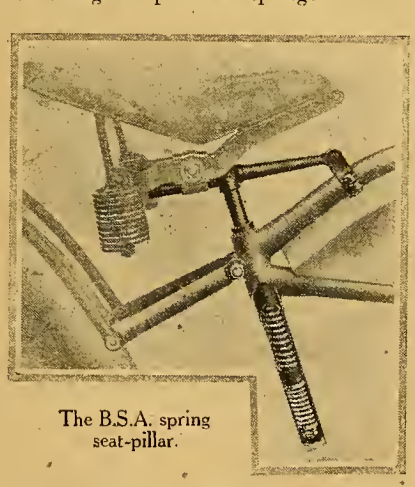
Stand **B.S.A.**

75. The most interesting part of the B.S.A. exhibit, from a motor cyclist's point of view, will doubtless be the 6 h.p.



The B.S.A. oscillating pump dismantled.

twin-cylinder machine, described recently in our columns. The engine has a bore and stroke of 76×85 mm. (770 c.c.). The valves are composed of a special nickel steel, and placed side-by-side and operated by easily adjustable tappets. The pistons are strong and light, they have two rings at the top and oil retaining grooves at the bottom of the skirt. Attached to the engine-shaft is a cush drive containing six powerful springs.



The B.S.A. spring seat-pillar.

Lubrication is by means of a mechanical pump situated in the timing gear case. Transmission is by roller chain through the B.S.A. three-speed gear box, in which all the gears are constantly in mesh and changes very easily effected. The wheels are detachable and interchangeable. Ignition is by the E.I.C. waterproof magneto, which recently came triumphantly through a very severe test, and the carburetter is an Amac. The finish is in black enamel over a rustproof foundation, and Dunlop extra heavy or Palmer Cord light car tyres (28×3in.) are fitted.

The 4¼ h.p. machine, of the type which won the team prize in the recent A.C.U. trials, will also be on view. This is fitted with the B.S.A. variable jet carburetter, and has an engine of 85×98 mm. bore and stroke, 557 c.c. (a 3½ h.p. 85×88 mm. engine is also supplied on a T.T. model).

Stand **DOUGLAS.**

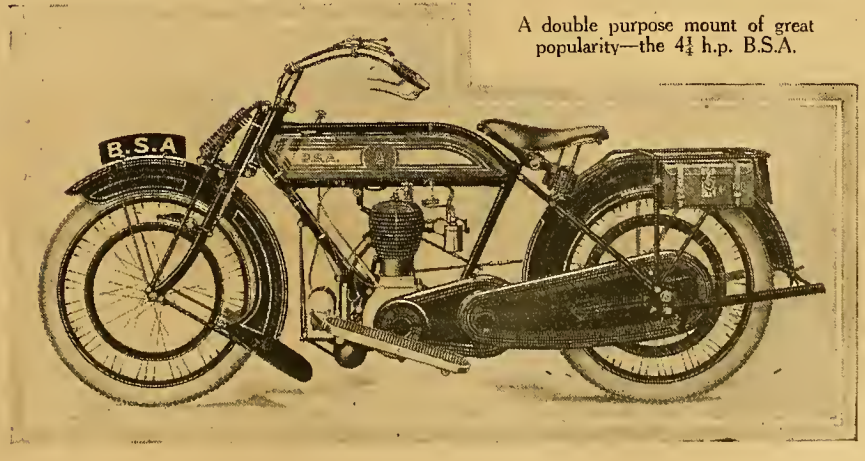
76. No doubt the greatest attraction at the Douglas stand will be the new 3½ h.p. spring frame model which, although it has been on the road and in competitions during the present year, has not formed part of the Douglas range offered to the public.

It is an entirely new model, having an opposed engine 68×68 mm. (494 c.c.) with mechanical lubrication. The specification includes a three-speed gear and enclosed kick starter, and chain-cum-belt transmission. The Amac single-lever carburetter, new type of Douglas fork, 26×2⅜in. tyres, and the Douglas spring frame, which, incidentally, has a spring system so neat that it is not immediately apparent that the rear wheel is sprung. In this system enclosed coil springs are used, which lie in a horizontal position under the tank.

The other models which will be exhibited are the 2¾ h.p. three-speed Model W and the 4 h.p. sidecar machine, both of which are well-known to the majority of motor cyclists. £90 is the price of the three-speed lightweight, and £110 for the 4 h.p. machine, £35 being charged for the sidecar. The price of the 3½ h.p. model has not yet been fixed.

Stand **SPARKBROOK.**

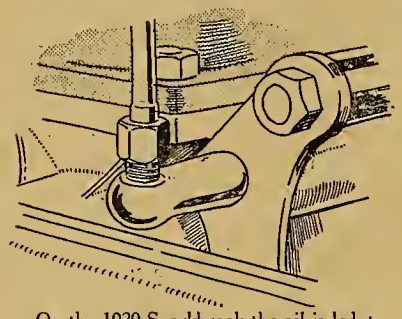
77. Fewer models in order better to produce good outputs is the general rule with the 1920 programmes of British motor cycle manufacturers. The Sparkbrook Manufacturing Co. is another firm which has decided to concentrate upon one model, whereas, before the war, it produced several. The single model for 1920 is a two-stroke fitted with a countershaft two-speed gear of the conventional type, but, as an alternative, the machine may be obtained as a single gear mount.



A double purpose mount of great popularity—the 4¼ h.p. B.S.A.

Forecast and Guide to the Olympia.—

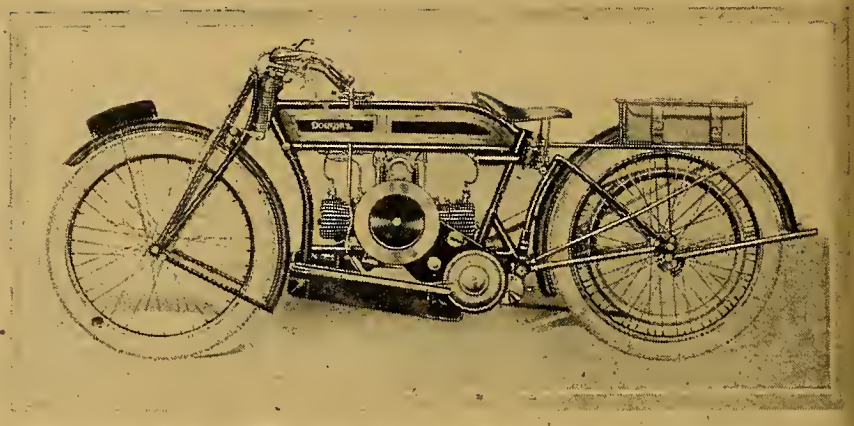
This latter machine differs in one respect from the average single gear lightweight, having chain-cum-belt transmission by the use of a countershaft. Manufactured by the Sparkbrook Co., the two-speed gear is a fine piece of work; both main and layshafts are mounted on journal ball bearings. The engine fitted is a Villiers, with a B. and B. carburetter, and the improvements over the 1919 model include a new brake pedal and stand.



On the 1920 Sparkbrook the oil is led to the engine through a hollow engine bolt and a duct in the crank case casting.

Stand **WILLIAMSON.**

78. As the sole example of 1,000 c.c. flat twin design, the 8 h.p. Williamson is noteworthy. To those who like the "top gear" type of engine, which, for sidecar work, must essentially possess the qualities of smooth running, flexibility, even torque, and good acceleration, the horizontal twin can be entirely recommended The even firing intervals give a smooth torque particularly kind to transmission and tyres, the outside flywheel assisting materially in giving ease of starting, smooth pick up, and gentle running in neutral, while such a cylinder capacity enables the engine to work well within its power and always have a reserve for smart acceleration. Air and water-cooled models are made, and chain drive is standard. A further type, embodying the 6 h.p. V twin J.A.P. engine in a similar duplex frame to the one which carries the flat twin, will also be shown.



A newly-designed Douglas model, the 3½ h.p. with an engine 68 × 68 mm. (494 c.c.)

Stand **ROVER.**

79. The chief alteration on the 3½ h.p. Rover is the all-chain transmission instead of the chain and belt drive. The primary drive is by silent chain, and the secondary chain is of the spring link type, which has been thoroughly tested out during the past year, and formed part of the specification of the 5 h.p. Rover in the recent Six Days Trials.

The spring chain is efficiently covered by a very neat guard, which protects it from mud and wet. A newly designed front fork is fitted, which is very much wider, and accommodates large section mudguards, and prevents side play developing in the fork; the front brake is also new, and acts upon a V rim. Another important departure for 1920 is that the 3½ h.p. Rover engine is now fitted with roller big ends instead of the ordinary bushes.

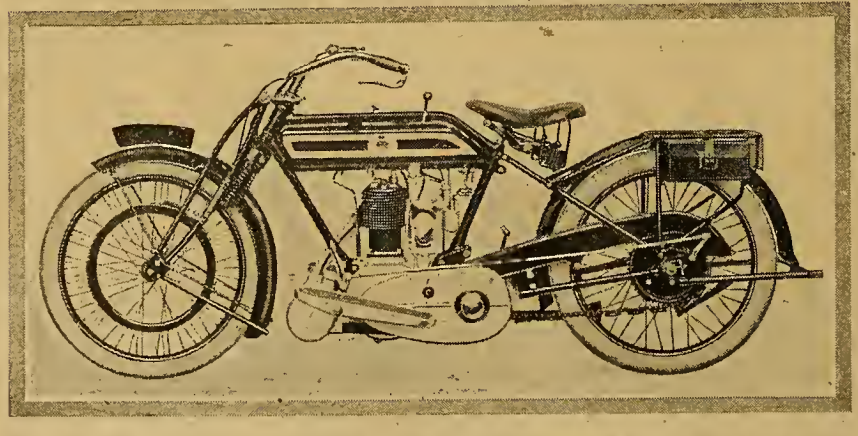
T.T. model Rovers are very much the same as they have been for the last few years, with the exception that they carry the improved front fork and front brake, and the roller big end to the connecting rod.

The 5-6 h.p. Rover motor cycle is still fitted with a J.A.P. twin engine. This model was introduced by the New Rover Cycle Co., Ltd., during the period of the war. It is fitted with the new pattern front fork, the redesigned front rim brake as described above, also the new and improved wide mudguards, while instead of the chain cases hitherto forming part of the equipment, a chain cover over the spring chain is used, giving easy accessibility for cleaning, etc.

The gear box fitted to both models is still of the previous design and principle; it has been improved, and is now fitted with a fibre ring clutch instead of the cork insets.

The chief alteration in the sidecar is the lowering of the main framework, which allows a body to be fitted which is designed on more up-to-date and roomy lines. The body is longer and wider, and has a large locker built in at the rear, which will contain a tin of petrol as well as small packages. It is upholstered in leather and painted grey, picked out in black.

The prices of the new models are as follow: 3½ h.p., with chain drive, £115, with sidecar £153; 3½ h.p. T.T., £90; 3½ h.p. T.T., with Philipson pulley, £93; 5-6 h.p., £150, with sidecar £188.

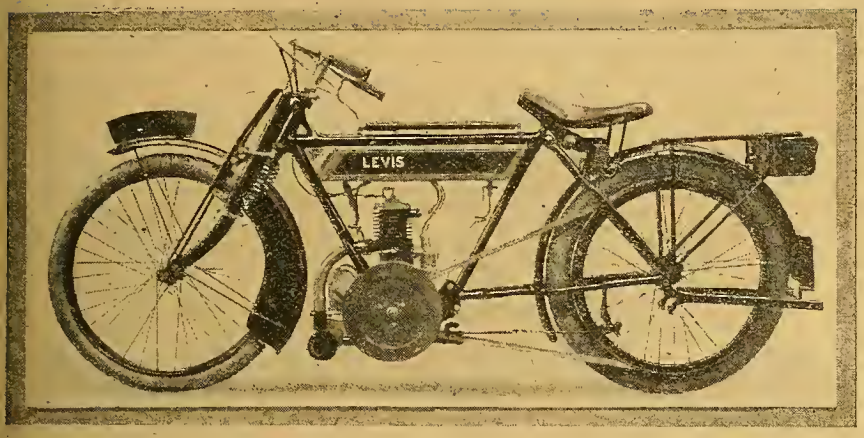


The new all chain-driven 3½ h.p. Rover. The rear chains, both in the 5 h.p. and the 3½ h.p. models, are protected with guards only.

Stand **LEVIS.**

80. Two models of the Levis two-stroke will be exhibited by Messrs. Butterfields, Ltd., one of which, however, is not likely to be marketed until towards the end of next summer, and for which orders will not be accepted. This is the new Baby model, a little 2¼ h.p. machine with an engine of 211 c.c., the bore and stroke of which are 62×70 mm.: it will interest students of small engine design. It will be observed that the magneto is at the rear of the cylinder. The frame has a sloping top tube, and, despite the fact that 26in. wheels are fitted, an exceptionally low saddle position is obtained.

Several machines of the Popular type will be on view with various patterns of handle-bars. The tank has been altered slightly, the most apparent alteration being the colour, which is now a grey with black panels and gold lines. In other details the machine has been improved. A Brooks saddle and toolbag and Dunlop tyres are now fitted. All Levis machines are now equipped with sight-feed lubricators. The price of the Popular model is £50, and deliveries will commence immediately.



Popular model of the Levis, a 2½ h.p. two-stroke.

Stand **BAT.**

82. In the distant days of motor cycle history, the name Bat was synonymous with outstanding performance in the tests of that period; at the same time, the designers of the early machines were amongst the first to study the comfort of the rider and endeavour to protect him from the effects of road vibration.

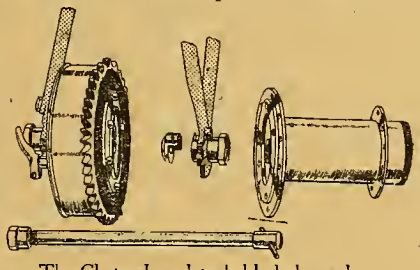
After some vicissitudes, owing to the deflection of the firm's interests from the motor cycle field during the war period, the Bat machines will be again before us—6 and 8 h.p. J.A.P.-engined models being made. They have many points of interest, the outstanding features being the fitting of the clutch to the rear hub instead of on the three-speed gear box, and the interconnection of saddle and footboards, which, by the well-known Bat system of suspension, are insulated from the rest of the machine.

A well-designed sidecar is also made to accompany these machines, which are pre-eminently suitable for heavy passenger work.

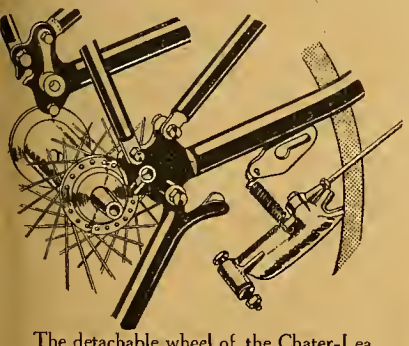
Stand **CHATER-LEA.**

83. There are no startling innovations so far as the 1920 Chater-Lea is concerned; but, contrary to reports which were current a few weeks ago, the well-known No. 7 sidecar model will be retained. Fitted with an 8 h.p. V type air-cooled engine, with chain transmission, Chater-Lea three-speed gear box and clutch, the model has proved popular, and has established for itself an enviable reputation for reliability. An important innovation, however, is the adaptation of a detachable rear wheel carried out on accepted lines, the drive being taken by means of rounded studs engaging with holes in the driven portion of the mechanism.

A new model lightweight fitted with a 2½ h.p. Villiers engine, will also be shown at Olympia. This machine also is fitted with a quickly detachable rear wheel. Immediately the spindle has been withdrawn two distance pieces riveted on to the frame are lifted up. This latter is quite an excellent feature, as it prevents the distance pieces from being lost, and also saves considerable time in either withdrawing or reinstating the wheel. Before the wheel can be finally removed it is necessary to undo the rear brake, which is accomplished by unscrewing the nut on the brake spindle and sliding the brake back in its slot as far as it will go. At the rearmost end of the hub is a hole big enough for the nut to pass through. The whole operation takes only a few seconds. This lightweight model is an attractive little mount, with a sloping top tube and comfortable aluminium footboards inclined to the correct angle.



The Chater-Lea detachable hub used on No. 7 model.

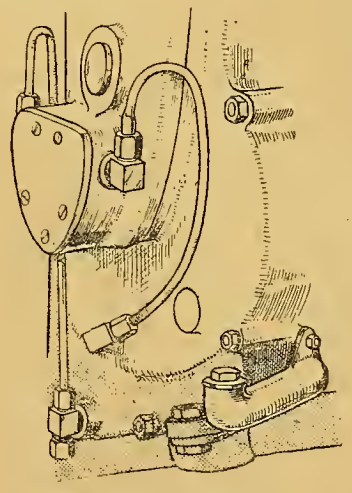


The detachable wheel of the Chater-Lea lightweight.

Stand **CALTHORPE.**

84. Two models of the well-known Calthorpe motor cycles will be exhibited on this stand—the Calthorpe-Jap, a 2¾ h.p. four-stroke with Enfield two-speed gear, and the Calthorpe two-stroke, a similar machine with the company's 75×79 mm. two-stroke (350 c.c.) engine, a feature of which is that the ports are cut into the cylinder instead of the more usual practice of casting them only. Hoffmann roller bearings are used for the mainshaft and crank pins.

The equipment of both machines includes the Enfield two-speed gear, Amac carburetter, 26×2in. Dunlop tyres, ⅞in. Dunlop belt, and patent pan seat saddle. The prices are fifty-seven and fifty-five guineas respectively for the four and two-stroke models.

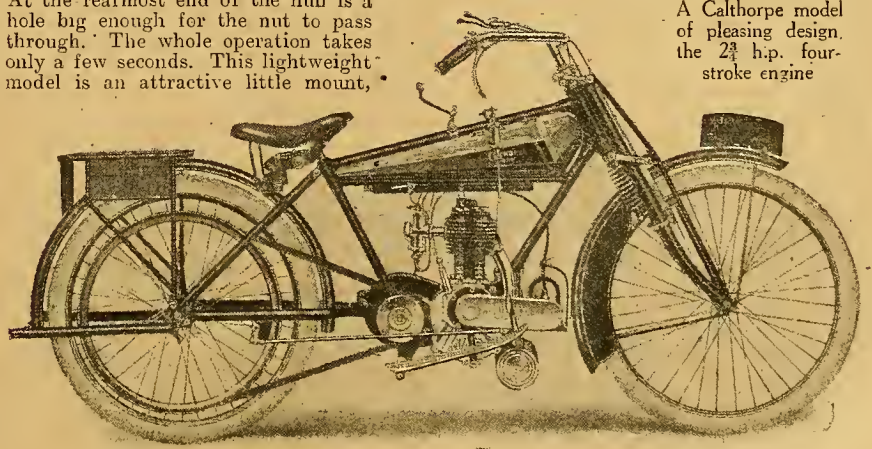


The oil pipe connections of the new 4½ h.p. Humber.

Stand **HUMBER.**

85. Many years ago the Humber was one of the first motor cycles fitted with chain drive, but lack of clutches and shock absorbers was not conducive to success. With the successful advent of magneto ignition the Humber again came to the fore, for the second time the single-cylinder holding sway, and this type preserved its ascendancy until the flat twin

A Calthorpe model of pleasing design, the 2¾ h.p. four-stroke engine



Forecast and Guide to the Olympia.—

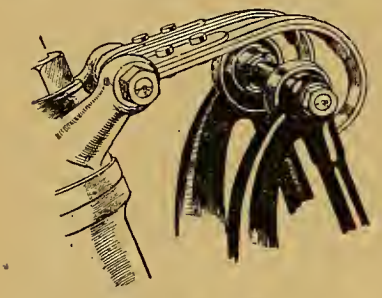
made its claims to prominence. It is significant, therefore, that the Humber exhibit will be entirely specialised, the flat twin being the only type of engine to be shown.

The 4½ h.p. machine is essentially a double purpose mount, not too heavy for solo work, but amply powerful for hauling a sidecar; it follows the general lines of the well-known 3½ h.p. flat twin, which has given great satisfaction.

A detailed description of the new model appeared in last week's issue of *The Motor Cycle*.

Stand **O.K.**

86. Messrs. Humphries and Dawes will have two motor cycle models for 1920; examples of both will be staged on their stand. The first is the new single-geared two-stroke lightweight, which has been introduced to sell at 38 gns., with first-class equipment. This machine is engined with a 2¾ h.p. Union two-stroke, a sloping top tube frame, and the O.K. spring fork, which em-



A new type of fork springing employed on the O.K.

bodies two scroll laminated springs. There are several neat fitments on the machine, and loose clips will be eliminated as far as possible.

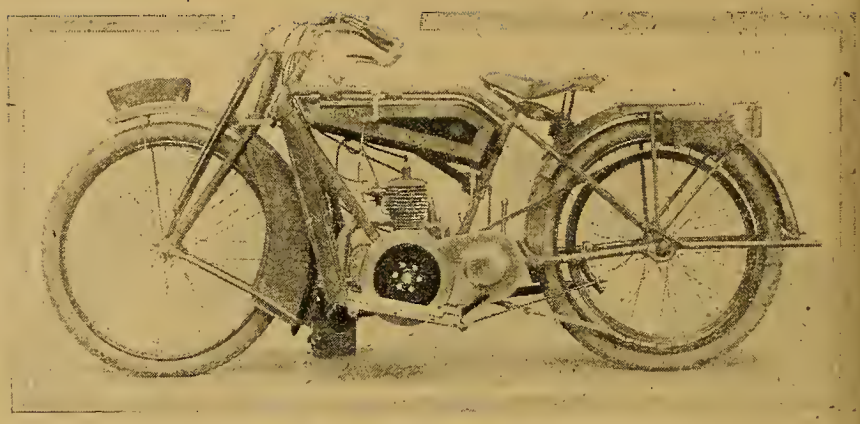
The second model is the 2¾ h.p. flat twin, which has a bore and stroke of 60 and 60 mm. respectively. Overhead inlet valves are a prominent feature, and are operated by enclosed rods and rockers from a large disc, upon which the cams are formed at the periphery.

A rather unusual design of frame is used, the tube under the tank sloping to the rear instead of being horizontal, as is the case with the majority of frames. The mudguards are wide, and the general details of the machine good.

Stand **VICTORIA.**

87. One of the few makes of British motor cycles manufactured out of England is to be seen here. The Victoria is found in two models—a 2½ h.p. two-stroke fitted with a Villiers engine, which can be purchased as a fixed gear model or is supplied with a two-speed countershaft gear with or without a clutch and kick-starter. The second model is more powerful, the power unit consisting of a 5-7 h.p. flat twin Victor engine made in Coventry. A Sturmey-Archer three-speed countershaft gear is employed, and both are fitted with Brooks saddles and Dunlop tyres.

The detail work on these machines is quite good, and no doubt Scottish riders will be especially interested in them.



The 1920 Ivy, which is fitted with neat leg guards as standard.

Stand **IVY.**

91. For 1920, Messrs. S. A. Newman, Ltd., are re-introducing the 1919 model Ivy two-stroke, with several improvements and modifications. The khaki finish, with black and gold lines, is to be retained, and the machine is rendered even more distinctive than hitherto by the addition of neat leg guards, which will be fitted as standard equipment. The footboards are of an improved pattern, and are of aluminium with a sheet rubber face, and a neat cast aluminium chain case is also fitted.

An addition to the frame is a strip steel stay under the tank, which is supported therefrom, so that there are no clips on the top tube, which gives this part of the machine a very clean appearance. As before, the duplex front is retained on the frame, and the silencer is of the spring-up type.

The silencer is of new design, and consists of a round-ended barrel built up from two steel cups which are fitted on to a central malleable portion and welded. The equipment includes Brooks B 150 saddle, Amac carburetter, E.I.C. magneto, 26×2½in. tyres, Sturmey-Archer gear with handle-bar controlled clutch, and kick starter.

Perhaps one of the most pleasing features of the Ivy is its easy starting propensities, it requiring no undue effort and scarcely any weight to start the engine by means of the kick-starter; in fact, we started it ourselves by means of the kick-start pedal by pressure of the hand. This feature makes the machine particularly suitable for ladies and elderly riders.

Stand **RUDGE.**

92. To those who aver that belt drive is moribund, the continued popularity of the Rudge at once comes as a negation. For solo work, at high speed, the smooth transmission and extreme ratios obtained with the Multi gear are a continual delight.

Several models will be staged, including the 3½ h.p., which, as a T.T. solo mount, is thoroughly popular, the 5-6 h.p. long stroke single, noted as a great sidecar puller, and the new 7-9 h.p. Multwin, which will undoubtedly attract the eye, not only of those who desire to possess the complete sidecar outfit, but of those who yearn for maximum engine capacity without excessive weight. The same characteristics, such as the well-known overhead inlet valve, multi gear, drop-pedal starter, and separate oil tanks with foot-operated pumps, are common to all the Rudge models, and are almost too well known to call for comment.

The Rudge sidecar is of very striking design, and will be available for all three Multi models.

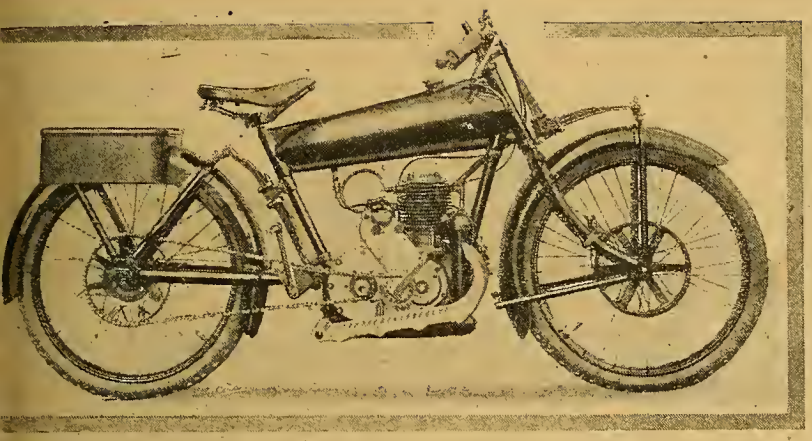
Stand **INDIAN.**

93. As in former years, the principal model marketed by the Hendee Manufacturing Co. will be the Powerplus, which is just under 1,000 c.c. and generally used with a sidecar, though some riders consider it unapproached as a "solo 'bus." The transmission is all-chain through a three-speed gear box having an excellent clutch and enclosed kick-starter. The Indian spring frame has stood the test of time, and is naturally retained. The machine is electrically equipped. The latest model destined to become very popular is the 5 h.p. Scout, which has a twin engine, 70×78 mm. bore and stroke (596 c.c.). The transmission to the gear box is by wide-faced spiral gears running in oil; thence a chain carries the power to the rear wheel, which follows English practice in its size of 26in. This machine has a duplex lower frame and is about 100 lb. lighter than the Powerplus.

Stand **PRECISION.**

95. Having specialised on engine construction since its inception, the firm of F. E. Baker, Ltd., has at last decided to market a motor cycle. Entering thus late in the arena, the 350 c.c. two-stroke Precision motor cycle at once steps into the forefront of public interest by reason of its entire independence of standard practice and conventional methods of construction.

A pressed steel tank embodies the recesses for the ends of the frame tubes commonly fitted into head and seat lugs. Except for the carburetter, flexible wire controls are eliminated, the chief operations being performed by roller levers. Gear-changing is also accomplished from the handle-bar. The two-stroke engine, which is lubricated by distribution of oil carried on the magneto chain from a reservoir in the base, has an extended

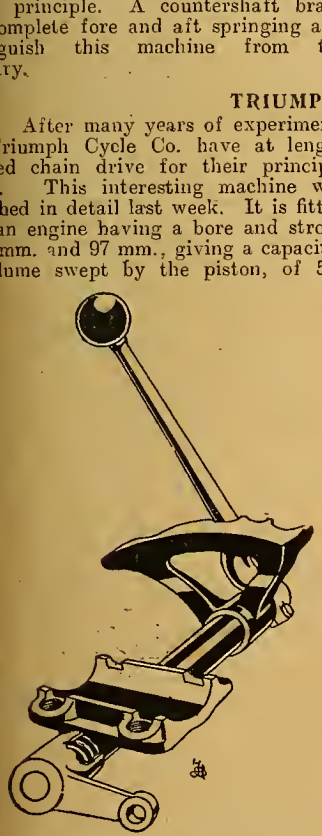


The new Precision two-stroke One of the most unconventional designs of the year

, which houses the two-speed gear. s device is on the two-chain selective ch principle. A countershaft brake complete fore and aft springing also inguish this machine from the nary.

Stand **TRIUMPH.**

i. After many years of experiment, Triumph Cycle Co. have at length ıted chain drive for their principal el. This interesting machine was ribed in detail last week. It is fitted ı an engine having a bore and stroke 5 mm. and 97 mm., giving a capacity, olume swept by the piston, of 550



The gear control of the new chain-driven Triumph.

A new gear box of Triumph design tted; this is moved, for the purpose chain adjustment, by a rack and on, and locked to the frame by four . The clutch is operated from the dle-bar, and is very smooth in action. engine is fitted with a half-com-sion lever, which is very useful for ting purposes.

he shock absorber is very ingeniously gned, consisting of a quick thread ce controlled by a spring.

The chain and belt model and the Junior Triumph, with its two-stroke engine and handle-bar controlled two-speed gear, remain unaltered.

Stand **CANOELET SIDECARS.**

98. Among sidecars the Canoelet has a name second to none, and the new models are bound to create their full share of interest, if only on this count alone. Particulars of these will appear in subsequent issues.

Stand **EDMUND.**

99. Three types of motor cycles will be staged by Messrs. C. Edmund and Co., the patentees of the well-known Edmund spring frame. It will be recalled that this system of springing embodies a separate frame for the rider, who is insulated from road shock by long laminated leaf springs, the device also including the springing of the footboards. A means of adjusting the springs is available, and improvements for 1920 include more efficient mudguarding. The three models to be exhibited will be a 2¾ h.p. four-stroke engine with a J.A.P. unit, and having an Enfield two-speed gear, and all-chain drive; a similar model with a Burman two-speed gear box, with clutch, and kick-starter, and chain-cum-belt transmission; and finally, a 2¾ h.p. Union-engined machine, similar to the first-mentioned model.

Stand **ROYAL RUBY.**

101. Several examples of the two new models will form the Royal Ruby motor cycle exhibit. The solo machine is entirely a Royal Ruby production, having a 3 h.p. single-cylinder engine. The transmission is by a chain to the two-speed gear in the countershaft, thence by belt to the rear wheel, which is fitted with 26×2½in. heavy Dunlop tyres. A kick-starter and clutch is provided.

The sidecar combination is driven by an 8 h.p. J.A.P. engine through a Sturmey-Archer three-speed countershaft gear. On the engine-shaft is placed a shock absorber of special design. The wheels are quickly detachable, interchangeable, and shod with 28×3in. extra heavy Dunlop tyres on round base rims. The rear brake is internal-expanding and the transmission by chain. The sidecar is provided with a spring wheel as well as a hood and screen, and the body can be easily removed and replaced by a tradesman's carrier in a few minutes.

Stand **CONNAUGHT.**

102. The Bordesley Engineering Co. will show four models of Connaught motor cycles, the miniature two-stroke single-speed, or two-speed with clutch and kick starter. This model has been known in the past for its excellent petrol consumption and reliability. The standard model is similarly fitted. The Connaught engine has a bore and stroke of 73×70 mm., and the capacity is 293 c.c.

Stand **CLYNO.**

103. Although the majority of motor cyclists have heard of the new spring frame Clyno big twin, few have seen it, and no doubt when it is staged on Stand 103, it will attract more than the usual crowds of sightseers. It is one of the post-war designs, and in it has been embodied many of the items of specification which have from time to time been suggested by experienced riders all over the world. It may be recalled that when the result of *The Motor Cycle* "Which type?" census was made known, it was found that the composite machine suggested by the votes of several thousands of readers was practically identical with the specification of the new Clyno

The machine has 76×102 mm. cylinders with detachable heads, 28×3in. wheels, and high ground clearance. All these wheels are sprung, and are interchangeable.

Riders of lightweights will be interested in the Clyno lightweight, which is just as distinctive as the sidecar model. For 1920 several detail improvements have been made, chief among which may be mentioned the stiffening of the frame, the fitting of Brampton forks, and the widening of the handlebars.

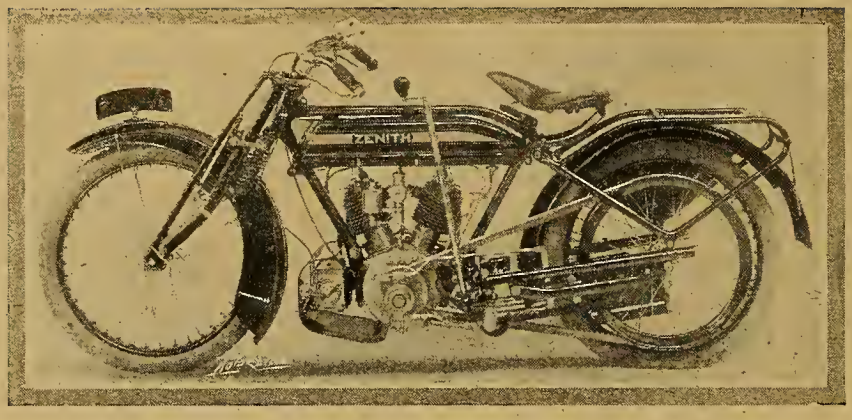
On this machine the engine is placed in an inclined position, and embodies a two-speed gear as part of the crank case. The cylinder is 70×70 mm., and the wheels are 26×2in.

Stand **ALLDAYS ALLON.**

104. This machine has a two-stroke engine of special design; the crank case is divided horizontally through its centre, and this feature enables the crank axle, connecting rod, and piston to be withdrawn in a very simple manner. A two-speed gear, combined with a clutch operated from the handle-bar, and a kick-starter are included in the specification. The transmission is chain-cum-belt.

Stand **MONTGOMERY SIDECARS.**

105. The Montgomery programme for 1920 consists of four models of sidecars of improved design. The first of these is an attractive design of coachbuilt vehicle, embodying a dash covering the body forward of the seat, and carrying a windscreen; a hood is also fitted. Several other models will be exhibited, including the tandem model which retails at the moderate price of £26 10s. Altogether, the Montgomery range should interest many buyers of motor cycles with which sidecars are not supplied, and those who prefer something different from the standard sidecars supplied by the makers who catalogue complete outfits.



Standard model of the 5 h.p. Zenith, embodying the Gradua gear driving directly to the rear wheel.

Stand **HOBART.**

136. The 1920 Hobart lightweight is one of the several new machines which will appear at Olympia fitted with a spring frame. This device is quite a neat fitment located behind the seat tube, and is the result of several years' experiment and test. The engine fitted is a Villiers two-stroke. The spring frame model is fitted with a two-speed countershaft gear, kick starter, and a handlebar controlled clutch. Single gear and two-speed models will be shown without the spring frame, and a new model with 2¾ h.p. J.A.P. engine and two-speed gear will be exhibited.

Stand **HAZLEWOOD.**

107. A new Hazlewood sidecar machine will be welcomed by those of our readers who rode Hazlewoods before the war. The 1920 model is a 6 h.p. twin, with cylinders 70×85 mm.

It is similar in nearly all respects to the pre-war model, having a chain and belt drive and a three-speed countershaft gear. Quite an unusual feature is incorporated in the fixing of the belt rim, which is spoked to a separate hub and bolted to the main wheel hub. A powerful head lug includes provision for two sidecar attachments, and a stout additional stay serves to relieve the lug of unnecessary strains.

Stand **ZENITH.**

108. Long famous for the Gradua gear, the Zenith motor cycles hold the goodwill of a large section of keen motor cyclists. Since the specification of these machines has not varied from the main characteristics of the design for many seasons, it follows that the demand for the type of transmission employed has in no way diminished. Given a powerful engine and a gear infinitely variable between its limits, no more delightful mount can be made; its appeal is without doubt essentially to the man who desires speed. A new model will be keenly inspected; as recently described in *The Motor Cycle*, it is a 2¾ h.p. horizontal twin, and, although a chain-driven countershaft is embodied in the transmission, the Gradua gear is fitted. 5 h.p. solo and 8 h.p. sidecar models will be made during 1920, both of them incorporating the V twin J.A.P. engines.

Stand **READING STANDARD.**

110. As an American machine which has long conformed more closely to English ideals than most of those coming from beyond the Atlantic, it is with considerable interest that we anticipate its importation during 1920. While the general details follow conventional American practice, the side-by-side valve arrangement, right-hand kick starter, and general cleanliness of outline, should appeal particularly to the rider who favours the average British layout.

Interconnected clutch and gear control, dynamo lighting, twist-grip operation of throttle and ignition, and mechanical lubrication are features of this machine, which, incidentally, has one of the largest engines in the Show, this being rated at 10 h.p. on a capacity of 1,170 c.c., the bore and stroke being 85.7×101.6 mm. respectively.

Stand **DOT.**

113. Assembled with J.A.P. engines and standard components of sound design, the Dot machines will be presented in both lightweight solo single, and high-powered twin passenger models. The smaller machine, which has a 2¾ h.p. engine, is a taking little mount on standard lines, with chain and belt transmission.

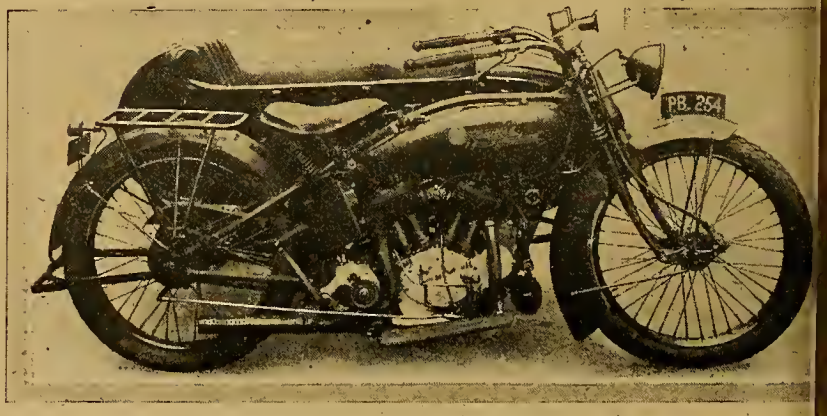
The passenger machines, with the larger V twin J.A.P. engine, are equipped with handsome sidecars on graceful underslu chassis. On these models the transmissi is by semi-enclosed chains, through Sturmey-Archer three-speed gear box a hand-controlled clutch. A rich dark r enamel is used in the finish of th machines, which present an extrem smart appearance.

Stand **NORTO**

115. Advocates of the long str engine will make a point of visiting t stand, which will contain the most nota examples of this type of constructi The 3½ h.p. Norton has a bore and str of 79×100 mm. (490 c.c.), and it is nowned for its wonderful turn of spe The Brooklands Special and Brookla Road Special are both timed at Bro lands, and every individual engine certified to have exceeded 75 and 70 m.p respectively. The above models, toget with the T.T. Norton, are sing geared and belt-driven. The Spo model is chain-driven through a thr speed countershaft gear, provided w a hand-controlled clutch. The Nor Big Four (82×120 mm. bore and stro 633 c.c.) is a fine sidecar machine hav great power, and while it is not desig for very high speed, can comforta exceed 40 m.p.h. with a sidecar. T Norton engine is very economical in f consumption, extraordinary results this line having been obtained.

Stand **N.U**

116. The long looked for post-w N.U.T. will be a great attraction on stand of the Newcastle-upon-Tyne Mc Co., as it is one of the *de luxe* s machines for 1920. The policy of the f is to offer a solo machine which sh be complete in every way, with th many refinements usually purchased the keenest riders as separate items added to their mounts. This equipm includes a Magdyno combined light and ignition set. The engine fitted a 500 c.c. twin made specially for N.U.T. Co. by Messrs. J. A. Pr wich, and has a bore and stroke of (and 76 mm. A plain bearing is u on the timing side and ball beari on the driving side. Automatic pressi feed lubrication from a sump in crank case is a feature of the eng which has side-by-side valves and justable tappets. An exceptionally la aluminium silencer is fitted below engine, from which the exhaust g



Compactness of design is a noticeable feature of the 10 h.p. Reading Standard.

ons of petrol can be carried at one
ng will be a point appreciated by
e who make long journeys.

ark II. Druid forks, Palmer cord
2½in. tyres, Brooks saddle and pan-
bags form part of the equipment,
the price will be 120 gns.

ıd **HARLEY-DAVIDSON.**

7. Few alterations are to be noted
he new Harley-Davidson model. The
will be showing their powerful twin-
nder, which is so popular among users
idecars, and their sports model, which
described recently in *The Motor*
le.

o far as the larger type of Harley-
idson is concerned, more substantial
ns, chain guards, and sprockets will
fitted for 1920. The silencer is of
ter dimensions and has been slightly
red in design, so as to give greater
ıce and higher efficiency. The firm
still adopting the Remy system of
ting and ignition.

sers of Harley-Davidsons will remem-
that in previous years there has
ays been a danger of running down
accumulator by leaving the switch in
on and the contact-breaker points
hing. This may be avoided by con-
ing up the horn, so that, unless
act is broken, the horn will sound.

feature of the exhibit will be the
fortable English-made sidecar bodies
which the twin-cylinder machines are
d. They are provided with a
er in front and pockets on both sides.
tops of the bodies are of polished
d and look extremely handsome. In
tion to the electrical model, the
neto model Harley-Davidson will also
hown.

Stand **WOLF.**

118. Four Wolf motor cycles will be staged by the Wulfruna Co., who, for several years, have specialised in light-weights. Two of these machines will be fitted with Villiers engines and two with the 2¾ h.p. J.A.P. unit. The two-strokes are fitted with Albion two-speed gear, and with a two-speed gear embodying clutch and kick starter, the J.A.P.-engined models having a two-speed gear and a Sturmey-Archer unit with clutch and kick-starter.

Stand **DIAMOND.**

119. Diamond 1920 models, which will be exhibited at Olympia, depart very little from the standard models of 1919. They will be shown fitted with J.A.P. and Villiers engines, and Enfield and Sturmey-Archer gears. The re-introduction of the pre-war shaft and chain-driven model is held up for the time being, as is also an interesting type of machine embodying a pressed steel frame.

Stand **MORGAN.**

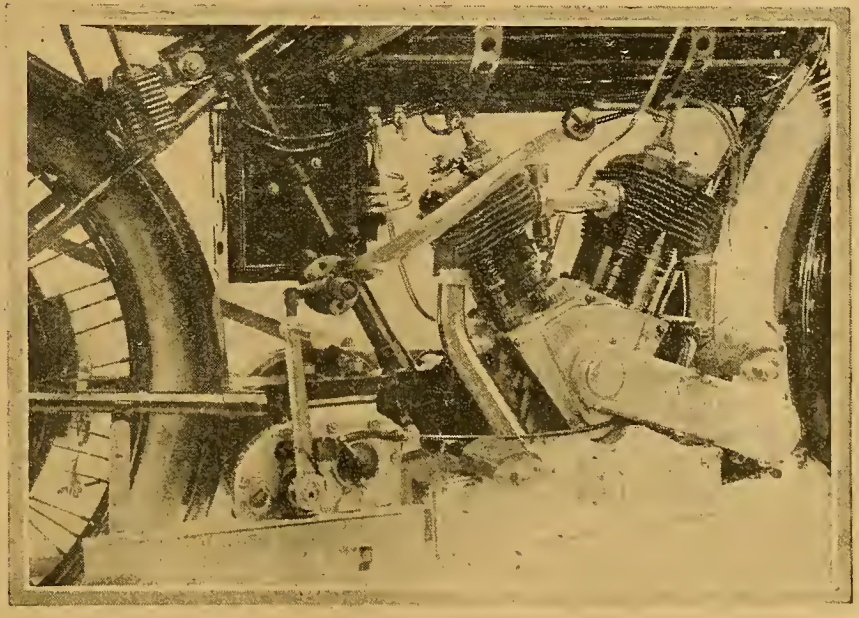
120. Only one Morgan chassis is made by the Morgan Company, the variation in the different models being in the make of engines fitted and the types of body-work. Three main models will be provided for 1920, the Grand Prix—a water-cooled model on more or less sporting lines—the standard touring machine, with air or water-cooled engine; and the family runabout, which is fitted with two extra seats for children. There are several improvements in details, including the fitting of a ball thrust in the clutch withdrawal mechanism, longer bearings in the steering heads, and stronger bevels in the gear box.

Stand **QUADRANT.**

121. Two single-cylinder sidecar machines will form the chief items of the Quadrant Co. for 1920. These machines were fully described in our issue for October 30th. The first has a bore and stroke of 87×110 mm. (654 c.c.), and embodies a Sturmey-Archer gear and all-chain drive; and the second has a 95×110 mm. (780 c.c.) engine with which the three-speed gear box is built integral. Sloping top tube frames and saddle tanks form part of the specification.

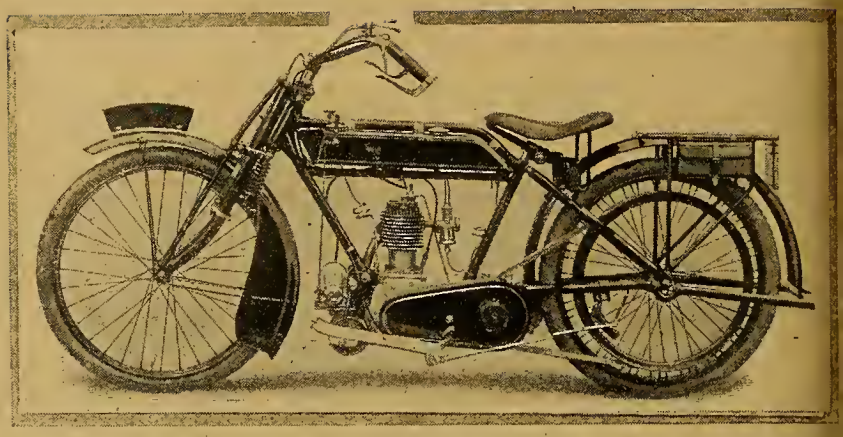
Stand **SCOTT.**

122. On the Scott exhibit will be shown four complete motor cycles, two being standard machines, one sports model, and a sidecar outfit. This well-known two-cylinder water-cooled two-stroke is too well-known to need description, but the exhibit nevertheless will not fail to interest every visitor to Olympia. To satisfy the curiosity of the vast number of motor cyclists who have not closely examined the working parts of the Scott engine, a complete set of parts will be exhibited, which will reveal the automatic oil system, the special fixing of the gudgeon pins, and method of securing cranks and flywheel. Sectional engines and gears will also be exhibited.



Valve side of the new N.U.T. power unit. Note the unconventional design of the silencer.

How the 1920 Scott front forks are lubricated.



2¾ h.p. J.A.P.-engined Wolf, fitted with two-speed gear.

Stand **OLYMPIC.**

123. Although the name Olympic is not so well known as perhaps are the majority, the men behind the Olympic Co. have old connections with the trade, and more will be heard of it in the future than has been the case in the past. The old-established Olympic concern has recently been acquired by Mr. W. J. Clarke, who for many years was manager of the Wulfruna Engineering Co., and also of the Wearwell Cycle Co. One of the two motor cycles included in the exhibit is fitted with a Villiers two-stroke engine, Brampton forks, and Burman two-speed gear, with clutch and kick starter, while the second is a four-stroke of 2¾ h.p., with outside flywheel.

Stand **VINDEC.**

164. In addition to a large range of accessories of every sort and description, Messrs. Brown Brothers, Ltd., will be showing the Vindec two-stroke motor bicycle, fitted with two-speed gear and chain-cum-belt drive. This is a well-equipped and well-tried little mount which cannot fail to be popular. The enclosed chains and the well valanced front mudguards are features which will be appreciated by our readers. Another excellent point about this machine is the spacious toolbag fitted to the side of the carrier.

Dinner to the Imperial Motor Transport Council.

H.R.H. Prince Arthur of Connaught and Officials and Members entertained by the Association of British and Allied Motor Manufacturers.

ON Wednesday of last week the Association of British and Allied Motor Manufacturers entertained H.R.H. Prince Arthur of Connaught and officials and members of the Imperial Motor Transport Council.

Mr. H. C. B. Underdown was in the chair, and there were approximately 150 guests.

After the toast of "The King" had been honoured, the CHAIRMAN proposed "The Guests," and referred to the fact that the Imperial Motor Transport Council was first founded in 1913, and at the first meeting 200 delegates took part. On that occasion the subject of fuel supplies and transport for military purposes was discussed.

He wished to assure the members of the Imperial Council that the interests of the British motor manufacturers in Overseas trade was unabated, and that they intended to do all they could to recapture the goodwill largely lost owing to the war. They were also very glad to have present Sir Hamar Greenwood, head of the Department of Overseas Trade—a Department which stood out as a striking proof of the wish of the Government to assist our export trade.

The Work of the A.B.M.A.M.

He would like to explain that the Association of British Motor and Allied Manufacturers worked with the Society of Motor Manufacturers and Traders in the very friendliest manner, and would very soon be probably a part of it.

Among the many tasks which the Association had undertaken was the standardisation of parts, which ought to be common on different types of vehicles, and it undertook the discussion and distribution of the products of its members in a manner fair to the markets, fair to the manufacturer, and fair to the distributer. Furthermore, it had succeeded in founding a Research Association, with the assistance of the Government, and it could claim to be the first engineering association to have done so. It had also made arrangements with the Department of Overseas Trade for an investigation as regards their interests abroad.

Costs and Prices.

Among other matters mentioned in the course of a long speech, the Chairman touched upon the question of prices and costs—which, incidentally, apply equally to the motor cycle industry. This was a question about which there had been many criticisms, he said. They were accused of overcharging. The Association had, however, been at considerable pains, assisted by expert advice, to ascertain how the rise in the cost of production compared with the rise in prices, and after an examination of the figures it was found that present prices far from counterbalanced the increased cost of production. Steel of all kinds was nearly three times as much as in 1914, aluminium more than twice, timber three and a half times, and labour had more than doubled in cost; also, a further 5s. had been granted recently to workmen. Further, they were at the moment at a standstill, owing to the lamentable moulders' strike, which must necessarily upset a great many plans and programme for 1920. Management and distribution expenses had increased proportionately with the increase in the cost of material and labour, but prices had barely doubled. Had they been doubled, they would have been fully justifiable.

H.R.H. PRINCE ARTHUR OF CONNAUGHT, K.G., K.T., paid tribute to the quality of British cars. Without the motor transport he did not believe the war could have been carried on to a successful conclusion.

War history revealed in a very large measure the success of our lorries in supplying rations and ammunition to our troops in the field, and to enable our Commanders to bring up reinforcements to a threatened point in the shortest possible time on many eventful occasions.

MR. EDWARD MANVILLE, M.P., remarked that there never was a time when the prospects of those who manufactured material for transport were as good as they are to-day. There were perhaps one fly in the ointment, and that was the attitude labour may take towards the industry in general. Employers and employed must work for the mutual benefits of both.

SIR HAMAR GREENWOOD, BART, M.P. and the HON. SIR ARTHUR STANLEY, G.B.E., C.B., also spoke.

NEW MODELS.

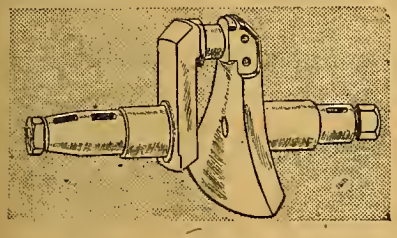
THE 1920 METRO-TYLER.

A Newly-designed 270 c.c. Two-stroke with Unit Assembly of Engine, Gear Box, and Magneto.

THE 2½ h.p. Metro-Tyler two-stroke has been completely redesigned for 1920, and but few of the original details, which made the early machines of the same make so successful in such a short period, have been retained.

It will be manufactured in one standard model only, and this has a surprisingly neat and compact appearance, since the engine, gear box, and magneto are in one complete unit, which is mounted between two steel plates forming a housing.

Of the three-port two-stroke type, and having a bore and stroke of 70×70 mm. (270 c.c.), the engine has a cast iron cylinder fitted with an inspection port over the transfer passage. Special attention has been paid to ensure the adequate cooling of the combustion head, insomuch that the three top cooling fins are of aluminium, which rapidly disperses the heat generated. The cylinder head is machined both on the inside and outside.



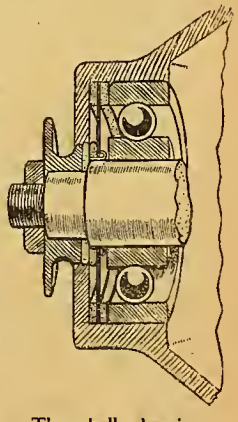
The one-piece crankshaft, showing the housing for the plate which secures the rollers in the big end bearing.

The crank case is ingeniously constructed, the design having been carefully considered in order to provide and maintain a high initial compression. The use of large diameter Skefko ball bearings necessitates some device to maintain compression within the crank case, and in this case the one evolved consists of spring diaphragms with bronze faces in contact with floating steel washers, which latter are held in position on either side of the crank case by the magneto and chain sprockets respectively. The diaphragms are held between two fibre washers, the outer one being of greater width than the inner one, thus distorting the diaphragm, and holding it tightly against the floating washer. Should wear take place, the washers may be changed over, and will effectively take up the play. The crankshaft is a one-piece steel stamping, and is provided with an integral balance weight. By accurately grinding the bevelled edges of the crankshaft webs and the rounded edges of the big end, the connecting rod may be passed over the shaft and placed in position to accommodate the rollers of the bearing. The big end of the connecting rod embodies the outer ring for the rollers, whilst the crank forms the inner member. This bearing has no cheek plates or rivets. The retention of the rollers in position is effected by means of a plate which is screwed to the corresponding area cut out of the crankshaft stamping.

Piston and connecting rod of the new Metro-Tyler engine

The connecting rod is bushed at the small end, and the gudgeon pin is secured to the cast iron piston by means of a set screw and locking pin.

New ideas are noticeable in the design of the decompressor, which is housed in the front of the cylinder, and directly opposite the sparking plug. By removing these two parts a clear way is made across the top of the piston, which allows the removal of carbon deposit without dismantling the cylinder.

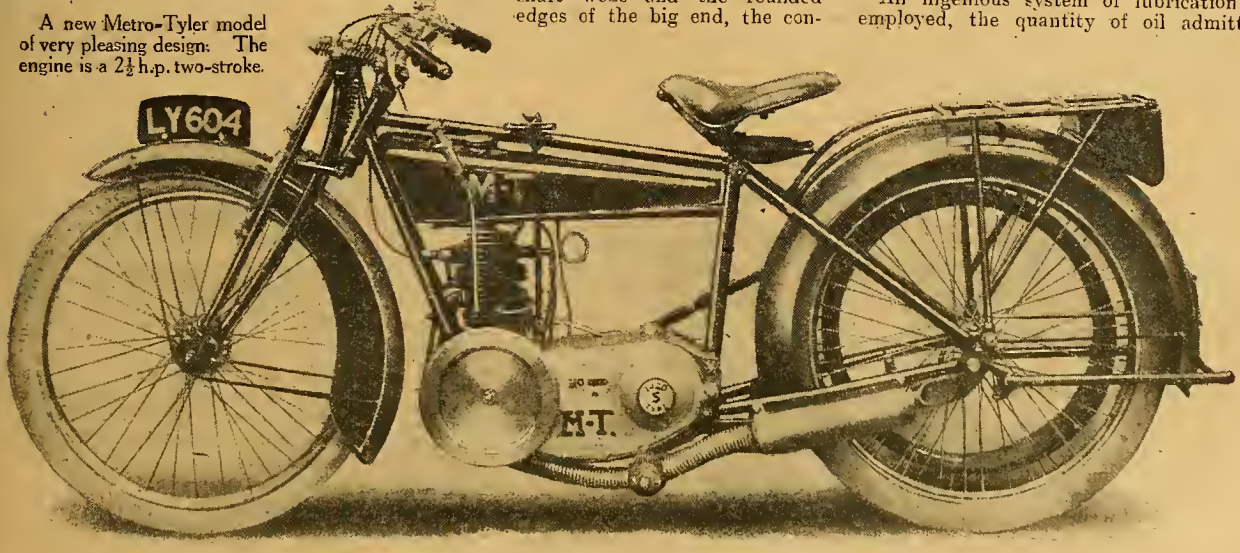


The ball bearing supporting the main shaft.

The construction of the decompressor, which releases directly into the exhaust pipe, is clearly shown in the illustration.

An ingenious system of lubrication is employed, the quantity of oil admitted

A new Metro-Tyler model of very pleasing design. The engine is a 2½ h.p. two-stroke.



New Models.

to the engine being regulated by the adjustable drip on the Enots lubricator, whilst the supply is maintained by suction from the induction pipe.

A spiral oil groove is cut in the cylinder wall, one end of which is connected to the induction pipe, and the other to an oil lead from the lubricator.

The cone compression release valve.

A proportion of the oil which is sucked into the spiral groove lubricates the piston and gudgeon pin, which latter is drilled and grooved, and eventually passes through the induction port in the cylinder into the crank chamber; the remainder of the oil, however, is drawn into the crank case, and there lubricates the crankshaft ball and roller bearings. Should it be found necessary, an auxiliary hand pump is provided, whereby the supply of oil may be augmented. The two-speed gear box, which is completely concealed by and housed in the side plates, follows standard practice. Special attention, however, has been paid to lubrication and the method of engaging the dogs employed. The same oil as is used for engine lubrication is employed in the gear box, a large filler cap being located on top of the casting.

Efficient Gear Box Lubrication.

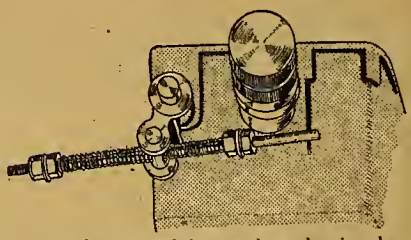
In addition to the oil holes drilled between the constant mesh gear teeth for lubrication of the bushes, the splined shaft has a left-hand spiral cut in the bearing end which leads to the straight oil channel cut in the splined portion.

The two gear ratios employed are 9.84 to 1 low gear, and 5.25 to 1 high gear.

In order that the dogs may be gently engaged, a control lever embodying a spring device is employed, which, regardless of the dog's position, may be moved around the quadrant fitted above the petrol tank.

The gear box may be moved along slotted holes drilled in the side plates for chain adjustment, whilst the C.A.V. magneto, which is secured to an aluminium bracket between the engine and gear box, may be adjusted in a similar manner.

Accessibility forms one of the most prominent features of this new machine, the complete power unit may be removed from the main frame in a few minutes, the chain cases are detachable for chain adjustment, and an inspection cover is provided for magneto adjustments.



A plan view of the gear box, showing the large filler cap and the spring gear lever control.

The petrol tank, which is of very pleasing appearance, has a capacity of one and a half gallons, whilst the small oil compartment contains one quart.

The price of the machine, deliveries of which will commence early in February next, is not definitely fixed. It will, however, be somewhere in the vicinity of sixty-seven guineas.

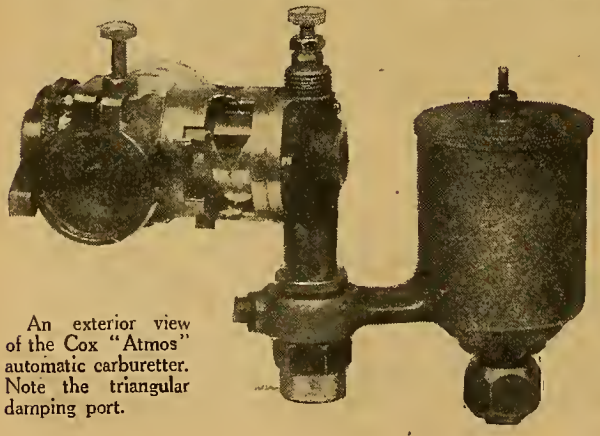
The Cox "Atmos" Carburetter.

A Scientifically Designed Instrument giving Maximum Power, Speed, and Economy, with One-lever Control.

CARBURATION is a subject of perennial interest, and experimentalists in its field are innumerable; all claim to have the perfect instrument, but in one direction or another a weakness is usually to be found—high petrol consumption, a flat spot, bad slow running, or starting singly or collectively appearing.

The inventor of the Atmos carburetter has approached the question from a deductive standpoint, and, basing his experiments on past experience with carburetters more or less conforming to standard practice, he determined to branch entirely away from the lines on which he had worked hitherto.

Regarding first the failure of most automatic carburetters to register good consumption, except at one speed, deduction led to the belief that the placing of the jet in the main air stream was wrong, since in this position it is subject to widely varying conditions.



An exterior view of the Cox "Atmos" automatic carburetter. Note the triangular damping port.

The reason for the disproportionate supply of petrol at high speeds in the average carburetter is, of course, due to the fact that sufficient air is unable to pass through the choke in a given time, consequently the depression in the induction pipe increases, and too much petrol issues from the jet.

If, instead of placing the jet in the main air stream, we could place in the narrowest part thereof the orifice of a tube conveying gas, the latter would be drawn along at a rate proportional to the speed of the main air. This arrangement is achieved in the Atmos carburetter by placing the jet in a small venturi tube, which opens into the narrowest part of the main choke, at the centre of the rotating throttle barrel.

Operation of the engine causes a depression in the induction pipe, and, according to the intensity of this, air passes at greater or less speed through the main choke. The speed of this air flow determines the speed at which air shall be induced through the subsidiary venturi. A second depression is here caused, but this is not proportional so much to the depression in the induction pipe as to the speed of the air flowing through the main choke, consequently petrol is sucked from the jet in proportion to the amount of air passing through the carburetter. The above reasoning applies chiefly to the case in which the throttle is fully open, and to obtain perfect results at all speeds further experimenting was involved.

Since the jet is not directly subject to the main depression created in the induction pipe, but delivers petrol in proportion to the depression in the smaller venturi, and as this depends in turn on the velocity of the main air stream, it follows that if the speed of the air flow through the former can be controlled, the fuel flow could likewise be determined.

At small throttle openings the tendency for the main depression to extend towards the second venturi, and act directly on the jet, is counteracted by an annular ring of triangular ports surrounding the smaller choke. These ports register with ports in the throttle, of such a shape that, as the throttle opening widens, the ports close. By this device the speed of air flow through the smaller venturi,

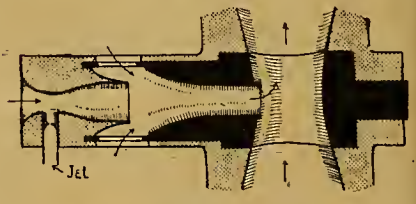


Diagram of the air passages. The shaded portion is the stationary part of the body, and the throttle with its extension, which contains the air regulating ports, is shown in solid black.

and with it the flow of petrol to the engine, is gradually increased to a maximum as the throttle reaches the fully opened position.

New Models.

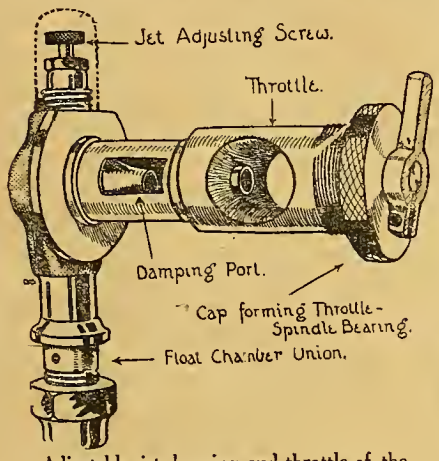
Externally the Atmos carburetter has a somewhat complicated appearance, but in actual construction it is exceedingly simple. The inventor has exhaustively studied the subject of carburation, and, in consequence, has evolved an instrument in which the supply of petrol is controlled by air velocities through the internal passages; this fact enables a single jet or fuel orifice to be used. The main air flow through the carburetter being controlled by the throttle, no air valves are necessary, and the throttle is the only moving part.

A float chamber of conventional pattern is used, communicating with an adjustable jet. The latter is never varied under running conditions, and once set to give best maximum all out power is locked; this setting depends upon the size of the main choke and *not* upon the size or type of engine. Once the carburetter is set, no alteration can be made advantageously, whatever the variety of engine to which it is applied. A small shutter is fitted to cover the damping ports surrounding the smaller venturi; this is only used for starting purposes and eliminates the necessity for flooding.

Some Comparative Tests.

The inventor's claim that a perfectly automatic carburetter can be regulated by air velocity only without the use of mechanical devices like dash-pots, suction valves, or variable jets, is borne out by the actual performance of the Atmos. It is further argued that the carburetter which is once set, if truly automatic in action, should function perfectly within its range on an engine of any type or size, and not show an excessive consumption if used on engines of much larger dimensions than the one to which it would normally be fitted.

We witnessed the following test. A small untested carburetter was taken and the jet adjusted to the position known to be most suitable to the bore of the main choke. This was fitted to a V twin engine of 85×95 mm. bore and stroke and the engine started up. This was effected with one or two turns of the crank, and the following points were noted. Starting was easy and certain, slow-running exceptionally good, pick-up running light and also, when heavily loaded by a rope brake on the flywheel, instantaneous, "hunting" being entirely absent. Consumption indicated by flowmeter was proportionate throughout the speed range.



Adjustable jet, housing and throttle of the Cox "Atmos" carburetter. The throttle is the only moving part.

Meanwhile, a four-cylinder lorry engine of 105×140 mm. bore and stroke was being warmed up on a large Atmos, and the same characteristics were observed; the fuel consumption was also noted at a given load and engine speed.

An Amazing Result.

Both engines were then stopped and the small carburetter was taken from the twin and fitted (without any alteration) to the big four-cylinder. The latter instantly started with a turn of the handle and showed the same results as those obtained from the correct size of carburetter, except that the maximum speed was limited.

In this case the engine was loaded to the same degree and speeded up to the rate of revolutions at which the consumption had been noted with the large carburetter, and it was interesting to see that the flowmeter reading was almost identical with the one previously obtained.

No more conclusive proof could be given of the inventor's contention that a carburetter could be set within itself to give a perfect mixture at all speeds and loads, irrespective of the engine to which it is to be fitted.

The motor cycle models of this instrument are not yet available, but, meanwhile, we hope extensively to test one on a machine well known as a difficult proposition from the carburetter maker's point of view. We shall give our readers the result of our further experience with this interesting instrument in due course.

The T.B. Three-wheeler.

A Shaft-driven Runabout by an Aircraft Engineering Firm.

THERE are several new three-wheelers of which the public has not yet been advised, some of which are the products of large engineering firms with excellent facilities to manufacture a first-class article at a reasonable price.

The T.B. three-wheeler is a proposition now offered by one of these firms—Messrs. Thompson Bros. (Bilston), Ltd.—who, during the war created a large aircraft department, which, now released for civil work, will be devoted to the three-wheeler illustrated.

Experimental work has been in progress for the past twelve months, and the production model evolved has completed a strenuous road test of several thousand miles, during which, we are told, no adjustments or alterations were made to the car.

Shaft Drive.

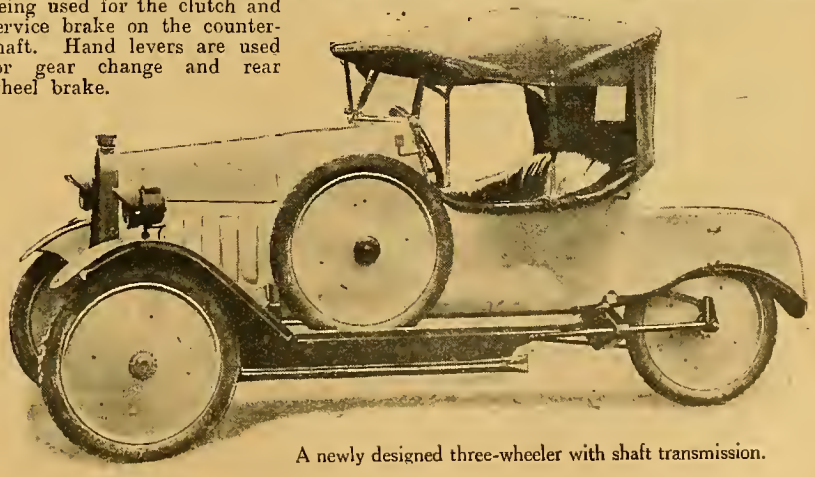
Probably the transmission is the most interesting feature of the vehicle, as shaft drive is used throughout. The engine—an 8 h.p. J.A.P. or a 10 h.p. Precision twin—is built up integral with a two-speed and reverse gear box of the company's own design. This embodies a large diameter leather-to-metal clutch, incorporating a patent spring drive. The unit is easily accessible, and can be detached quite readily from the chassis. Universals of the disc type are placed at either end of the propeller-shaft.

The frame is of tubular construction, and is fitted with quarter-elliptic springs at the front axle and long cantilevers at the rear. Metal is used practically throughout the body construction, which is quite pleasing in design, and has a hinged tail-piece to facilitate the removal of the rear wheel.

Steering is direct, and the carburetter and ignition control is carried to the steering wheel by Bowden wire—pedals being used for the clutch and service brake on the countershaft. Hand levers are used for gear change and rear wheel brake.

The engine is started by a handle at the front of the machine, and the equipment includes Amac carburetter, M-L magneto, Best and Lloyd semi-automatic drip feed lubrication system, spare wheel, hood, screen, lamps, and pump.

At a later date we intend to deal more fully with this interesting machine. In the meantime, it suffices to say that the makers contemplate starting deliveries in January, and that the price will be £200.

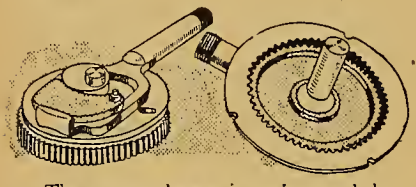


A newly designed three-wheeler with shaft transmission.

The "Best" Mechanical Lubricator.

Slow-speed Pump: Minimum Number of Working Parts: Interconnected with Hand Pump and Visible Drip-feed.

ALREADY some of our leading machines are being fitted with oil-circulating systems driven by the engine, while innumerable devices calculated to perform the same duties are being designed or are in the experimental state. Among these is a simple device which will shortly be placed on the market by Best and Lloyd, Ltd., of Handsworth, Birmingham.



The pump plunger is reciprocated by the eccentric which revolves in enlarged eye of the connecting rod. The wedge (shaded) is used to vary the stroke. Great speed reduction is obtained with this form of gearing.

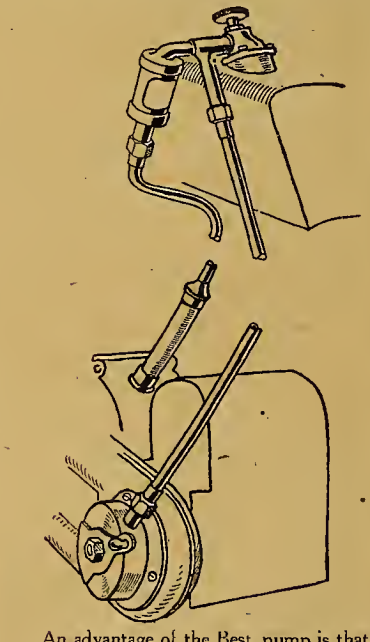
The Best mechanical oil pump has the great merit of simplicity, for it consists of but ten parts, which are readily dismantled or assembled, since there are no screws or valves in the construction. It is designed to work in conjunction with either the existing type of drip-feed oil pump or one of a simplified pattern specially made for the purpose; in either case the suction and delivery valves in the drip-feed are utilised for the mechanical pump. With this system the hand-pump is always available for the delivery of a full charge, while, as the whole of the oil passes through the drip-feed sight glass, in the unlikely event of a failure of the pump, the cessation of the oil flow would be readily discernible.

Most engine-operated oil pumps suffer from the fact that they work at too great a speed, and, in consequence, the bore and stroke are so small that the action may be easily deranged in cold weather owing to the viscosity of the thick oil necessary in air-cooled engines. In order to overcome this defect, a special reduction gear has been incorporated in the Best pump, which enables the pump to work very slowly and so permits the employment of a large bore and stroke.

A neat sight feed lubricator designed to work in conjunction with the Best mechanical pump.

Simplicity, compactness, and great speed reduction are the essential characteristics of this gear, which operates in the following manner. A spindle, suitably driven from one of the engine timing wheel shafts, rotates within the case of the pump driving gear. On this spindle is an eccentric which fits in the central hole of a bronze wheel having fifty-nine teeth on its periphery, and this wheel meshes with a ring fixed on the back plate of the case and having sixty internally-cut teeth. Rotation of the eccentric causes the bronze wheel to roll round inside the ring, making one revolution to sixty of the spindle. From the wheel a steel peg projects, and this drives a brass disc having another eccentric integral with it and moving within the enlarged end of the pump connecting rod.

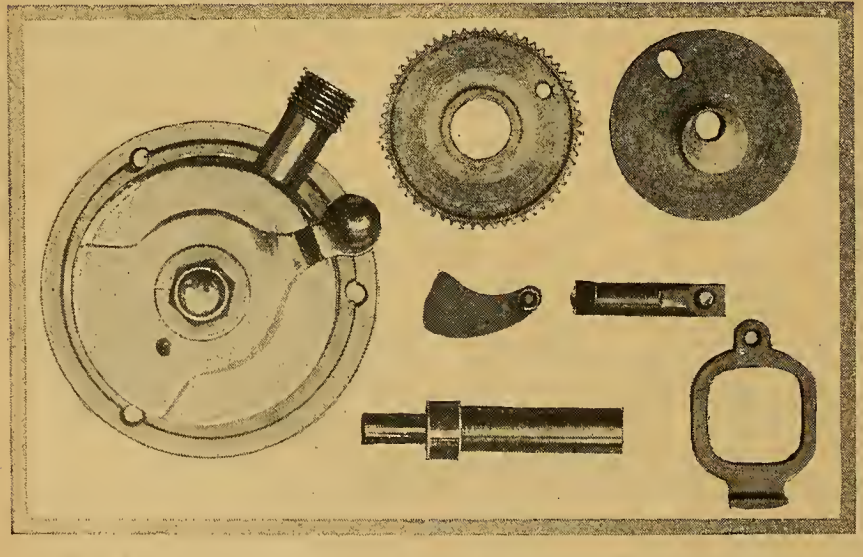
On the outer cover of the case is a movable plate carrying a wedge which can be moved in between the eccentric and a turned-up lip on the connecting rod; in this position a full stroke of the pump is obtained at each revolution of the eccentric, but, if the wedge is moved to the "minimum" position, the eccentric rotates idly and no motion is imparted.



An advantage of the Best pump is that it can be easily fitted to any machine equipped with a Best and Lloyd semi-automatic drip feed. The diagram shows the manner of application to a 1913 Triumph.

It will be seen that by this device the pump makes one stroke to every 120 engine revolutions, so that all the objections which can be raised to the small high-speed pump are eliminated.

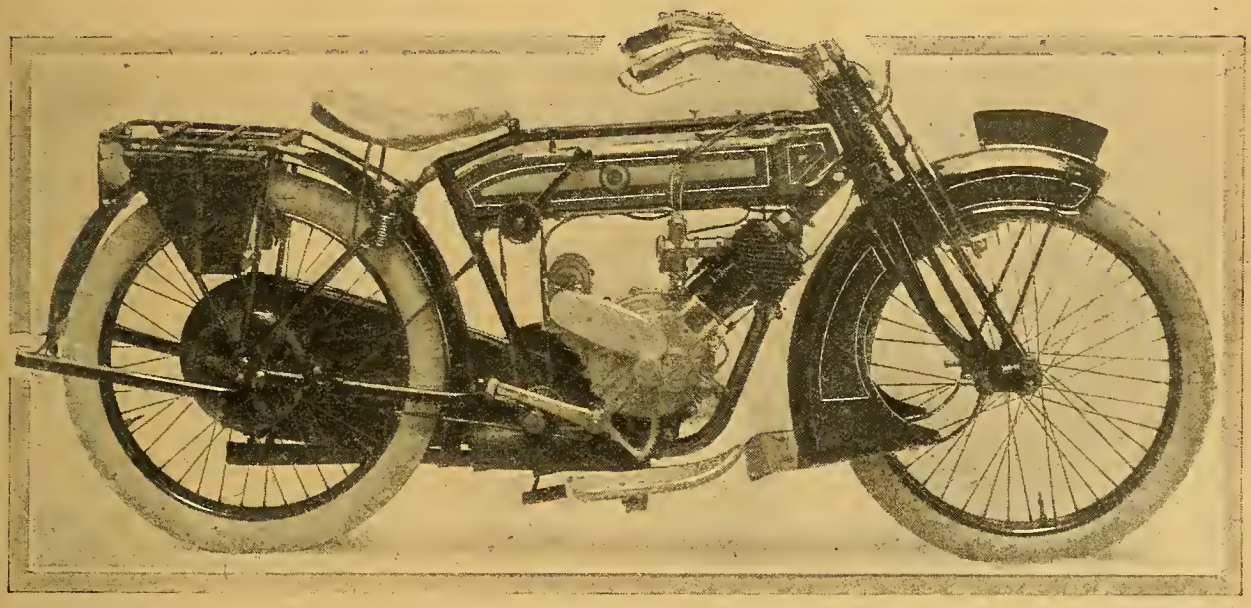
In the case of machines already fitted with the Best and Lloyd semi-automatic drip-feed, the mechanical oil pump may be fitted with a minimum of trouble, the work being quite within the powers of any good cycle mechanic. We inspected one fitted to an early pattern Triumph, and this was driven from the magneto sprocket nut, which had a square hole at its outer end, engaging with a square spigot on the driving spindle of the pump. The case was fitted to the magneto chain cover by three small screws.



(Left) The Best oil pump complete. (Right) The internal parts, which are few and simple.

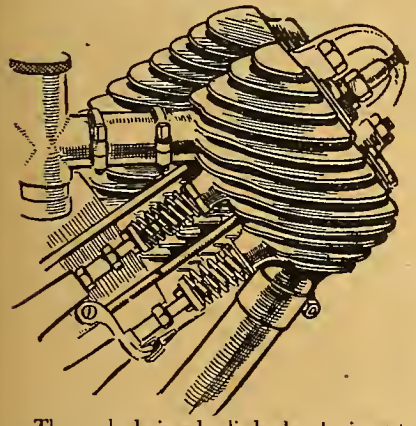
The 1920 3½ h.p. P. and M.

Improved Cylinder Design, Mechanical Lubrication, Hand and Foot Control to Rear Brake, Strengthened Starter Mechanism.



Mechanical oil pump driven from timing gear, a redesigned cylinder with cooling flanges parallel with ground line, and an improved kick-starter are obvious improvements noticeable in this model.

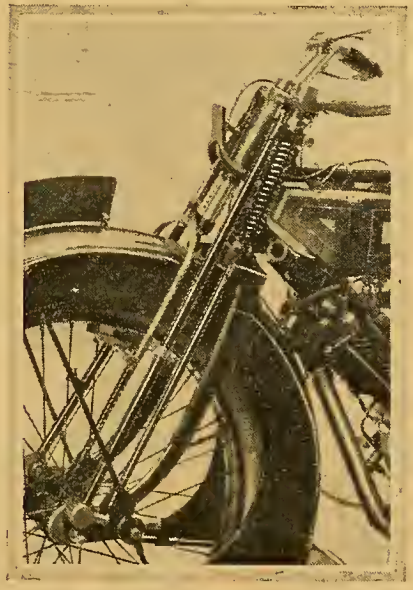
SOME important alterations have been made in the popular P. and M. since we last saw the Six Days Trial model in the company's showrooms at Berners Street, London, W.1, some few weeks ago. The most conspicuous improvement has been in the engine. The bore and stroke remain the same, namely 84.5×88.9 mm. (498 c.c.), but the cylinder has been completely redesigned. It



The newly designed cylinder has horizontal radiating flanges.

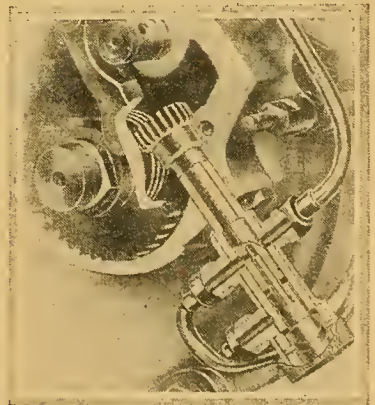
is a very fine casting, and the fins are now parallel with the ground, and there is a large air space between the valve chamber and cylinder; the ports have now a streamline form, and the valves have been enlarged.

The lubrication is effected by means of a mechanical pump, driven at low speed by a worm on the exhaust cam wheel, and oil is delivered alternately to the big end and to the cylinder. The



P. & M. front forks which have been greatly strengthened. Large screw-down greasers are fitted to all bearings.

rotating portion of the pump is in two parts, and, of these, the one to which the pinion is attached has a spigot at its further end; it is also drilled to form the bore in which the plunger works; connecting with the central hole is a smaller one at right-angles, which registers with the various suction and delivery passages as it rotates. The spigot referred to engages with a slot in the upper portion of the pump, which also carries the plunger; and the upper portion is encircled by two annular cams, form-



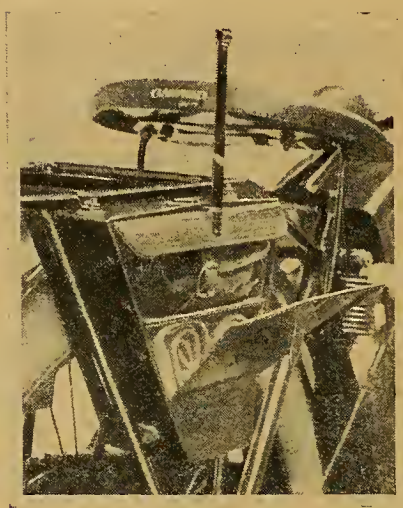
The mechanical oil pump of the 1920 P. & M.

ing a groove into which two pins protrude. These pins are held diametrically opposite to one another in a fixed cap at the head of the pump. The rotary motion conveyed by the spigoted section results in a reciprocating motion being given to the plunger-carrying portion through the agency of the groove in the head as the cams ride on the fixed pins. The pump

is driven at one-fortieth of the engine speed, and, on removing the cap at the head, a small screw is revealed above the cams, by means of which the throw of the plunger may be altered if desired. According as the hole at right angles to the pump bore registers with the outlets, oil is either drawn in or expelled. In the position shown in the photograph the plunger is at the bottom of its stroke, and the oil is being expelled into the lower of the two outlets, which leads to the big end. A further movement will bring the hole into a horizontal position. In this position it communicates with one of two channels diametrically opposite to each other in the outer casing. At this moment the plunger is at the top of its stroke, and oil is drawn in from the inlet and through one of the channels, and on the down stroke is expelled into the upper of the two outlets as soon as the hole registers with it. A further movement brings the hole opposite the other groove in the pump casing, a further charge of oil is drawn in, and thus the cycle of operation is continued.

The oil lead to the big end passes through the crankshaft boss, and almost touches the flywheel, on which a scroll is cut, and the end of this terminates in a hole leading to the hollow crankshaft. The stream of oil impinging on the flywheel is led by centrifugal force along the scroll right into the big end bearing. A hand-controlled oil pump is connected directly to the crank chamber.

Another important feature is the kick starter, which has been somewhat simplified in design. It works directly on the crankshaft, and its pinion is neatly enclosed by a cover forming part of the magneto chain case casting.



Spacious tool-bags are a commendable feature on the new P. & M.

We have already referred in these pages to the ratchet brake with which the latest model P. and M. is fitted. This is now interconnected with the band brake on the rear wheel, so that this brake may be actuated either by the hand or the foot. A movement of the pedal does not alter the hand lever in the slightest degree, owing to the ingenious arrangement of the control rods. A rim brake is fitted to the front wheel.

The remainder of the machine does not show any startling features in design, and the improvements are chiefly in detail. A larger transmission shock absorber is now fitted, and the design of the spring forks has been considerably simplified. The excellent carrier now has welded joints, and on each side of it are spacious tool bags, which are securely closed by a strip steel bolt in place of the usual leather straps.

We have an interesting announcement to make concerning Messrs. Phelon and Moore, Ltd. Hitherto the firm have adhered strictly to reliability trials, since their machine, while capable of maintaining a good average, was noted rather for its excellent finish, its unimpeachable reliability, and its steady going, than for its achievements as a speed mount. However, this state of affairs is now ended, and next year the firm intend to have a sporting try at the 1920 Tourist Trophy Race, and, in consequence, we hasten to wish them the success they most thoroughly deserve.

A New Long-stroke Single.

The Corona Junior Motor Cycle with 4 h.p. Engine of 448 c.c.

AN interesting new machine which will be exhibited at Olympia is the Corona Junior, which has been but recently designed and is now being manufactured in large quantities by the Meteor Manufacturing Co., Ltd., of Tollington Park, London, N.

One of the principal features of this machine is that the number of parts employed is claimed to be less than on any other machine.

The 4 h.p. four-stroke engine, which has a bore and stroke of 72×110 mm., has its cylinder cast integral with the crank case, and has a detachable combustion head. This is constructed of a special alloy which has a high conductivity, and permits the decarbonisation of the piston and cylinder head whilst the engine is in the frame. The crankshaft is a one-piece steel stamping and is offset from the centre line of the cylinder, which, the makers claim, reduces wear and side strain on the cylinder walls.

Totally enclosed valves, fitted with adjustable tappets, are employed, and are operated directly from the cams machined integral with the timing wheel and magneto chain sprocket, thereby dispensing with the use of rocker arms, and self-aligning ball bearings are used for the main bearings. Automatic lubrication has been incorporated, a constant level of oil being maintained by means of a mechanical pump. A single-lever carburetter is provided, and a welded steel silencer of novel design, which can be rapidly dismantled by removing one bolt.

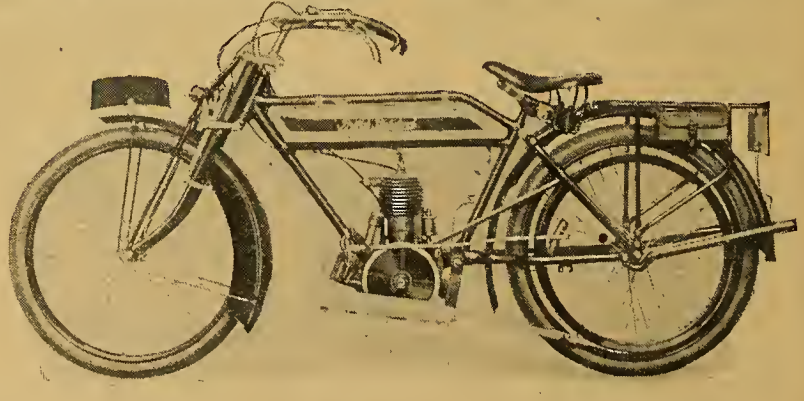
Knock-out spindles are fitted to both wheels, the rear one of which carries the totally enclosed internal expanding brake. A noteworthy feature of the Corona Junior is the method of springing the front wheel, the mechanism being enclosed.

Three models will be standardised, a light solo mount with fixed belt drive, a similar machine fitted with a two-speed countershaft gear box, and a third model, designed for sidecar work, which will be equipped with a three-speed gear and an enclosed clutch and kick-starter.

It is extremely illuminating to note the interest being taken in the single-cylinder; would-be prophets would have us believe that the end of the single-cylinder is in sight, but still it holds a high position as the most economical machine at a moderate price, in spite of the desirability of multi-cylinder engines for luxurious mounts.

Direct to the Public.

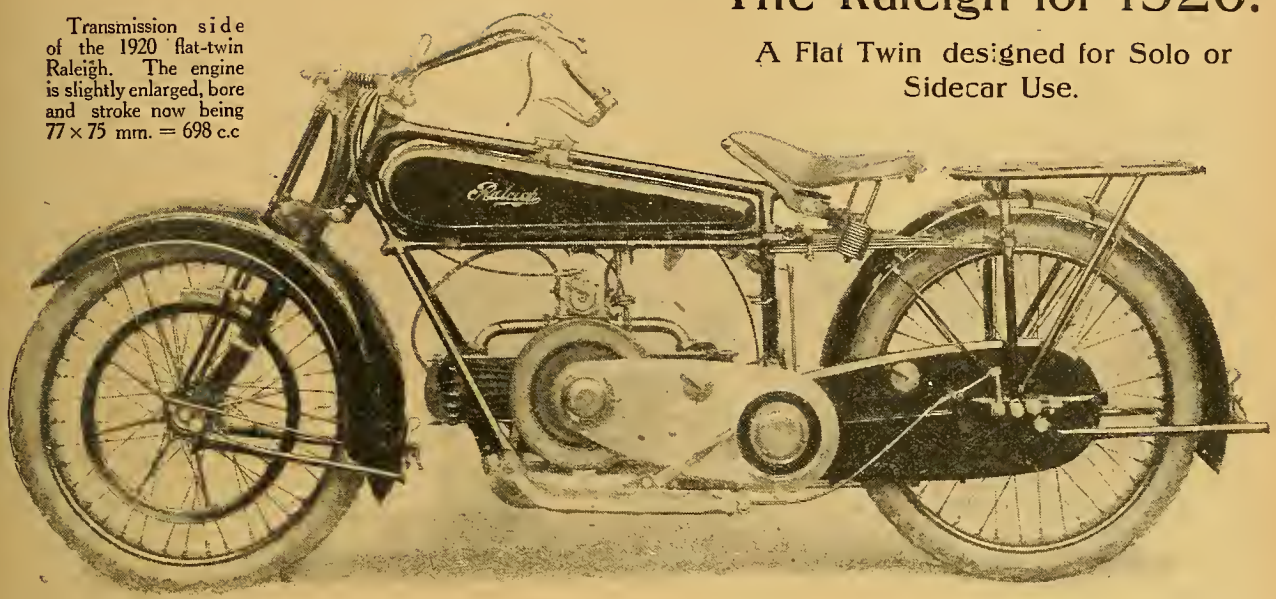
A lightweight which is to be marketed direct to the public is illustrated. The engine is a 2¾ h.p. two-stroke, and the equipment includes Saxon or Brampton forks, 26×2in. Palmer tyres, and aluminium footboards. The price, £43, includes lamps and generator. The makers are British Standard Motors, 145, Lichfield Road, Aston, Birmingham.



The British Standard, a new lightweight which will be sold direct to the public.

The Raleigh for 1920.

A Flat Twin designed for Solo or Sidecar Use.

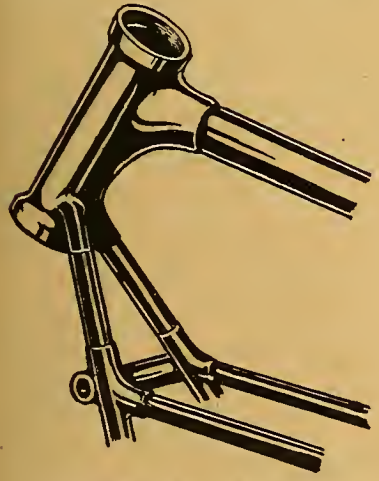


Transmission side of the 1920 flat-twin Raleigh. The engine is slightly enlarged, bore and stroke now being 77 × 75 mm. = 698 c.c

SINCE we first described the flat twin Raleigh in May, 1918, there have been many detail improvements. Every little point has been carefully considered until the machine is well-nigh perfect.

The engine remains much as before, but the dimensions have been increased from 77×70 mm. to 77×75 mm. bore and stroke, giving a capacity of close on 700 c.c., which means a little more power for sidecar work.

Roller bearings are used throughout, and a specially built-up crankshaft



The Raleigh head lug and sidecar connections.

enables the cylinders to be very nearly in line without off-setting the connecting rods; moreover, the balance weights provided, combined with the very small offset of the cylinders, have the effect of practically banishing the small horizontal couple, which can only be entirely removed by making a three-throw crankshaft and using two light connecting rods to one cylinder, balanced by a heavier one to the other; this method does not wear well, and, where tried, has been abandoned.

Detachable cylinder heads are fitted, and these can be very quickly removed, for, on loosening a gland nut, the inlet pipe comes away with the head, and the exhaust pipe is so fitted that when its union nut is removed it does not impede the removal of the head; also it is gas-tight in any position which the union nut allows it to take up.

A very effective shock-absorber is fitted to the engine-shaft, consisting of rounded projections on one part resting in depressions of a greater radius in the other. This gives an easy movement at first with a greatly increasing resistance as the spring is compressed. It is entirely automatic in action and cannot slip. The flywheel is loaded with lead.

The silencer, which also forms the underscreen, is provided with internal passages from each cylinder meeting in the centre and giving an inductor effect, the flow in each pipe being aided by that in its fellow.

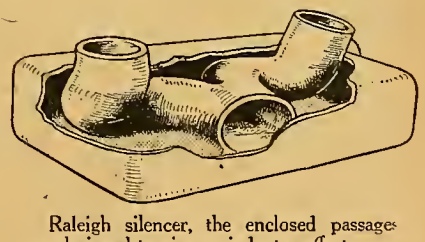
As before, each valve is provided with two springs, whose period of vibration differs, the object of this being to stop bouncing.

Warming the Gas.

The induction of the charge still takes place through the timing case, a Raleigh feature which has been much copied, and a space is left below the magneto platform and above the crank case. This has the effect of improving the cooling of the front cylinder by allowing the stream of air, which is closing in after being disturbed by the front mudguard, a free passage over the cylinder, not interrupted by a solid erection on the crank case. An Amac carburetter (with either one or two levers) is bolted by means of a flange on the cover of the timing case, and is quite out of the way of the rider's foot or leg, which is not always the case on a flat twin.

Lubrication.

Oil is fed by a suction drip feed to a point in the crank case above the front connecting rod; this ensures the front cylinder getting its full supply of oil. The suction in the crank case is made very effective by the rotary release valve, which consists of ports cut in the shaft driving the magneto. Consequently, there is no possibility of a failure in the oil supply. This also has the advantage of allowing the warm air from the crank case to circulate around the inlet passage through the timing case, and warm the gas as soon as it reaches the engine.



Raleigh silencer, the enclosed passages are designed to give an inductor effect.

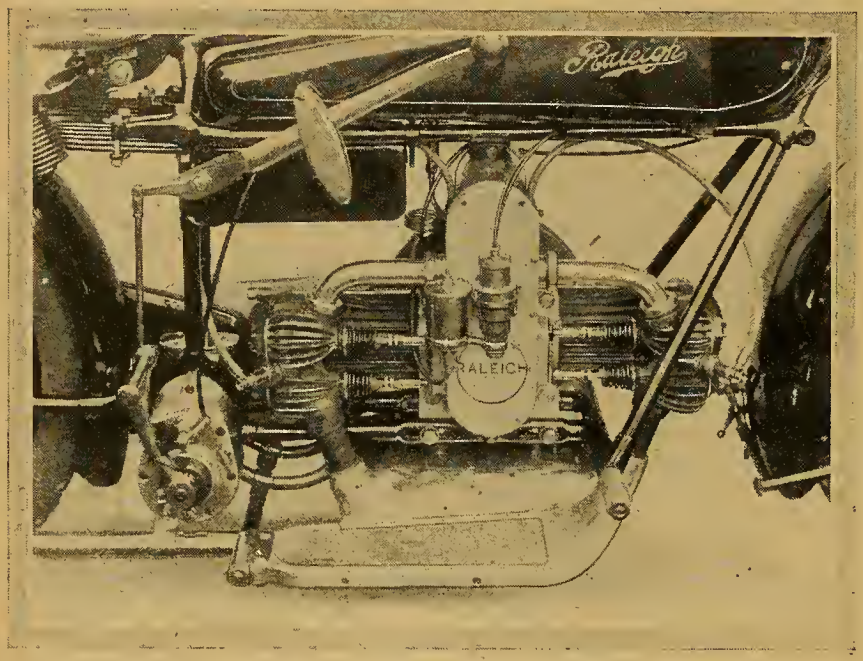
A hand pump is also provided, by which an extra supply of oil may be given as occasion requires—for instance, in stiff climbing with a sidecar attached.

Gear Box and Chain Adjustment.

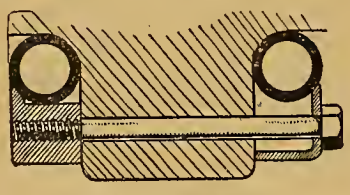
A new gear box has been specially designed for this model; it is housed in a casing which is built up in the frame—consequently, it is absolutely rigid, and cannot get out of line. These are very great advantages, but they necessitate shifting the engine in the frame for chain adjustment purposes. This is, however, accomplished in a very simple and satisfactory manner. An extension of the crank case projects downwards between the twin tubes below the engine; on each side of this are

New Models.—

placed angle pieces, about six inches in length, and two bolts secure the whole. As the bolts are screwed home, the angle pieces meeting the curved sides of the tubes pull the engine downwards and hold it tightly. There is, moreover, a third attachment below the tank. The rear chain is adjusted as usual at the rear hub, and this can be done without disturbing or affecting the operation of the brake, which is of the internal expanding type, working within the rear sprocket. The clutch contains two plates, having cork inserts gripped between three plain plates, and the plate containing the driven sprocket is mounted on ball bearings. Both the main and layshafts of the gear are short, and of ample diameter, and, in consequence, are very stiff; the layshaft is geared down, and runs at low speed; this has the effect of reducing the loss of efficiency due to oil churning. Another point is that the sleeve carrying the driving sprocket is longer than usual, and takes a bearing on the main shaft at each end, with an oil chamber between. An enclosed kick-starter is provided.



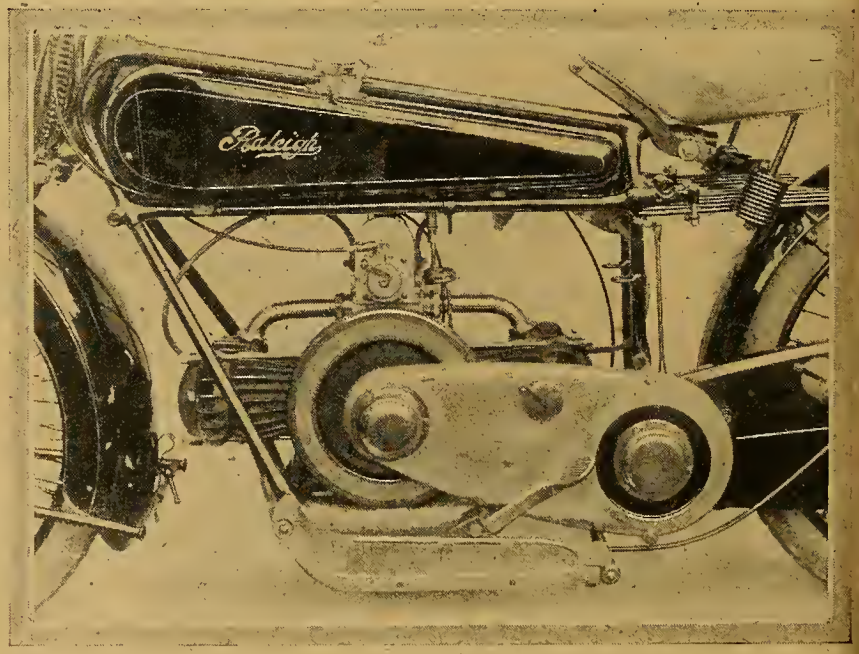
Valve side of the Raleigh flat-twin. Note that the gear box is built into the frame, and that the silencer forms an underscreen.



Method of securing engine to the lower twin tubes

The spring frame has been found to be so satisfactory that no alterations have been necessary. The construction of the gear box enables the joint of the sprung rear portion to be very close to the centre of the drive. The lower joints work on hardened steel bushes, those at the end of the springs on phosphor bronze.

With the exception of the top tube and head, the whole frame is duplex; this gives great strength and light



Transmission side of the Raleigh power unit. The light portion of the flywheel is a lead insertion weight, the actual weight of the complete machine is 280 lb.

Both chains are enclosed; the inside part of the front case is of cast aluminium, and is provided with a groove around the countershaft opening, in which the rear case (sheet steel) can rock as the spring frame comes into operation. This is made oiltight by means of a felt washer. Both mudguards are of ample dimensions, that in front being extra wide and, extending beyond the forks, is packed where the forks pass through to prevent mud from this point spattering the machine and rider. The footboards are of wood, mounted in aluminium frames and rubber-covered. The rear brake is operated by the left heel, the front by the usual handle-bar lever. The brake rim in which the front brake acts is spoked, and attached to the hub in the same manner as the rear sprocket; thus, the wheels, as well as being quickly detachable, are interchangeable.

Detail Refinements.

Another important point, often neglected, is that an oiler is fitted through which lubrication can be supplied to the head bearings, both top and bottom.

The toolbox is situated below the tank in rear of the magneto, and is thus on the sprung part of the machine.

Other refinements consist of taking the operating wires partly through the handle-bars, handle-bar operation for the clutch, and an extension of the handle-bar stem to carry the head light. The stands are secured by spring washers to prevent rattling.

The Raleigh is designed both for solo and sidecar use, and should be most satisfactory for either. The riding position is delightfully comfortable and the saddle low. The sidecar is attached at four points to the main frame; in addition, a triangular member carrying the side-car wheel, which is sprung in the same manner as the bicycle, is attached at the top and bottom of the loop over the rear wheel.

The Stanger V Twin Two-stroke.

A New Engine Unit which will be Exhibited at the Olympia Show.

THERE have been several V twin two-strokes designed and made, but, for reasons known only to their sponsors, they have not been placed upon the market. Among the exhibits at Olympia, however, a new 5 h.p. two-stroke engine will be staged by the Trotman Patent Dandy Co., a firm of paper makers' engineers at Wood Green, London.

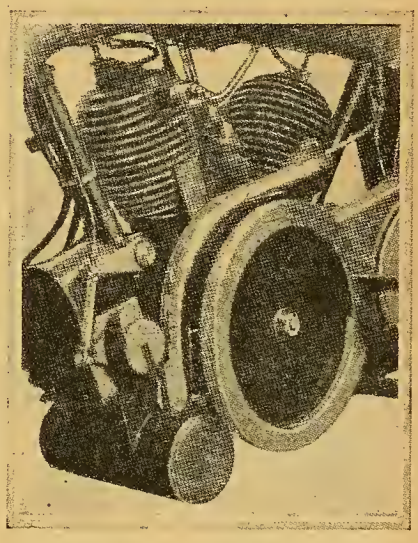
Designed by an engineer, whose experience with motor cycle engines goes back to the year 1897, when he designed and constructed the 2¾ h.p. Stanger quad, the engine under review is of the conventional three-port type, and can be fitted in any motor cycle frame which accommodates present-day engines. It consists of two cast iron cylinders with large radiating fins. Mounted in a staggered position on an aluminium crank case, and set at an angle of 45°, compression relief valves are situated in the usual hexagon housings and recessed and drilled from all sides of the hexagon, thus affording a very quick relief of compression. The entire interiors of the cylinders are machined, leaving the heads perfectly smooth, and tending to keep them free from carbon deposit. Cast iron pistons, of the deflector type, are used, and are fitted with three rings—two in the top and one in the skirt.

The gudgeon pins (which are hollow) are a light driving fit in the piston, and are fixed in a rather novel manner. One end has a fixed pin projecting about ⅛in. on either side of its diameter. When the pin is driven home a split pin is pushed through a hole and opened in the bore of the gudgeon pin.

A one-piece two-throw crankshaft of 50 ton steel (case hardened) is employed, set at 180°, and is very short and stiff between the throws.

The crank case, which is of aluminium, is divided laterally, and by a dividing wall, which forms two separate chambers. The centre bosses are machined to take a large compression retaining bush. The outer bosses are fitted with self-aligning double ball bearings, and also compression retaining bushes, so it will be seen that each throw revolves in a complete crank chamber of its own.

Steel connecting rods, with a phosphor-bronze small end bush, are fitted, the large end being case hardened and ground, and so shaped as to thread over the solid crankshaft. The rollers are slipped through a small groove at the highest point of the crank web, two halves of a hardened steel washer having first been placed in the connecting rod. When the full number of rollers are in position the other split washer is fixed with the two split pins. Hardened washers assist to keep the roller in a true path on the crank pin.



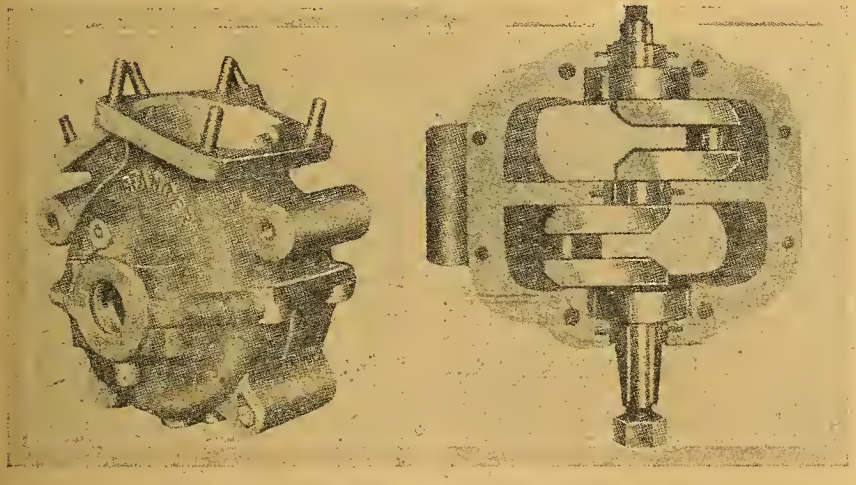
Flywheel side of the Stanger two-stroke engine, a twin of 5 h.p., having five working parts.

Lubrication is effected by means of a twin drip feed, which is carried to the lowest point of the inlet ports. Although drip feed is fitted, the designers advise the use of the petroil system.

The magneto is situated on a platform in front of the engine, and is driven by a chain encased in a complete dustproof aluminium case.

A very large flywheel is employed, to which is keyed the driving sprocket.

A feature of this engine is that it may be adapted to almost any type of motor cycle frame.



Exterior and internal views of the Stanger twin two-stroke engine.

The Olympia Car Show.

Many Exhibits of Interest to Motor Cyclists.

ONE of the effects of including the lighter four-wheelers in the Olympia Automobile Show was that quite large numbers of motor cyclists attended the exhibition. A quantity of motor cycles were to be seen in the immediate precincts, the owners obviously being intent on the examination of little cars. It is difficult to draw the line between four-wheeled motor cycles and cars, but such machines as the G.N., which, though a smart miniature car in appearance, has a distinctive transmission of its own, and sells at a price competing with high-class sidecars, is obviously of interest. The C.A.R., with its three-cylinder air-cooled radial engine, is perhaps rather a large proposition to be included in the list, but its low price makes it well worthy of mention. The Little Midland, Grahame-White Buckboard, Tamplin (on view outside the Show), and a few others are well in the motor cycle class, and attracted much attention. Many of the accessory exhibits contained much of interest to motor cyclists, and the number of well-known carburetter manufacturers, who are specialising in single-lever instruments for use on motor cycles, throws an interesting light on the trend of events. These descriptions of the various exhibits will be found in *The Autocar* issues of November 8th and 15th, and the enormous crowds of spectators were sufficient evidence of public interest. It is often hardly possible to get a clear view of the most attractive vehicles, and it takes a very appreciable time to walk down the busy aisles, even if none of the stands are examined *en route*. From these facts a happy augury may be drawn for the success of the Motor Cycle Show.

The 1920 Senspray Carburetter.

Sensitive or Automatic at will; Two Lever Control; Cast Aluminium Body; Greater Accessibility.

LATTERLY the name Senspray has been rather less to the fore than it was wont to be, for in pre-war competition circles it was almost impossible to witness an event in which this famous carburetter was not fitted to some of the most successful machines.

The makers, Charles H. Pugh, Ltd., of Tilton Road, Birmingham, have not been idle, however, and a tour of their works at once indicates the reason for their absence from the motor cycle world during the past season. On every hand, in their extensive shops, one sees huge stores of giant aeroplane carburetters, and it is owing to the Government's requirements in this direction not yet being filled that the manufacture of motor cycle instrnments still remains in abeyance.

A new type has been evolved, however, and early in 1920 it is expected that it will be placed upon the market, and a short test on a machine fitted with one of the first examples demonstrated the fact that it has many desirable features.

The general principle is the same as that formerly employed, but the body is now an aluminium die casting, and has end-plates of the same material. These are held on by flat springs of the same type as those used on magneto contact-breaker covers, and they contain bronze bushes for the throttle spindle.

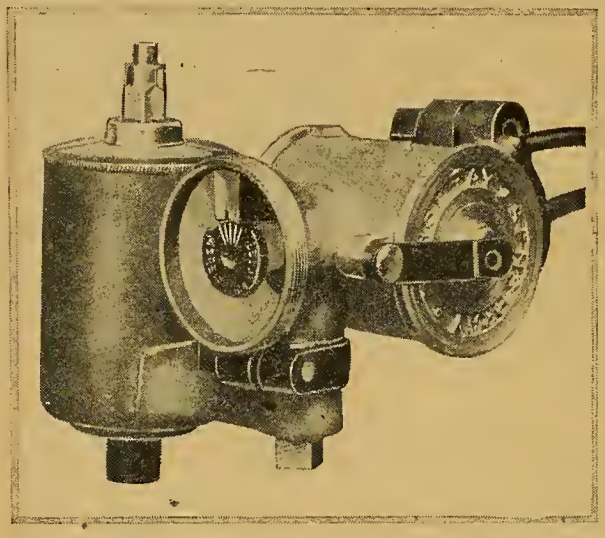
In the old Senspray carburetters, the action was practically automatic, and, if tuned for maximum power and speed, the petrol consumption was rather high at low speeds. The present type, by a very ingenious modification, can be made sensitive, semi or fully-automatic at will, accordingly as the rider prefers full automaticity (one lever control) or maximum fuel economy (involving use of extra air lever when picking up or climbing).

This result is achieved by mounting the small vaporising cone so as to be rotatable in its housing and by drilling a hole in it, corresponding with one in the carburetter body, and communicating with the outer air; the hole is on the engine side of the jet. By rotating the vaporiser, the hole is brought more or less into register with the one in the housing so that the depression (so-called "vacuum") may be varied at will, and with it the suction on the jet.

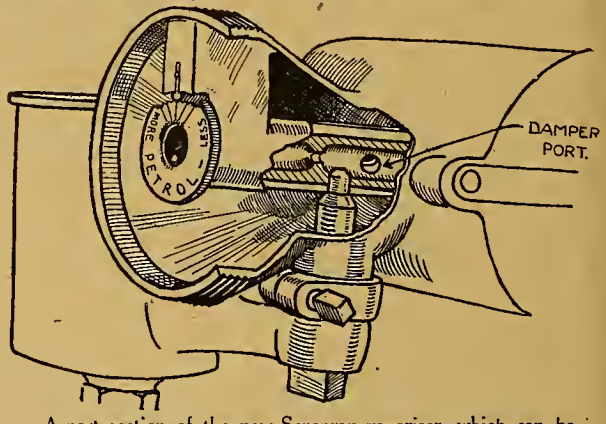
A diagram, which illustrates these notes, clearly shows the manner in which the vaporiser is operated. We were informed that, between the extreme settings, when used on a standard 85×88 mm. engine, the consumption varied from about 90 m.p.g. to 107 m.p.g.

In practice, we found that with the vaporiser damping ports fully open the setting was not so sensitive as to render the machine likely to conk out if the mixture were bungled; but a judicious manipulation of the air lever was needed when ascending hills or picking up at low speeds; with the vaporiser turned to the extreme "more petrol" position, the action was fully automatic, the air lever being only used when starting up.

A detail improvement which prevents incorrect assembly is the turning of a groove round the jet carrying portion projecting from the float chamber; the carburetter body clip bolt fits into this.



The new Senspray carburetter, which has a cast aluminium body with readily detachable end caps. A vertical model is made to suit certain V and horizontal twins.

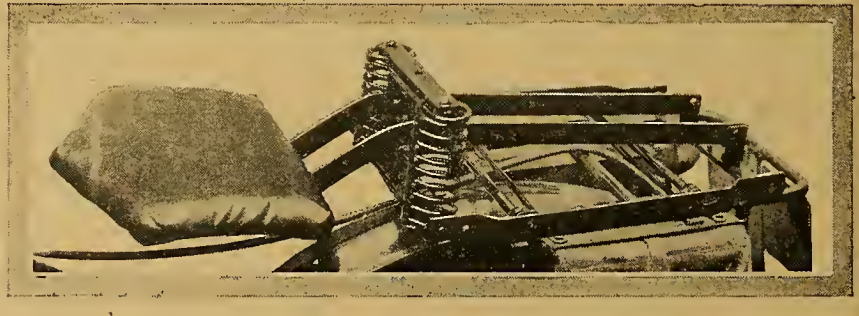


A part section of the new Senspray vaporiser, which can be rotated, thus opening a damper port which decreases the suction on the jet, and makes the carburetter sensitive to the air control

A Tan Sad Seat for the Driver.

A Sprung Seat for Motor Cycles combined with a Pillion

THAT over 15,000 Tan Sad pillion seats have been sold during the present year is sufficient proof of their popularity, and, *apropos* the discussion regarding the danger of pillion riding, the principals of the Tan Sad works advise us that they have yet to hear of the first accident where one of their sprung seats has been used. Fifteen thousand private buyers of an auxiliary fitment in less than a year probably constitutes a record, and, to those who know the rapid growth of the Tan Sad Works, their success appears as quite a romance.



A novel form of saddle springing introduced by the Tan Sad Works

New Models.

Up to the present Tan Sad specialities have consisted of a main unit—the pillion seat—to which other units may be fixed without trouble in order to render it suitable for various purposes, and the 1919 model completely covered the requirements of the motor cyclist who needed a sprung platform on the carrier for carrying a passenger, a parcel, a tin of petrol, etc. For 1920, the pillion seat has undergone several improvements, including an upholstered top in place of the loose cushion, and the springs are shorter, which makes the seat much neater, and a combined rear lamp and rear number-plate have been added to the range. This is referred to elsewhere in this issue. Detail improvements will be found in most of the units.

Probably the most interesting addition, however, is the new spring seat for the driver. This is illustrated on the previous page, and it will be seen that it attacks the proposition from a new point, a seat being carried on the forward ends of two levers which are anchored to the rear part of the carrier and are supported by coil springs about midway, *i.e.*, to the rear of the seat, which follows the lines of a chair seat rather than a saddle. The photograph reproduced shows one of the several forms of seat with which experiments have been made, but in all probability a different shape will be adopted in the final model shown at Olympia.

A Comfort Giving Device.

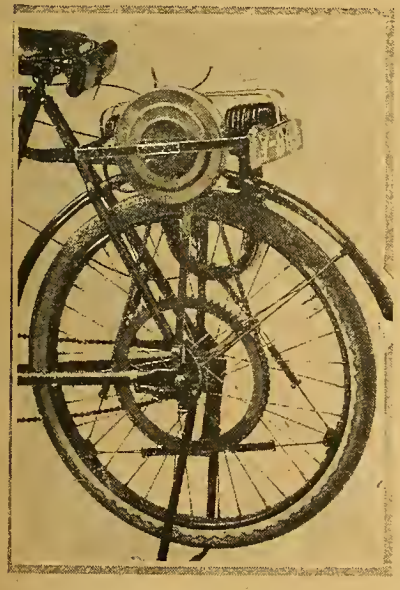
The principle of the springing needs no explanation, this point being sufficiently clear in the illustration, but it is necessary to point out that a second unit can be fitted to the seat, in the form of a pillion seat, which utilises the same springs at the front as support the driver's seat, and has springs of its own at the rear. If the space at the rear is to be used as a carrier, then an alternative unit is provided, thus giving the motor cyclist a sprung platform. As this fitment is a seat instead of a saddle, Mr. F. H. Headley, the designer and principal of the firm, affirms that greater comfort is provided. Apparently he has made a close study of the question of riding comfort from an anatomical standpoint, and disagrees with the conventional form of saddle, which, he claims, is but a development of the horse saddle, which was originally designed primarily to fit the anatomy of the horse, that of the rider being a secondary matter, and, at best, only a compromise.

From a short road test on a solo machine over terribly pot-holed roads, we formed the opinion that the new driver's seat would become as popular as the 1919 Tan Sad pillion. It was extremely comfortable, and created a new sensation unlike that associated with a spring frame or an ordinary saddle. We hope shortly to fit one of these seats to a motor cycle in daily use, and in due course we shall record our impressions.

The Motorised Bicycle.

The Johnson Motor Wheel. A Horizontally-opposed Two-stroke Attachment for Pedal Cycles.

THE Johnson motor wheel is another of the many ingenious attachments which have been brought out to motorise the pedal cycle, and is one of the most practical we have seen. The



Flywheel side of the Johnson motor wheel The loose wire above the flywheel leads the current to the lamps.

outfit consists of a special wheel, a stand, and a motor unit with tank and controls. To fit a pedal cycle with this device merely necessitates the removal of the existing wheel, the insertion of the special wheel, and the attachment of the stand and power unit. The wheel is rather stronger in construction than the ordinary one, and is provided with a sprocket loosely mounted on to the hub, the drive being taken through springs anchored to brackets riveted on the wheel rim. The whole outfit, it is claimed, can be fitted to a pedal cycle in the space of one hour.

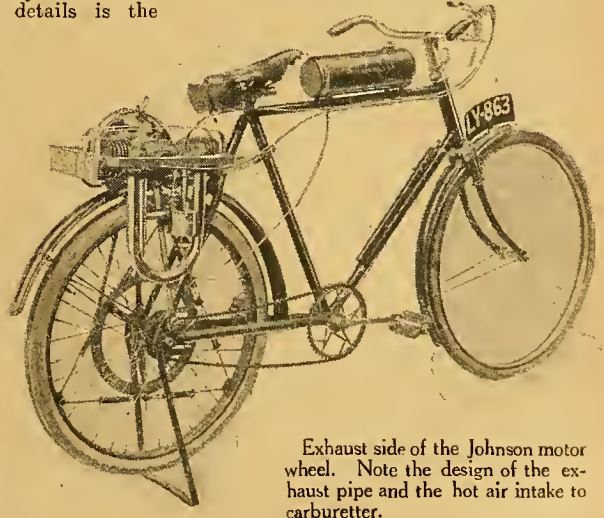
Fixed above the rear mudguard, the engine unit is quite central and equally balanced; that is to say, the engine is not on one side. It is mounted on its own frame or carrier, which is clipped round the saddle tube and supported by stays running from each side of the motor carrier to the plate carrying the stand and the special wheel.

Easily Fitted.

The only alteration necessary to the cycle is the cutting of a piece out of the mudguard so as to allow sufficient clearance for the transmission chain.

A two-stroke flat twin is the power unit, lubricated on the petroil system. One of the most interesting details is the magneto, which is built into the flywheel and works on practically the same principle as the Ford magneto. The flywheel contains the magneto pole pieces and cam, while the stationary portion, which is called the armature plate, holds a large ignition coil and armature, a smaller lighting coil and armature, the condenser in a metal tube, and the contact-breaker. From the magneto there run two wires to the plugs and a thinner wire for illuminating the head and tail lamps. The current is obtained for both ignition and lighting by rotating the magnets round the coils and their armatures; at the moment of maximum intensity, the cam in the flywheel opens the points of the contact breaker, causing a strong ignition spark at the plugs. Variable ignition is obtained by moving the stationary part of the magneto.

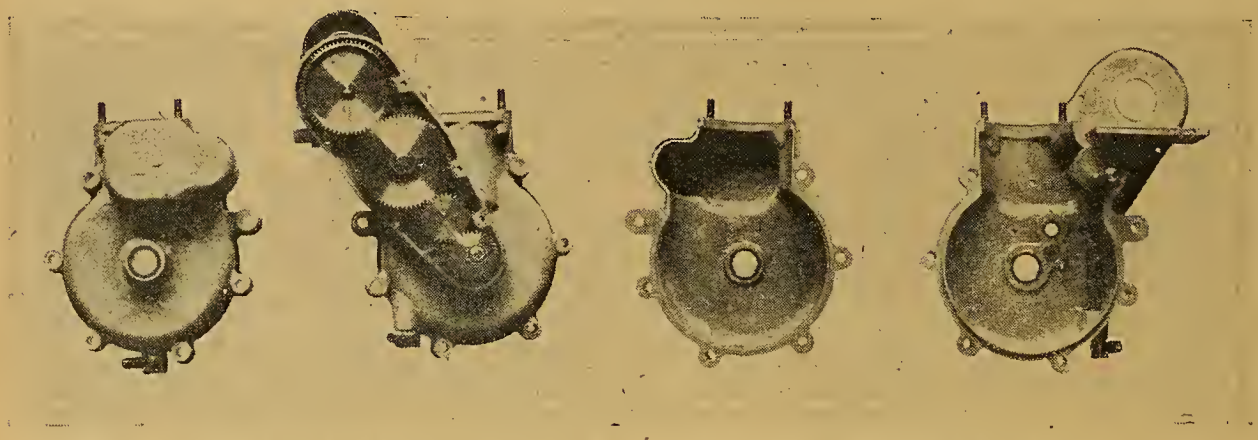
A simple form of automatic carburetter is fitted, which is provided with an exhaust muff so that sufficient heat is obtained to vaporise the fuel in the coldest weather. The throttle lever controls not only the throttle and air, but also opens the compression relief valve in the engine. Since the Johnson motor wheel has a coaster brake of its own, together with the existing brake on the bicycle, it conforms with British regulations. We have not yet had an opportunity of trying the outfit, but hope to do so shortly. It is handled in this country by the British Johnson Motor Wheel, Ltd., 127, Oxford Street, London, W.1.



Exhaust side of the Johnson motor wheel. Note the design of the exhaust pipe and the hot air intake to carburetter.

A Sleeve Valve Motor Cycle Engine.

A Four-stroke from which the Poppet Valve is Eliminated, produced by Messrs. Barr and Stroud.



The two halves of the crank case, showing interior and exterior. Note the train of wheels for sleeve and magneto drive.

IT has long been a source of wonder to motor cyclists that the sleeve valve engine has not been adapted to motor bicycles. In the motor car world, the Daimler, Panhard, and Minerva cars are fitted with sleeve valve engines made under the Knight patents, their licences to manufacture dating from ten years back, while the famous car of Swiss make, the Piccard Pictet, has a somewhat similar engine made under a British patent. Yet up to the present time little has been heard of an engine of this pattern being made of a size and type suitable for the popular little vehicle in which this journal is especially interested. It may be argued that the poppet valve engine universally fitted to motor cycles is so satisfactory that nothing better is required. That it possesses reliability, keeps cool, maintains and gives off its power, is an argument which may be put forward by many. Yet there *is* something wanting, something we have advocated for years, and that is silence. To silence the exhaust is not difficult, but to render innocuous the rattle and din proceeding from valves, cams, and timing wheels is not easy without interfering with the efficiency of the engine. We want rapid valve opening, rapid closing, large valves, and a fairly high lift so as to get the utmost out of our small engines, and to get all these we have to put up with a certain amount of noise. Such noises are more wearing to the nerves on a long run than the regular patter of the exhaust. The solo rider suffers from the complaint, and the passenger in the sidecar fares worse, as the sidecar body acts as a sounding board.

Advantages of the Sleeve Valve.

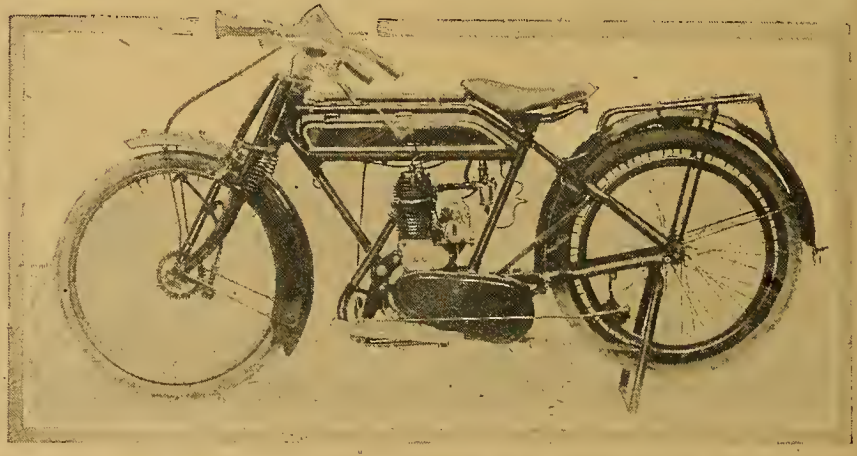
Now the sleeve valve engine has no valve noises. It can equal the poppet engine as regards power, it needs less attention as there are no seatings to be ground, and if it be proved that the moving parts wear well and that the sleeves do not seize it has a future before it which is full of promise.

It is most gratifying to be able to make the first announcement that Messrs. Barr and Stroud, Anniesland, Glasgow, have turned their attention to an engine of this type, which is already emerging from the experimental stage. This firm is, of course, well known to those of our readers who have served, or are serving, with the Navy, the Army, and the R.A.F., as it is world famous for the production of instruments demanding such accuracy of manufacture as range finders for all three arms of the Service, and fire control apparatus for His Majesty's ships.

Inlet and Exhaust.

The Barr and Stroud engine is the first air-cooled, single sleeve valve motor the making of which is to be taken up seriously. It is made under the Burt and McCollum patents, which cover the engines formerly fitted to the Argyll car, and now used on the Piccard Pictet. The bore and stroke respectively are 70 × 75 mm. (290 c.c.), and the engine is rated at 2¾ h.p. Its cylinder is of aluminium, blacked so as to aid radiation, and near the top is cast an annular induction space, in which there are four inlet ports admitting explosive mixture *via* an inlet pipe set at 45° to the fore and aft line of the engine, so that the mixture is equally distributed to each pair of ports. The fact of the induction space being so near the top of the cylinders helps to keep the detachable head cool. In its present form the two pairs of exhaust ports are connected by two aluminium castings on each side of the cylinder, which, in turn, are connected by a Y shaped exhaust pipe, the stem of the Y being below the down tube of the motor bicycle frame. Both inlet and exhaust ports, which are of peculiar shape, are covered and uncovered by means of a single sleeve, having a dual function, as it serves to do the work of both inlet and exhaust valves, and also acts as a cast iron liner for the aluminium cylinder. So far as the distribution gear is concerned, this is of more or less standard pattern, consisting of the usual train of wheels, but the engine shaft is so splined that the pinion can be fitted only in the correct position.

What would be the camshaft on an ordinary engine is a short shaft carrying two eccentrics, of which that nearest the timing wheel imparts an oscillating motion to the oil pump, while that on the further end of the shaft may be more correctly designated as a crank disc; the crank pin passes through one end of a link, the other end being



The Burt engine fitted to a motor cycle. The engine does not appear extremely unconventional.

The Barr and Stroud Sleeve Valve Engine.—attached to the sleeve by means of lugs at the top and bottom. The rotary motion imparted by this crank disc causes the sleeve to rise, and at the same time the link is forced outwards along the crank pin. Thus the sleeve is

The sleeve showing the peculiar shape of the ports.

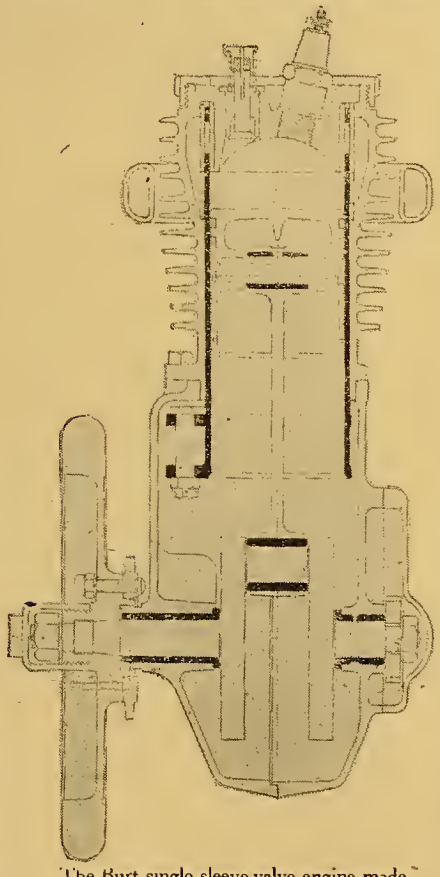
lifted about one inch and simultaneously turned about forty-five degrees. This action causes a very rapid opening and closing of the ports, as it happens when the speed of the sleeve is at its highest point. Consequently, the maximum efficiency should be obtained.

Inside the sleeve works the aluminium alloy piston, possessing two rings at the top and a drilled groove at the base so as to allow any excess of oil to escape. There is nothing very special in its design, except that inside in the centre of the head a small pyramidical point is cast dead over the oil hole in the connecting rod small end, so that oil drips exactly in the place where it is most wanted, and this device, we are told, is most effective. Aeroplane engine practice is adopted so far as the gudgeon pin fastening is concerned, as this is secured by means of a split wire ring sprung into a groove. The connecting rod is of high quality steel, and is provided with a split big end, while the crankshaft is of the solid variety of special steel provided with balance weights and drilled for lubrication.

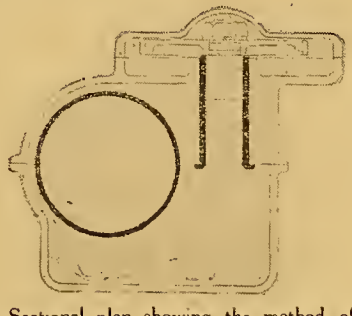
Lubrication.

We now come to the oiling system. Reference has already been made to an eccentric on the sleeve-operating shaft driving the oil pump. This latter is of the plunger type, of which the plunger works in a vertical brass barrel with a ball non-return valve at its base secured inside the crank case. The function of the pump is to deliver oil from a reservoir under pressure to the off side main bearing. Leakage from this bearing supplies oil to the timing gear, lubricant being carried up the train of wheels, and any excess being drawn off by suction on the up-stroke of the piston, through a non-return valve in the crank case. After being forced through the off side main bearing, the oil passes through the hollow crankshaft and issues through a hole in the crank pin lubricating the big end, it being flung therefrom on to the walls of the sleeve. The oil then passes to the near side main bearing, and any excess in the crank case is forced through a non-return valve at its base by the descending piston back to the reservoir.

The detachable cylinder head is of aluminium, hemispherical in shape, having a cast iron bearing for the sleeve, and carries the sparking plug and a mushroom relief valve, as no exhaust valve lifter is, of course, possible in an engine



The Burt single sleeve valve engine made by Barr and Stroud, Glasgow. Sectional elevation showing the arrangement of sleeve, ports, and cylinder head.



Sectional plan showing the method of operating the sleeve, which reciprocates and oscillates.

of this kind. This release valve is to be connected to the exhaust port, so that no noise occurs when it is brought into operation. The head is held in the cylinder by means of a castellated ring.

In outward appearance the engine strongly resembles a two-stroke, chiefly owing to the absence of valves and to the position of the exhaust port castings, while the illusion is still further aided by the fact that it has an outside flywheel, which in future models will be on the transmission side of the engine.

On the Road.

After a careful examination of the engine and its parts, we were privileged to make our first trial trip on an air-cooled sleeve valve engined motor bicycle. The bicycle to which the engine was fitted was of well-known make, fitted with chain-cum-belt transmission and a two-speed gear. In cold and damp weather, a run of about fourteen miles was made over fair roads of an undulating nature, including one fairly steep hill. An Amac carburetter was fitted, which was provided with so small a jet that the air lever could not be used, and it was therefore, to all intents and purposes, of the single lever variety. An attempt to start by paddling off on a slight up grade presented no difficulty, as the engine fired at once. With a view to testing the engine severely, and owing to the greasy nature of the road, no attempt was made to change into high gear for some time. Once clear of the bad road, the speed was increased, and no incident occurred until one of the firm's experimental staff who accompanied us led the way up a steep hill which could not be rushed. This was taken on low gear and with the throttle fully opened, but on reaching the summit the high gear was engaged without a falter, and throughout the run not a sign of a "konk" could be detected, and the engine kept remarkably cool. The next rise the engine took on top gear in excellent style, and thereafter followed a certain amount of straight road, on which a good pace was obtained. Although the makers admitted that the balance could be improved, we noticed very little to complain of in this respect, but we were truly sorry that the exhaust silencing arrangements were somewhat crude. This fact prevented us from appreciating that the engine, apart from exhaust explosions, was really quiet, and only when throttled right down could the silence of the engine be adequately realised. There was no silencer proper, merely a long exhaust pipe with a flattened end, but when throttled right down or descending a hill nothing but a muffled swish could be noticed.

The engine may be said to have emerged from its experimental stage, but at the present moment its makers are not prepared to make any statement either as regards its delivery or its production, nor are they prepared to answer any correspondence concerning it. We hope, however, to be able to make further announcements at an early date. In our opinion, the engine shows great promise. We tried hard to seize it up, but it refused to oblige us, and we believe that in its present form as a small single-cylinder, as a large V twin, or as a moderate power flat twin, it has great possibilities.

The Royal Ruby Spring Frame Solo Machine.

349 c.c. Four-stroke Engine. Two-speed Gear. Adjustable Springs.

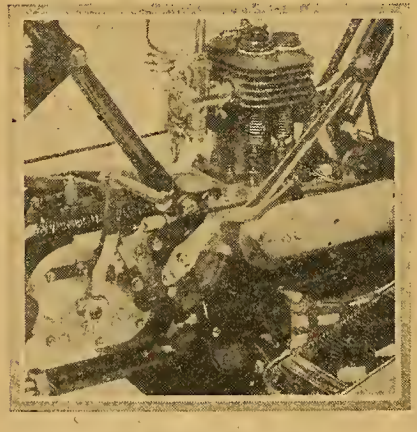
FOR some time past potential buyers of solo motor cycles have awaited with interest the advent of the new 3 h.p. Royal Ruby, which, manufactured throughout in the Ruby Cycle Co.'s own works (now very much more extensive than before the war), embodies many features of more than usual interest.

The frame is sprung front and rear by laminated leaf springs, the system of springing being somewhat unique. It is the result of several years' experiment on the part of the Royal Ruby designers. No doubt readers will recall the many references to Royal Ruby patents in this connection in *The Motor Cycle* reviews of inventions which have appeared during the past few years. The system which has been finally adopted embodies springs which are centrally disposed, and can be adjusted to the weight of the rider.

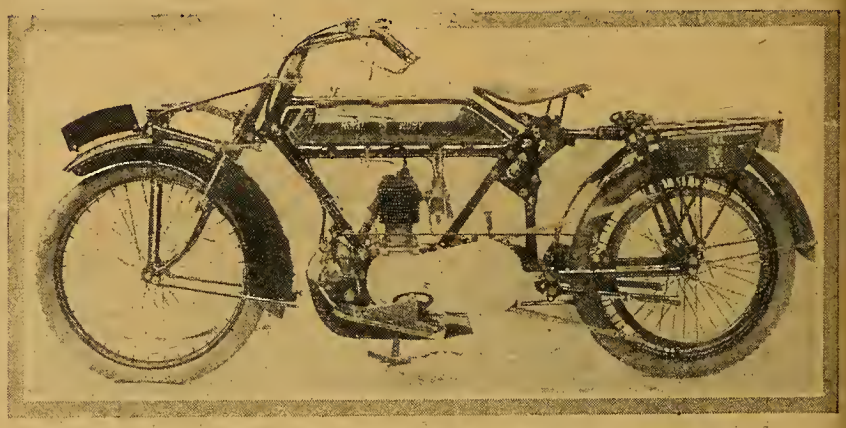
In the eyes of the springs a roller is fitted instead of the more usual practice of using shackles. This construction considerably reduces the possibility of lateral play.

Another feature of the spring frame is that it can be converted in a few seconds into rigid construction by a patented locking device, although we do not think that this option will be used very considerably, as we cannot imagine any rider who has a really efficient spring frame wishing to revert to the rigid type.

At its inner end the rear spring is carried on a saddle, which is fixed to the frame with two substantial bolts by means of a duplex structure formed of two steel pressings, which in turn are secured to the main framework by long bolts passing through lugs. At the upper end of this structure is a bearing supporting a duplex frame in which the spring is disposed. The outer end of this member contains the slides in which is the patented roller in the eye of the spring. Behind the bearing is linked an approximately vertical fork, which connects with the wheel fork near the wheel spindle.



Engine and gear box of the new 3 h.p. Royal Ruby.



The 3 h.p. spring frame Royal Ruby, which has a 349 c.c. engine, chain and belt drive, and two-speed countershaft gear.

The engine fitted is a single-cylinder four-stroke, having a bore and stroke of 74.5 and 80 mm. respectively, the capacity being 349 c.c. Side-by-side valves are fitted, and generally the unit follows more or less conventional lines. It forms a neat assembly with its silencer, magneto, and adjustable footboards. The

The laminated leaf spring fork.

exhaust pipe passes behind the magneto chain case, and the silencer is fitted directly beneath the magneto, and is supported on a platform, which is integral with the back portion of the magneto chain case. A large shield protects the magneto from mud, and is built in one with an undershield, having valances on each side of the engine.

A countershaft two-speed gear (another Royal Ruby patent), with handle-bar control, clutch, and kick starter, follows well-tried lines. This is located behind the engine, and is carried on a bracket which forms one side of a triangle in the frame construction. Immediately behind the gear box is the pivoting point of the rear wheel fork, which is supported on a long bearing, below which are the pivoting ends of the stand.

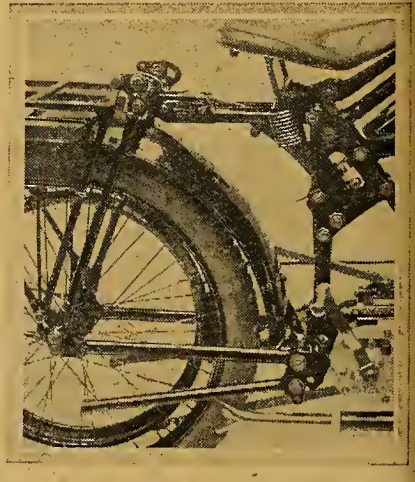
The front fork is apparently very light in construction, the frame of which consists roughly of two triangulated members connected at three points with the wheel pin to make a fourth. The motion is that of the parallel link type, and the tension of the long laminated spring is adjustable.

The transmission is by chain and belt, the wheels are 26in. × 2½in., and detachable mudguards are fitted which are 4½in. front and 6½in. rear in section.

A long stirrup is used for the front wheel brake, in the ends of which the usual type of rim brake shoes are carried, and the rear brake is of the segment type, working inside the V belt rim.

The front member of the frame is of the Triplex construction, which is a feature of the 8 h.p. Royal Ruby.

The equipment of the machine includes British-made magneto, Amac carburetter, and Brooks saddle.



The rear wheel is sprung through a leaf spring under the saddle.

Prospects for the Motor Cycle Show.

An Interview with the Management. A Bright Outlook.

TRADE and public alike have viewed with mixed feelings the advent of the first post-war Motor Cycle and Cycle Show, to be held at Olympia from the 24th to the 29th of the present month.

On the one hand, the manufacturer has been handicapped by innumerable troubles in his past season's productive programme to such an extent, indeed, that experimental work has often had to remain in abeyance, while, on the other, the potential motor cyclist has clamoured lustily for anything on wheels, adding thereto an undercurrent of demand for ideal advancement in design.

In view of this state of affairs, when most of the established firms are in arrears with their 1919 output, and the new firms are still unable to cope with their production problems, it is a moot point whether the Show is not premature. The works which cannot keep pace with the order book are surely in no need of an exhibition which will bring about an influx of orders and an impatient *clientèle* during the next year.

On the surface, this argument against the present Show would appear sound, but there are wider considerations. Those firms with fat waiting lists are tempted to carry on with their usual models: a policy invariably leading to stagnation of design. The firms newly entering the motor cycle field, many of them of long experience in other branches of engineering, bring untrammelled minds to bear on the mechanical problems involved, hence we may expect to see exhibits of new design, and suffering from no enslavement of convention. All this is to the good of the motor cyclist, who demands the best, and ultimately it is to the good of the manufacturer, who might otherwise succumb to easy practice of trading on past reputation rather than on the merits of advancing design.

In this respect, the Show is a healthy stimulus, where the ambitious designer may submit his creations to the approval of the public and the criticism of his rivals. Everyone who enters with an open mind may learn something of the trend of design, and notice, by virtue of detail improvements here and new designs there, that the trade is not standing still, but constantly endeavouring to better the goods it offers.

A further reason why the Show should be more than ordinarily popular this year is the human side. Motor cyclists, as well as workers in the industry, have been dispersed throughout the four corners of the earth during the past five years, and even those who stayed behind have largely been turned from their beaten paths. Manufacturers, their agents, and the buying public, met annually at the Show, if nowhere else. This year it will be a reunion in every sense of the term, and to many the glory and glitter of the stands will be final proof that we are again gathering up the threads of the life that were dropped in 1914.

Major H. R. Watling, General Manager of the Manufacturers and Traders' Union

From an interview with Major H. R. Watling, the general manager of the Cycle and Motor Cycle Manufacturers' and Traders' Union, which we sought, with a view to learning the feelings of the trade generally with regard to the present Show, we learned that the prospects of its success are indeed rosy. While no one, it is true, can state the definite amount of public support, he instanced the enormous growth of interest in automobilism, more particularly in the motor cycle, which has resulted from the experience of the past five years.

In its technical aspects, too, the 1919 Show will be unique; many old-established engineering firms have entered the motor cycle trade, bringing unbiassed minds to the subject. Their products are sure to be characterised by novelty.

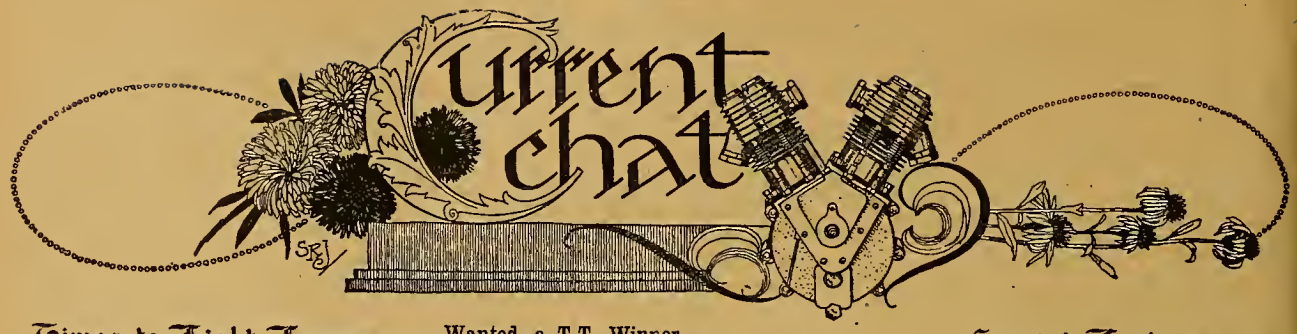
Numerically, we were told, the total number of exhibitors exceeds the number represented in 1913, when the last Show was held, and, furthermore, the tendency is for the motor cycle exhibits to increase in quantity at the expense of the pedal cycles which will be staged.

A new phase of the Show is the scooter development, public interest in which has grown from the smallest possible beginning in the present year to such a degree that many motor cycle manufacturers have felt impelled to experiment in this direction. Our question as to the feeling of the trade, as regards the scooter and its ultimate development, was met by the answer that at present it is too early to speak of a settled attitude, since the whole matter is in a state of flux; much will be learned at the Show by the amount of attention paid to the exhibits of those firms who stage scooters exclusively.

Finally, touching the question of prices, Major Watling assured us that no likelihood of a fall was imminent, since it must be remembered that alone amongst engineering products the average price of motor cycles had not, as a whole, attained the 100% increase.

Taken altogether, the 1919 Show promises to be an exceptionally successful one, and every effort is being made to render it popular in every sense of the term—the charge for admission will be two shillings each day, from 10 a.m. to 10 p.m., and there will be no "special" days and correspondingly higher prices as in the case of the car show.

The enormous detail work involved in show organisation, which has fully occupied the attention of Major Watling and his staff for some time past, and which grows momentarily as the time for opening the doors to the public approaches, has been well handled, in spite of more than ordinary difficulties, and the motor-cycling public is assured of an exhibition in every way as successful and technically interesting as any of its predecessors.



Times to Light Lamps.

GREENWICH TIME.

Nov.	20th	4.34 p.m.
,,	22nd	4.31 p.m.
,,	24th	4.29 p.m.
,,	26th	4.27 p.m.

Benzole.

In view of the recently completed benzole test, a rider of a 3½ h.p. Ariel writes that he has ridden upwards of 8,000 miles, using benzole throughout, and yet his engine is as good as new. This does not in any way surprise us.

Expert Motor Cyclists.

The following names have been added by the Auto Cycle Union to the official expert competitors' class: J. A. Newman, T. C. de la Hay, H. S. Noakes, R. F. Pugh, A. Butterfield, and F. W. Applebee.

A Six Days Trial Award.

In the course of the final examination of the competing motor cycles at the conclusion of the recent Auto Cycle Union Six Days Reliability Trial, the judges considered that a brazed joint on one of the Matchless sidecar chassis showed signs of movement, and marks were provisionally deducted for this defect. Having submitted the joint to miscroscopical examination, which showed the brazing to be sound, C. R. Collier, the entrant of the machine in question, has therefore had the marks deducted for this defect to him restored, and is in consequence awarded a gold medal.

Imports and Exports.

There is a curious discrepancy in the average prices of motor cycles imported in September with the imports of October. The Board of Trade returns say that in September the value of the 188 motor cycles brought in was £11,713, an average of a little over £62. Whereas last month the number was 142 valued at £4,313, an average of just over £30.

We have not heard of a big influx of lightweights at competitive prices reaching this country, but probably a fairly heavy importation of motor wheels or motor attachments accounts for the low average price.

EXPORTS.

The value of exported motor cycles, parts, and accessories for October shows a slight decline of £5,000 on the previous month's figures, chiefly made up in a decline of accessory exports.

EXPORTS FOR OCTOBER.

	1917	1918.	1919.
Value of motor cycles, parts and accessories	£268,269	£65,628	£103,343

Wanted, a T.T. Winner.

Owing to the large number of letters which we received in reply to the paragraph recently inserted asking for a potential T.T. winner, it is impossible to reply to all individually. All who sent their names are cordially thanked by the firm interested in the matter, which is having consideration.

The Paris-Nice Trial.

We hear that there will be quite a large entry for the Paris-Nice Trial. From Belgium, several Brussels riders have sent in their entries, while entries have also been received from Geneva and Milan. There are reported to be twenty-three Harley-Davidson entries.

Grove Park Workhouse.

This week Grove Park Workhouse will be handed back to the Grove Park Guardians after being used as a M.T. depot for five years. Hundreds of A.S.C.M.T. motor cyclists passed the tests at Grove Park, and thousands of motor cycles received treatment in the workhouse shops. A litter of derelict petrol cans is all that remains.

An Invitation to Motor Cyclists.

The Auto Cycle Union hopes that all motor cyclists visiting the Olympia Show will, in the event of their requiring advice or information, pay a visit to Stand No. 2, where officials of the Union will be ready to render whatever assistance is possible. This invitation is extended to all riders, whether they are members of the A.C.U. or not. Members will probably find the writing and waiting room, which has been set apart for them, of great value in view of the enormous crowds which are likely to visit the exhibition.

A Meeting at Olympia.

A meeting of delegates from each of the territorial districts in which the motor cycling clubs have been grouped by the Auto Cycle Union will be held at Olympia at 5.30 p.m. on Thursday, November 27th, during the motor cycle exhibition. Delegates are asked to accept this notice as a summons to attend. The meeting is for the purpose of arranging dates for the more important motor cycling competitions in 1920.

Members of the A.C.U. will have the exclusive use of the Princes' Rooms, where a lounge and facilities for correspondence and refreshments will be available. Officials of the Union will be ready to give information and advice to all motor cyclists on any subject connected with the movement, and to explain the advantages of membership of the Union.

Special Features.

SHOW FORECAST.
HOW TO REACH OLYMPIA.
1920 MODELS.

Looking Ahead.

The Marseilles Motor Club will hold the Marseilles-Monte Carlo trial on April 4th, 1920, and the Mont Ventoux hill-climb on August 8th, 1920.

The Metropolitan Police and Lighting.

The police are very active in the neighbourhood of Hampton Court, stopping any motorists whose rear lights have gone out. As the road from Hampton Court to Staines is in vile condition, it is very difficult to keep rear lamps alight.

A Meeting of the I.A.E. at Olympia.

A meeting of the Institution of Automobile Engineers will be held at Olympia on Thursday, November 27th, at 2.30. All those who are interested will be cordially welcome, whether they are members of the Institution or not, as the Council is most anxious to afford every opportunity for the discussion of motor cycle design, with a view of evolving the best possible type of motor cycle.

South Birmingham M.C.C. Palmer Cup Open Trial Awards.

Owing to the general severity of the course, no marks were deducted for variations at time checks.

The winner of the Palmer Cup proved to be G. Kuhn, riding a 293 c.c. Levis; he also takes the Cameta Service Cup, his total marks being 239. B. L. Bird (4¼ B.S.A.) secured the Upton Cup with 232 marks, J. H. Walker (4 Triumph) gaining 228 marks and the Cooper Cup, while the only other award was obtained by A. Milner (2¾ Diamond), who qualified for a silver medal with 215 marks.

It will be remembered that Kuhn also secured the Victory Cup in the first post-war open trial held in the Midlands.

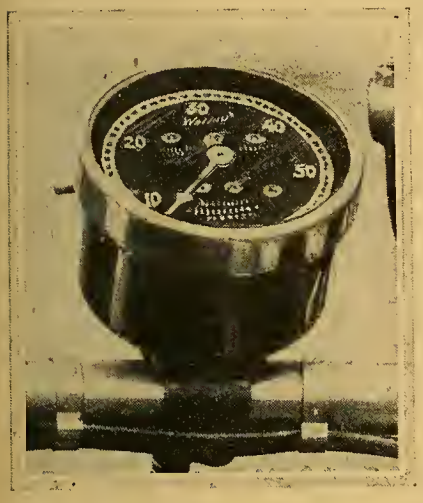
A Trial for Scooters.

The Auto Cycle Union has received several letters from motor scooter manufacturers promising support for the suggested trial next spring. The manufacturers have indicated their appreciation of the various tests to which the A.C.U. proposes to put the scooters entered in the competition. These include general reliability, petrol and oil consumption, steering, flexibility, and all the essentials of this type of vehicle. There is no doubt that very wide interest will be evoked by the trial, and it is being keenly anticipated by many prospective scooter users.

ACCESSORIES FOR 1920.

A Few of the Large Number of Equipment Details which will be offered Next Year.

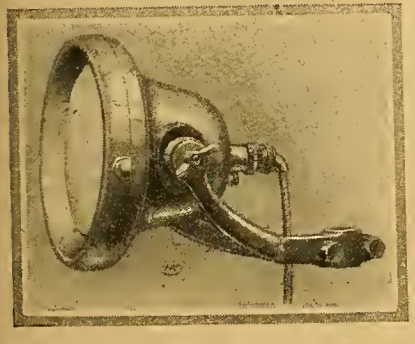
S. North and Sons, Ltd. (Stand 210).—The chief item of interest to motor cyclists exhibited by this firm will be the Watford speedometer. Black dials are among the chief innovations in the latest model. The fingers are white, and the contrast renders the instrument very easy to read. Rear drive is now becoming



The new Watford speedometer, which has a black dial.

very popular among motor cyclists; it is superior in many ways to front drive, as the cable does not have to withstand the vibration of the sprung front forks. The new Watford drive is very cleverly carried out, and when once the driving sprocket has been centred on the wheel, the adjustment of the driving sprocket is quite a simple matter, owing to the numerous adjustments which may be made on the bracket which holds it. The speedometer itself works on the centrifugal principle.

C. A. Vandervell and Co., Ltd. (Stand 166).—Messrs. C. A. Vandervell and Co., Ltd., will be exhibiting C.A.V. magnetos, which were amongst the first motor cycle magnetos to be made in England. One of the most popular models is the K.U.T. for twin-cylinder engines, rated up to 3 h.p. and firing at 180°.

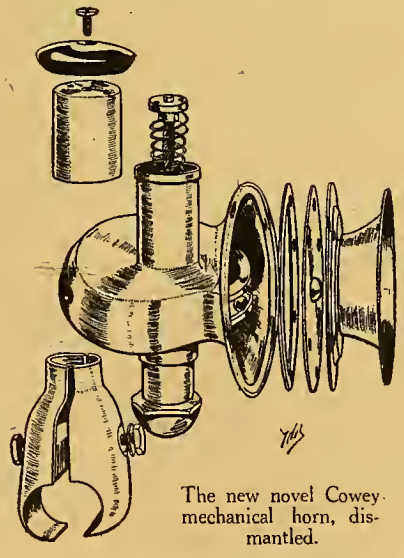


A neat electric head light, by C. A. Vandervell and Co.

There are two important features in the C.A.V. magneto: the excellent high-tension terminal, which is quite water-tight, and the C.A.V. contact breaker, which is actuated by a fibre roller, and contains no rocker arm with its troublesome fibre bush, which is apt to stick in damp weather.

A speciality is also made of electric lighting by accumulators for motor cycles and sidecars. Special sets are made up for passenger outfits, which are designed so as to take up very little room in the locker of the sidecar. The question of lamps has long been studied, and C.A.V. lamps are particularly efficient, giving a powerful beam ahead. Head lamps, tail, and side lamps are provided, and a neat and compact switchboard.

The Cowey Engineering Company, Ltd. (Stand 196).—The chief feature of the exhibits of the Cowey Engineering Company, Ltd., will be the attractive Cowey horn, designed to be fitted either to the handle-bar or the top tube of a motor bicycle. It is noteworthy for its smooth exterior and attractive appearance. This is a very handsome and ingenious contrivance, and will naturally be seen on many motor bicycles during the coming season. It consists mainly of a highly polished and well-finished aluminium



The new novel Cowey mechanical horn, dismantled.

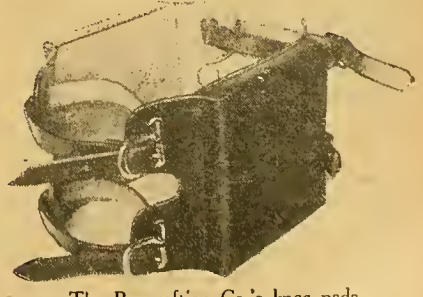
body, and is fitted with a plated bell mouth, the general effect being excellent. The interior construction is not without interest. The depression of the black knob at the top of the horn causes a threaded rod to give a rotary motion, on the principle of the Archimedean drill, to a horizontal disc in which balls are loosely held at intervals. These balls are secured in a cage, and, while capable of movement, are prevented from leaving the cage altogether. The action of rotating the disc is to cause the balls to fly outwards through centrifugal force, and as they do so they hit the pin in the centre of the diaphragm, thus giving an excellent warning note, which may be varied from a medium noise to one loud enough to satisfy the most fastidious motor cyclist. The Cowey speedometer, which has been so long popular among motor cyclists will also be shown. It is to be had either with or without trip, and may be finished in either bright nickel or plated and black. A cycle car model will also be exhibited, of lacquered brass, bright nickel, or black nickel, with a bracket or flush fittings, and with front wheel or cardan-shaft drive. The speedometers just mentioned are calibrated up to 65 m.p.h., but at a slightly extra cost may be calibrated up to 90 m.p.h.

Dover, Ltd. (Stand 225).—In view of the large amount of correspondence in *The Motor Cycle* respecting "Roadside Courtesy," the new Dover signal, no doubt, will create a certain amount of interest among those motor cyclists who

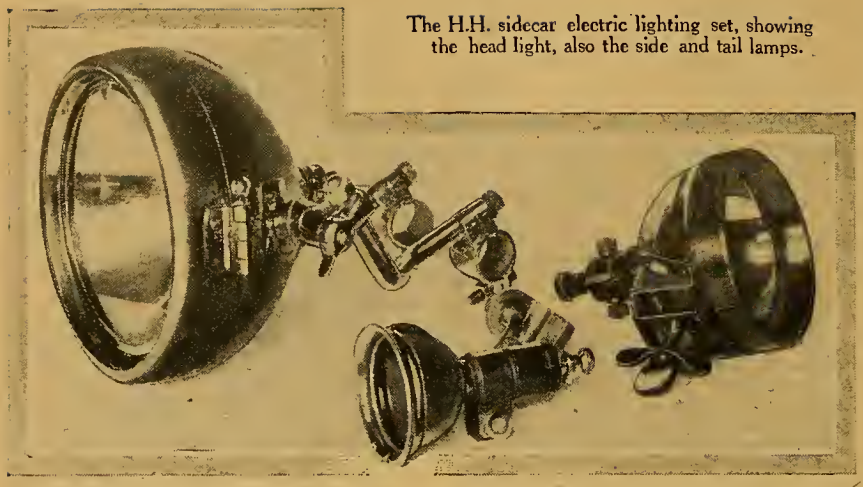
The Dover signal device.

wish to display a sign, when resting, that they are not in need of assistance, or *vice versa*. The signal consists of two triangles, of white and red respectively, on swivelling arms which, under normal conditions, are intended to be carried alongside the front mudguard extension.

The Bancroftian Co.—Although not being exhibited at Olympia, this firm's accessories will be on view at its city showrooms, 64, Bishopsgate, London, E.C.2. While visiting the depot recently we were enabled to see for the first time the new Cowey mechanical horn. The Bancroftian Co. has lately placed on the market some moderately-priced goggles, made of mica and with green tops, which should be very useful in counteracting the glare of the sun during the summer weather. This firm is one of the few that, at the present time, can give delivery of Cowey, Watford, and Stewart speedometers from stock, with or without trip. It is also in the fortunate position of being able to supply chains, which are exceedingly hard to obtain just now. Yet another of its specialities is sidecar bodies, which are both well upholstered and well finished.



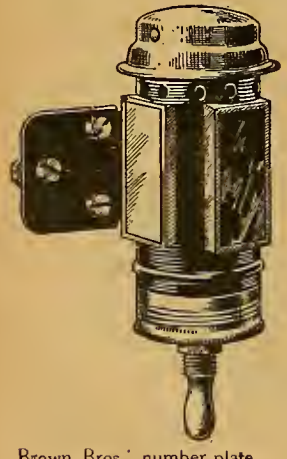
The Bancroftian Co.'s knee pads.



The H.H. sidecar electric lighting set, showing the head light, also the side and tail lamps.

A. H. Hunt (Stand 178).—For many years the firm of A. H. Hnnt has been famous for the production of beautifully-finished and powerful electric lamps to suit not only the large sidecar ontfit, bnt lightweight meter bicycles as well. The current is derived from either the well-known Hellesen dry batteries or from accumulators. Hellesen dry batteries are among the most efficient on the market, and their recnperative powers and lasting properties, especially if they are used for short distances, are extraordinary. A very useful accessory te be found on this stand is the H.H. hand lamp, which is invaluable fer use in the motor house. One of these, in eur pessession, has been used for two and a half years, and the battery is still as sonnd as on the day it was delivered, even though it has been carried in the hand and used as a head light while riding a moter bicycle. Numerous electrical accessories will also be shewn. Among these may be mentioned a particularly neat lamp switch, which is operated by a small screw in the vulcanite casing, which makes contact between two metal blocks. It is positive in action, and should prove to be most reliable.

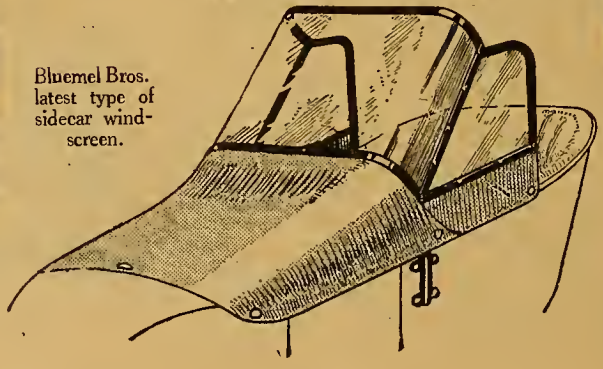
Brown Bros. (Stand 164).—During the present year, Messrs. Brown Bros., Ltd., have shown great activity in the production of motering accessories. Among the many fitments which will be exhibited by this firm may be mentioned a neat little tail lamp and a handle-bar mirror. The top of the tail lamp, which is finished in black, opens, allewing access te the burner for lighting. The white glass at the side and the red glass at the rear are held in position by a piece of coiled steel wire, which keeps them securely in place and yet allows them to be withdrawn with the greatest ease for the purpose of replacing or cleaning. The mirror is light and well-made, has a nniversal movement, and is well-finished. This device should cemmend itself to all motor cyclists who favour this useful type of accessory.



Brown Bros.' number plate and rear lamp.

Bluemel Bros., Ltd. (Stand 161).—Undoubtedly the majority of sidecar passengers agree that their comfort is enhanced a hnndredfold when an efficient windscreen is fitted. Messrs. Bluemels have for some time realised the demand for such fitments, and have extensively experimented in this directien during the past year, with the result that a Bluemel patent windscreen will be offered to the public for 1920, and our considered verdict is that it is likely to be very popular. In the first place, the front part of the celluloid screen is curved, and side extensions are fitted, which prevent side draughts. All three panels are fitted in light enamelled steel frames, and below the assembly a waterpreof apron covers in the space between the shield and the body work at the front and sides of the sidecar.

Sandham Engineering Co. (Stand 15a).—In addition to the sidecars which will be exhibited by this firm, a simple screen also will be shown. It consists merely of two adjustable metal tubes which are screwed, by means of the clamps provided, to each side of the body. Carried between them is a screen held at its upper and lower edges by a band of Cape cart hood material. By slackening the fly-bolt at the lower end of each tube, the screen may be tilted at any angle to suit the passenger. A storm hood and screen also will be staged, which consists of the conventional type of sidecar hood having two side flaps which are a permanent fixture. Immediately at the front of the hood is a reller blind, con-

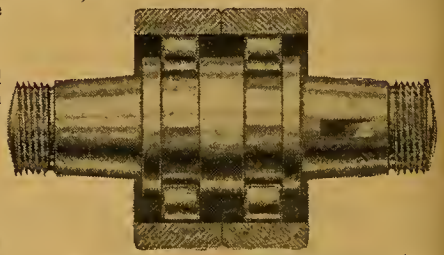


Bluemel Bros. latest type of sidecar windscreen.

A new windscreen, produced at a moderate price by the Sandham Engineering Co.

structed of waterproof material, which, when the occasion arises, may be pulled down and clipped to the two front stays of the hood so as to protect the passenger from the elements. An oval window is provided in the roller blind, and twe similar windews in either side ef the hood. The complete fitting may be erected in a few seconds, and should be found of extreme utility te motor cyclists who find themselves suddenly caught in a storm.

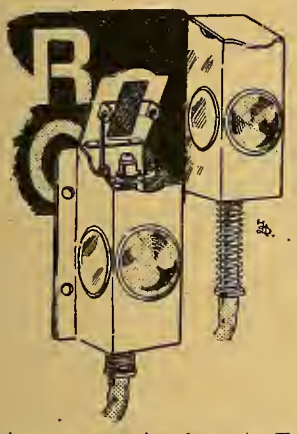
Hoffmann Manufacturing Co. (Stand 235).—Roller bearings are new becoming so popular with designers of all types of engines that the exhibit of the Hoffmann Co. will interest many visitors to the Show. A full range of ball and roller bearings will be displayed, together with a model of a moter cycle engine, the main bearing and big end of which have been fitted with Hoffmann roller bearings



One of the many types of Hoffmann roller bearings.

Accessories for 1920.—

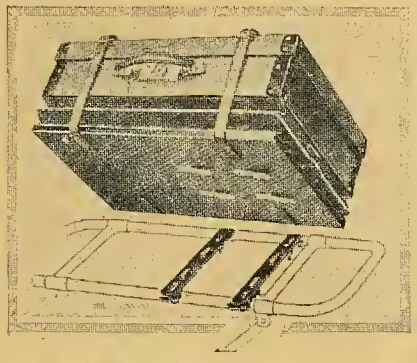
TAN SAD WORKS (Stand 211).—Among the several new units for the well-known pillion seat, which will be introduced on the Tan Sad stand, will be a neat little rear lamp which has a spring lid. By lifting this, the burner of the lamp is caused to rise into a position convenient for lighting. In the lid is a roughened



A new rear acetylene lamp, the Tan Sad. The lamp on the left (showing the method of opening) is sold separately, the one on the right can be obtained with number plate attached.

strip for striking the match, so placed that a downward stroke should ignite the match and gas at the burner almost simultaneously, thereby removing one of the greatest troubles in connection with lamps which have to be lighted by a match in high winds. The other specialities of this firm are referred to elsewhere in this issue.

LEATHERIES, LTD. (Stand 229).—In addition to saddles of all types for cycles and motor cycles, Messrs. Leatheries, Ltd., will exhibit a comprehensive range of general leather equipment of interest to the motor cyclist, chief among which we would mention the collapsible valise for fixing to the carrier. The framing is permanently secured to the machine by four sliding clips, which enable it to fit almost any type of carrier. To the upper side, four metal loops are riveted, and on the underside of the valise are four metal plates which fit into the loops. The valise is held in place by means of one fly nut and bolt attached to the framing, and which engages with a recess in the metal plate. When expanded, the valises measure $14\frac{1}{2} \times 9\frac{1}{2} \times 5\frac{1}{2}$in., $16\frac{1}{2} \times 11 \times 6\frac{1}{2}$in., and $18\frac{1}{2} \times 12\frac{1}{2} \times 7\frac{1}{2}$in. The prices of the respective sizes are 22s. 6d., 26s. 6d., and 31s. 6d. This is only one



A useful expanding touring bag, by the Leatheries Co.

of the many propositions in motor cycle equipment.

GRINDLAY, LTD. (Stand 30).—This Coventry sidecar firm is exhibiting at Olympia a new adjustable sidecar screen, which is of the conventional framed type,

The new Grindlay sidecar screen, a neat model that can be adjusted to any position.

fitted on to hinged tubular extension arms, by means of which the screen may be placed in any position between the passenger and the front of the sidecar. In addition, the screen may be placed on the slant, if it is desired to divert the air current away from the passenger.

A full and illustrated report on the accessories at Olympia will be contained in *The Motor Cycle* Special Accessory Number, December 4th.

Birmingham M.C.C. Trial for the Sangster Cup.

A Club Members' Competition held in Dense Fog.

ORIGINALLY intended to be run over a difficult course, the route was changed at the last moment so as to give club members an opportunity of ending the season by competing for the cup on an easy course—Birmingham to the Wrekin, *via* Castle Bromwich, Brownhills, Ivetsey Bank, and Wellington, returning by the same route—apparently an easy task, yet out of the thirty-one starters only five came through with full marks, therefore it does not appear necessary to run trials over had ground and through unknown lanes.

On Saturday, Birmingham was enveloped in a dense fog, through which it was impossible to see more than a few yards. Yet of the thirty-three entrants thirty-one started from Selly Oak, on what proved to a good many an adventurous journey.

The first test commenced the moment the men were started, for the route from Selly Oak to Castle Bromwich led through the heart of Birmingham, and to average 20 m.p.h. in clear weather would not be an easy task; in the dense fog it proved an impossibility, and it was no surprise to the checker at Castle Bromwich (not a time check) to find all competitors considerably behind time.

Fortunately, in places *en route* the fog cleared slightly, enabling the men to make up time, which was easily accomplished over the Watling Street to Wellington.

Patches of dense fog were run into, and serious accidents only avoided by driving with the greatest of care.

Nearing Wellington, a paper trail was laid, which led the competitors to Forest Glen *via* a good hard road. Turning through the gate the ascent to the Wrekin was commenced.

After leaving the main road at Wellington the climb commences, not severe until the gate is reached, but sufficient to warm the engines up. On reaching the gate the gradient becomes steeper, and there were many failures at the hairpin, caused principally through bad acceleration after rounding the bend. Eighteen failed at this point.

No sidecar combination succeeded in making a clean ascent. Saddington, on a 5-6 h.p. James, was the only one of the sidecar class that succeeded in the stop and restart. Amongst the solo riders good performances were made by Duke (Triumph), Kuhn (Levis), Kershaw (Verus), Silver (Quadrant), Strange (James), Walker (Triumph), Bird (B.S.A.), Milner (Diamond), Watson Bourne (Blackburne), Neave (Sunbeam), and Atcherley (Triumph).

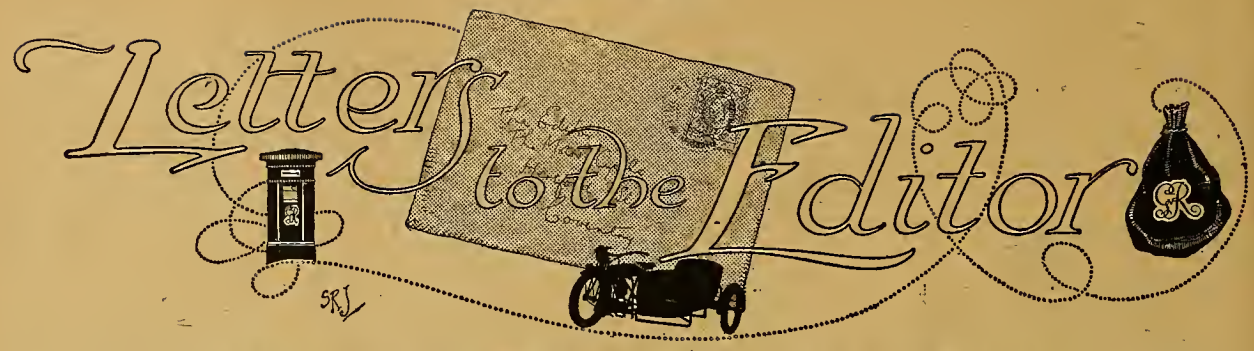
After passing the stop and restart tapes, stoppages were plentiful before reaching the tea rooms—time check.

Here the trials hon. sec., Mr. T. Silver, had ready a good substantial lunch for the frozen competitors, most of whom showed signs of a strenuous journey.

After lunch the acceleration and brake test was held on a perfectly straight, flat road. Competitors were timed from start to finish of the acceleration section, a distance of seventy-five yards, and had to pull up in brake section, which was marked off in yards, the results being obtained by adding the time and distance.

After leaving the glen, fog again enveloped the competitors, the bank continuing right to Brownhills, where it cleared. Near Brownhills a surprise brake test was laid, but the competitors were too wary to be caught. If the brake test did not serve the purpose intended, it certainly caused the men to ride with caution through the bank of fog.

Duke, Strange, Kuhn, J. Walker, and Bird lost no marks and tied for the cup. The winner will be found when the acceleration test results are worked out.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters must be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE VALUE OF THE AUTOMOBILE ASSOCIATIONS.

Sir,—Although one is constantly reading about the difficulty of obtaining spares, it appears that the A.A. can give very great assistance in this matter.

The other day, I broke two piston rings and was held up. It was most important that I should be able to use my machine immediately, but I could not get any rings locally or in any of the surrounding towns. I wrote to the A.A. at Birmingham, and, much to my delight and astonishment, I received the rings by return and express post, though the A.A. people had difficulty in obtaining them.

J. S. LOPKINS.

TAPPET CLEARANCES.

Sir,—The question of tappet clearances for four-stroke air-cooled engines is an important one. Doubtless different fuels give different results. Using a mixture of naphthalene and petrol and tappets (B.S.A.) set to five thousandth of an inch cold, I notice, as the engine warms up to average travelling heat, the clearance increases enormously, and, strange to say, very nearly as much in the exhaust as in the inlet, but, if the engine is run hard uphill on second gear and made very hot, the exhaust clearance begins to reduce.

I am sure some opinions on this subject would be very interesting and instructive. B.S.A.

Stoke-on-Trent.

A COMMENT.

Sir,—In reply to your correspondent Henry Evans, who asks what rider of a Triumph is troubled with his machine shedding nuts, I may state that my 1919 Triumph has twice lost one of the small screws which hold the under side of the toolbag case to the carrier stays. In both cases the screw was as tight as an ordinary screwdriver could make it. Major Kennedy in his "Candid Criticism" says: "There are a number of small screws in connection with toolbags which tend to lose themselves." Perhaps he has lost some, too. In conclusion, I should like fully to endorse what has been said about gear changing with the foot. I find it quite easy, however, without having the end of the lever bent.

A. WELCH.

A LADY'S RIDE.

Sir,—Do you care to record this run, which I did on my solo motor bicycle (two-stroke) in a day in September last? I left Bournemouth in the morning early, and got up to Stamford (North Lincs.) at 6.30 p.m., stopping an hour in Winchester and another in Oxford, going by way of Ringwood, Romsey, Winchester, Newbury, Oxford, Bicester, Towcester, Kettering, Stamford, and did the same run back to Bournemouth four days after.

There is a good deal said about the two-stroke being only a "potterer's mount," and I daresay other two-stroke riders like myself who have ridden motor bicycles such as the Triumph and Douglas would not hesitate to choose either of the two last named; but when it is a case of expense, and perhaps having to wait months before being able to be supplied with one, it is better to take and make the most of what one can get and be thankful, especially in, shall I say, these striking times!

My motor bicycle is a Connaught, and I did the journey on just over one gallon and a half, as I have an extra air valve fitted to my carburetter.

I. V. CORRIE (Miss).

SHAFT DRIVE.

Sir,—Letters such as that of "All Belt" make me tired! He is welcome, so far as I am concerned, to extol the merits of all-belt drive, though I doubt if his letter will prove convincing to all-weather sidecarists. About chain drive, its merits and demerits, he appears to know little, while of shaft-drive in motor cycle practice he obviously knows nothing. He asks, "If shaft drive is ideal, why is it not in more general use?" Apparently, in "All-belt's" world, the real and the ideal are mainly synonymous. I wish it were so in my world! I do not find the methods in "general use" are usually ideal.

But to conclude. Belt drive (of which I know nothing) evidently suits some riders admirably. Chain drive I have proved to be excellent, though it has serious drawbacks, which its users generally discover. Shaft drive has given me unqualified satisfaction in many thousands of miles of sidecaring. I do not trouble whether it is "ideal" or not; it is the best thing in transmission I have struck. FN 1240.

Newbury.

KICK STARTERS.

Sir,—May I presume on a little of your space in reply to "B.J." (October 30th)?

I had trouble in starting my Sunbeam (chain-cum-belt model) at first, but found that starting depends chiefly on three factors—*(a)* the petrol, *(b)* the lubricating oil, and *(c)* the moment of dropping the exhaust.

With regard to *(a)*, I find starting much easier when (to use an Irishism) the petrol is benzole.

(b) I think the oil recommended, viz., Castrol "C," is rather too heavy, and get much easier starting with a slightly lighter oil.

(c) is, of course, a knack, which is easily acquired.

With benzole and a suitable lubricating oil I usually started up with two or three kicks in cold and first kick when hot.

In very cold weather it is sometimes a good thing to dope the cylinder and then kick several times, with the exhaust lifted, to ease the piston.

Like "B.J.," I have no fault to find with the machine, which runs splendidly.

I hope this may be of use to "B.J."

A. F. SCROGGS.

THE LIGHTING REGULATIONS.

Sir,—Having read the opinions on rear lighting expressed by "Sivel" in your issue of November 6th, I feel that I cannot pass over such an absurd letter without some comment.

First, your correspondent says, "In addition to cyclists, one will occasionally come across pedestrians, cattle, stray horses, broken down carts, parcels dropped from vehicles, bricks, and numerous other possible sources of trouble." "Why," he asks, "should not these have to carry lights as well as bicycles?" Those whom he calls the "enthusiasts of the rear light" know well enough that there must be pedestrians on the road. These usually have the sense to get out of the way; but as to the rest, well, one *might* happen to fall down a hole made by an earthquake on a dark night! These are ordinary risks, which any night rider, fast or slow, has to take, and have nothing whatever to do with the subject of rear lights on bicycles. Many other dangers cannot be guarded against. The danger of colliding

with a bicycle can; and surely it were better to have one less danger on the road, for the exercise of a little trouble? Motorists and motor cyclists have to carry rear lamps; why not cyclists, to whom they are far more of a safeguard.

Lastly, your correspondent states that he would always carry a rear lamp himself on a push bicycle. He thus admits the wisdom of the course.

His remarks as to road hogs need little comment. The percentage of these is no greater than that of cyclists who ride across main roads as hard as they can without giving warning. IORWARTH.

Cambridge.

Sir,—In view of the letters in your issue for November 6th protesting against your leading article on the lighting regulations, I feel bound to let you know that there are some of your readers who entirely endorse your views. It is obviously absurd to try and make out that the cyclist has no responsibility for his own safety on the roads at night, and equally absurd to contend that the rear light is no safeguard. In fact, the whole case of the cyclists who oppose the regulation may be summed up in the one word laziness.

Your correspondent Isaac Bartu admits as much in the last paragraph of his effusion. Surely while the unfortunate motorist or sidecarist has to "mess about" with no fewer than three lamps "in the dark and cold," the cyclist should not complain at having to use one extra lamp of a much simpler pattern usually. It is not therefore right that all the responsibility should be thrown on the shoulders of the motorist, merely to excuse the sheer laziness of the cycling element of the community. As regards safety, there can, of course, be no doubt of the advantages of the rear lamp.

I may state in support of my impartiality that I have been for many years both a cyclist and a motor cyclist, and as such have had plenty of opportunity for studying the subject from both sides. M5229.

Oxford.

Sir,—With regard to this vexed question, and particularly with reference to the correspondence referred to by "Sivel" as appearing in the press, and to his own letter, in my opinion much of the discussion fails utterly to touch the real point at issue, and to get to the true merits of the case. Surely the real question is as to whether lights, including rear lights, should be displayed by all vehicles using the roads in the dark, or by none—the word vehicles being used in a comprehensive sense, and to include all road users that can reasonably and conveniently carry a light. "Sivel" refers to pedestrians, parcels dropped, and bricks. What are we to infer from this? Surely this argument means that, because a parcel dropped from a van, or a brick in the road, cannot be compelled to exhibit head and rear lights, these are unnecessary on cycles, and, presumably, superfluous on larger vehicles. Does he advocate the abolition of all lights? If so, it must be prohibition of lights on vehicles, because nothing could be more dangerous, both in country lanes and city streets, than the intermingling of lighted and unlighted vehicles, especially as, even in London, fogs and mist are not unknown. Of course, if and when we have the "Prohibition of Lights on Vehicles" Order during a fog, traffic will cease entirely. If that does not suit "Sivel," we are back at the only safe alternative—compulsory lights, front and rear, on all vehicles. He cannot have it both ways, and for lights to be compulsory only during certain climatic conditions is, I think I may safely say, quite impracticable.

Anyway, why is there so much objection to "rear" lights? If any class of road users are of opinion that they should be favoured to the extent of being required to carry one light only, why not agitate for the abolition of front lights? Oncoming traffic passes on the other side of the road, and, if any light is wanted at all, it is surely for that portion of the traffic that is using the same track, and as I can conceive of no useful purpose whatever served by a rear light on an overtaking vehicle, the only use left for the light is to manifest the presence of a vehicle being overtaken. Further, if there is to be any differentiation of treatment as between the various sections of road users, the only claimants who can reasonably plead for exemption are those who most frequently overtake and are not overtaken, and the compulsion to carry lights should be most strongly enforced on those who are more frequently overtaken.

Personally, I fail to see why any class of vehicle should be particularly penalised, or particularly favoured, and we are thus back again at my original contention, viz., either that all should carry effective front and rear lights, or that all lights should be prohibited. The impracticability of the second alternative under certain climatic conditions prevalent during the darker months of the year—rain, mist, or fog—render the first alternative the only safe and logical one.

Hornsey. SOMMON CENSE.

HONOUR TO WHOM HONOUR!

Sir,—I am sorry to disturb the harmony of the mutual admiration society which is holding its meetings in your columns under this heading, but—

Three weeks ago my back wheel was run into by a lorry, and so buckled that a new tyre rim is the only possible repair.

The machine is 1919 pattern—in fact, brand new a few days before the accident.

A new rim was ordered from the makers—a well-known firm—the same day by the repairers who have my machine. Since then both they and I have asked the makers to hurry, explaining that the machine is required for daily use.

I have no interest whatever in the firm beyond that of a customer who would no doubt be satisfied if his machine had a back wheel in it, and so enabled him to acquire satisfaction, twice daily, at 8.15 a.m. and 7 p.m.

Oh! ye motor cycle manufacturers! Search in your hearts and order books, lest, peradventure, ye be the culprits. So that I may have my rim: and ye, the shekels therefor; and my blessing on yourselves, your successors, and assigns, in fee simple, and free from incumbrances.

Slough. VERBUM SATIS FACIENTI?

CLUB CHAMPIONSHIP IN HOLLAND.

A scene in the recent inter-club team trial which took place in Holland. Eight teams of three competed, and twenty-one riders survived the course, which was very treacherous owing to rain.

Sir,—I should like to add my testimony on this subject concerning the only firm with whom I have dealt.

I have had from the Sunbeam people a 2¾ h.p., a 3½ h.p., and an 8 h.p. machine in succession, starting the first-named as a complete novice. The firm of John Marston then impressed on me that they did not lose interest in their machines when they left the works, and that I was to write to them in all cases of difficulty, though they did not expect that I should have any difficulties that were not of my own making. I can only say that they have absolutely acted up to their principles, and on the few occasions when anything went wrong, as it did once or twice without blame to the machine, the firm acted with the utmost promptitude and generosity. If the demands of the working-man will allow it, I shall never have another brand of motor cycle. I have no connection with the firm except that of a highly satisfied customer.

The weekly testimony of your readers is like the housemaid's character—taken altogether it is more interesting for the names that do not appear! G. T. PARRATT.

Woking.

THE MOTOR CAR ACTS, 1896-1903.

Sir,—I am with Mr. Jones in his protest against the interference and persecution of motorists by the police and magistrates of certain particular districts.

Of course, concerted action is the only remedy; but how are we going to get it? Letters to motoring journals are not much use. The daily press is the power that moves the authorities, and I do not think we are likely to get help from that source. At present the daily press only publishes very short articles of any interest to motorists and reports from police proceedings against the really bad and careless driver, which only prejudice public opinion. We can read in the daily papers of a motor car that ran from Scotland to London during the strike at a speed that exceeded the legal limit, and wonder whether the police trappers had found some other work. The Automobile Association advertises that it was requested by the authorities to organise many thousands of willing motorists against the railway strike, and it tells us that during that "black week" the motorist was the man of the moment. All that sort of thing is very good.

The advertised fact that a motor car can be driven safely at a speed exceeding 20 m.p.h., and that the motor car or cycle owner is quite a potential and respectable member of society does not seem to bear weight with the authorities in certain districts, and the above obsolete Acts are still being used to employ the police and provide a source of revenue.

We cannot hope for anything different while the average motorist is so apathetic and content to be merely tolerated on the roads, and I do not think motorists could organise strongly enough to force the authorities to let up on a system of persecution which is so profitable to themselves. And I think public opinion is still with them, and helped on by the motorist who does more mileage round the houses than the open road.

Many motorists have experienced the usual "hold up" by the police on our main roads and noticed the unsympathetic attitude of the walking public who stop to see the "fun." When the majority of motorists have experienced the methods of the police and the way in which the police are encouraged by magistrates against motorists in the police courts, we may hope for some concerted action, but, until we get to that stage, or enlist the aid of the daily press, we cannot hope for any relief from the present system of persecution. A. LONGMAN.

Sir,—In your issue of October 30th H. Reg. Jones states that "in this locality (South Wales) motor cyclists are watched in all ways, and on the slightest pretext are summoned and heavily fined," and that "no matter whether careful riders or otherwise, no one escapes for more than a month or so (in this locality at least)."

Now, while heartily agreeing with him that these Acts need well revising, as one of a motoring family of nineteen years' standing "in this locality," and as a motor cyclist of eight years, also "in this locality," I must take exception to these statements.

At all times we have found the police obliging and willing to help motorists. In at least six cases they have warned the owners of dogs which attacked me when on a motor cycle, and offered to take proceedings if the animals again offended.

As a matter of fact, most of them would welcome more sensible motoring laws.

I believe, if county records could be compared, it would be found that this county (Glamorgan) would head the list both for road improvements and non-molestation of motorists. Locally, if the police take action against anyone it is usually understood that the offender has been "asking for it." NELSON NEALE.

SPEED WOBBLE.

Sir,—As there have been several letters, etc., written in *The Motor Cycle* recently concerning "speed wobble," may I be permitted to advance a possible theory as to the cause of this phenomenon.

At high speed the front wheel of a motor cycle is subjected to a considerable force in a vertically upward direction as a result of the wheel striking the small irregularities in road surface. This force is aided, perhaps infinitesimally, by the pull of the engine on the back wheel, which tends to lift the front wheel.

The result of this is that after a certain speed has been attained, depending on the weight distribution in the particular machine, the front wheel is practically off the ground, and control becomes impossible.

This idea is based, and possibly confirmed, by the fact that a precisely similar wobble, increasing in width and finally finishing in a crash, can be produced at low speeds by weighting the carrier to a sufficient extent abaft the back axle.

A cure should lie in bringing the centre of gravity further forward.

Following this same line of thought, a quick rebound spring fork and a hard front tyre should make matters worse; hence an argument in favour of laminated front fork springs, with their nice lazy action. A.W.P.P.

On Active Service.

JET SIZES.

Sir,—I hope it is not too late to write a few words in reply to "C.T." in your issue of October 9th, which, as I have just come back from Egypt, I have only just seen. I had, until recently, a French military 3½ h.p. Sunbeam, with an Amac, and got the best results with a 26 jet. I found, however, that the marked sizes were very unreliable and confusing, but with this particular 26, and using benzole, I got 80 to 100 m.p.g. fairly slow running, and excellent hill-climbing.

I entirely agree with "C.T." about the air lever, and have found that with any jet only a small range of speeds is possible, without starving at high speeds and choking at low ones. The 26 jet gave an approximately correct mixture at about 20-25 m.p.h.

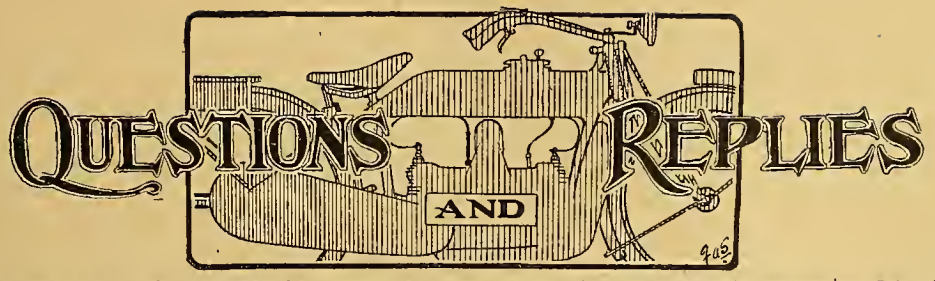
I should like to know if "C.T." or any one else has observed the following fact: With the engine running light and air about half open, the engine accelerated if the air was either fully opened or fully closed, but ran slower with the air lever in the middle. I should be interested to hear an explanation of this from the Amac people, or anyone else. I might also mention that I found it necessary to open the air at low speeds and close it at high ones, which is contrary to the makers' instructions. A. F. SCROGGS.

BOOKS AND MAPS FOR MOTOR CYCLISTS.

Issued in conjunction with "*The Motor Cycle.*"

	Price net.	By post.
"MOTOR CYCLES AND HOW TO MANAGE THEM." The standard handbook on the motor cycle—its care and management. Twentieth Edition. 286 pages. 400 illustrations ...	2/6	2/10
"HINTS AND TIPS FOR MOTOR CYCLISTS." Containing over 400 useful "wrinkles" and helpful hints in regard to motor cycles. Sixth Edition. (Second Reprint.)	2/-	-/-
"TRACING MOTOR CYCLE TROUBLES." A reliable system for tracing motor cycle faults and of remedying any trouble when found. Fourth Edition ...	2/-	2/3
"THE MOTOR CYCLE" ROAD MAPS. England and Wales, Scotland, London (showing roads into and out of London and avoiding London). Mounted on linen. Set of three, complete in case	4/6	4/10

Obtainable by post (remittance with order) from ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4, or of leading Booksellers and Railway Bookstalls.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Taxation Liability.

Will you please inform me if I am liable for Inland Revenue licence for a motor cycle which I bought in September this year, for which the previous owner had already paid the tax.—B.G.G.

If you used the machine in September, you are liable for the full tax, but if you did not take the machine on the road till October, half the tax is payable.

Sidecar for Lightweight.

I am the owner of a 2¾ h.p. (1915) A.J.S., and am desirous of fitting a light sidecar—not wicker—to my machine. It would be used chiefly for passenger work in the Cambridge district—flat country. I should be glad, therefore, to have your advice on the following: (1) best type of sidecar; (2) size of jet advisable; and (3) would any other alteration to the machine be necessary?—G.P.Y.

Your machine would be capable of taking a light sidecar and passenger in flat country. You would not require to make any special alterations to the machine, other than possibly fitting a larger jet in the carburetter. A 30 jet should be satisfactory. Most of the sidecar manufacturers make light coachbuilt sidecars.

Damaged in Transit.

I recently had cause to claim on the railway for an engine broken during transit to the makers. The engine was being sent for a minor repair, and when it arrived the fins were smashed off the cylinders. I was immediately advised by the makers. They, of course, renewed the cylinder, and this entailed new piston, connecting rod, etc., until their bill was £8 10s., which I paid. The railway company decline to recompense me, as the makers' employee gave a clear signature when the engine arrived. It was sent carriage paid, company's risk, and was externally perfect. Have I a case against the railway or against the makers?—W.A.L.

You are in rather an awkward position, as the makers gave a receipt clearing the railway company, and it seems to us that the proper course is to claim on the former for the damage through their negligence in giving this receipt, or else by arrangement with them to sue the railway company on the strict understanding that if the claim is lost through the receipt being given the firm will indemnify you from all loss.

Speed and Consumption.

On ordinary running, if the machine is travelling fast, does it use more petrol on the same length of run, or less, than when the speed is slower?—R.D.C.

All other conditions being equal, the petrol consumption is greater the higher the speed maintained.

For Overseas Condition.

Would you please inform me which type of motor cycle is best suited for overseas conditions in Palestine or Egypt?—C.H.T.

The most suitable type of motor cycle for the road conditions in Palestine or Egypt would be one with a fairly high ground clearance and transmission not likely to be seriously affected by sand or dust. A chain-cum-belt model would, therefore, be satisfactory, and the preference should be given to one in which the primary drive and all engine details are carefully enclosed. A cool running single-cylinder engine would be a desirable power unit.

CUMBERLAND M.C.C. (WESTERN SECTION) RELIABILITY TRIAL.

A. R. Hill (2¾ h.p. Royal Ruby J.A.P.) checking in at the finish. This rider lost only five marks on time, climbing Red Bank (Grasmere) and Kirkstone Pass (steep side from Ambleside) in fine style.

Engine Details.

Will you kindly answer the following? (1.) How are the valve guides fixed in a 1912 B.S.A. cylinder? (2.) How can I get them off? (3.) Would a piston ring that is $\frac{1}{32}$in. narrower than the groove in the piston cause knocking?—G.T.

(1 and 2.) The valve guides in the B.S.A. cylinder are a driving fit. To remove them they require knocking through. This must be done carefully so as to avoid breaking the cylinder. (3.) A piston ring so much undersize as your sketch indicates would certainly account for a great deal of engine noise

Oil Slinging.

(1.) My 3½ h.p. Rover has recently developed oil-slinging from the pulley side. Does this indicate engine wear? (2.) While running at 25 m.p.h. the steering seems to be affected slightly, giving the feeling of side-slip. On examining the engine I find I can move the main shaft horizontally about $\frac{3}{16}$in. by pulling the pulley. The belt now rubs against the silencer and the frame. The machine climbs beautifully, and there is no indication of knocking.—G.N.

(1.) This is probably due to wear in the main bearing. (2.) This might be due to the frame having been strained in some way. The side play you refer to may be ignored.

Silence.

Some time ago I purchased a 6 h.p. motor combination, but have sold it, mainly on account of its being so noisy and my wife's health not of the best. I should be glad (being quite a novice) if you would tell me: (1.) What are the chief causes of noisy motor cycles? (2.) What do you consider the least noisy make of motor cycle, capable of taking a heavily laden sidecar? (3.) Is a 3½ or 4 h.p. powerful enough to take a sidecar and passengers over any ordinary ground? Speed is of no consequence whatever.—Noisy.

It is impossible to say which is the quietest motor cycle on the market. Noise, of course, is largely dependent on the style of driving adopted, and there are many motor cycles at present on the market that are reasonably silent. We would advise you to study the figures in the reports of the 1919 Six Days Trial, when comparative tests were made in the silent running of the various competing machines.

Clutch Lining Material.

Could you please tell me which is the better lining for a clutch, leather or Ferodo?—F.W.

Ferodo is a most satisfactory lining, and has usually a much longer life than leather; it is less affected by external conditions, such as excess or lack of oil, heat, or undue friction by slipping.

Lack of Power.

I have a 4 h.p. Bradbury, old pattern (about 1909), with automatic inlet valve. It will work well on the stand, and starts easily, but after running twenty yards it has no power whatever. Can you tell me the cause of this? I find the inlet valve spring is very frail.—J.T.

Probably the weak inlet valve spring is the cause of your engine falling off in power. It may also be due to a partial stoppage in the petrol supply. You should notice when the engine stops whether the float chamber of the carburetter is empty; if so, try slightly raising the level.

Running Costs.

A friend of mine and I have been having a discussion as to the relative annual running costs of a twin motor cycle and sidecar and a light cycle car, say, of 8-10 h.p. We should like your opinion on this matter.—T.W.H.

With regard to the actual running costs, we do not think that there is any appreciable difference between those of a high-powered motor cycle and sidecar and a light car not exceeding 8 h.p. or 10 h.p. The expenses, however, involved outside running costs, such as garage, insurance, taxation, etc., are considerably higher in the case of the four-wheeled vehicle.

Two-stroke Troubles.

I have a two-stroke 2¾ h.p. engine—Dixie fixed magneto—as fitted to a 1914 Wolf. I have tried in vain to get this engine to fire correctly. Everything appears to be in perfect order. Sometimes the exhaust appears to be in the crank case, at others through the carburetter. A blow-back here is noticeable, even when the exhaust is *via* the correct port. The firing is only intermittent, exhausting at the points named. The spark is good. The piston rings are new. All joints are airtight. Jet No. 28, Amac. Compression not sufficient to lock the driving wheel. Piston after uncovering inlet port goes ¼in. higher. A thin machining has been taken off the neck of the crank case owing to a repair.—S.A.J.S.

The correct timing for your engine should be: Spark to occur with piston on top dead centre when the ignition control is fully retarded. Try a smaller jet, say No. 26. We do not think that a slight alteration to the crank case would seriously affect the running. A possible cause of the trouble may be that, in reassembling the engine, you have fitted the piston incorrectly; that is, with the deflector nearest the exhaust instead of having it on the same side as the transfer port.

Flat-faced Valves.

My engine is a single-cylinder 5-6 h.p. with valves faced on the under side of the head, instead of the usual petrol engine pattern. What is the advantage of valves faced in this manner?—H.D.

There is no particular advantage in flat-faced valves, and the few makers who favoured them have mostly discontinued their use.

Generosity may be Costly.

About two months ago I had the misfortune to run into a woman. It was quite an accident, as she and her friends admitted, and was entirely her own fault, for she said she completely lost her head. I took her home, and shortly afterwards called to see how she was going on. She said she was progressing nicely, but was still under the doctor. Later I received a note saying she was not going on so well, and the doctor advised her to write me and ask for assistance in the expenses that had been incurred. Unfortunately, I am not insured against third party risks, and therefore would like your advice what to do. The woman, who is not in very good circumstances, appears to me to be honest, and I should certainly like to help her in some way, but in these cases sometimes there is no end, and I thought if I made a payment I might incur further liabilities—C.B.

Under the circumstances you describe, any payment made by you to the party injured in the accident will seriously prejudice your position in the event of any legal action. Before offering any assistance, it would be as well to consult a local solicitor, or in any case to get an admission in writing that the accident was the fault of the other person.

EXPERIENCES WANTED.

"J.W.C."—Benefits derived from use of Spots in petrol on small four-stroke engine (Beaufort).

READERS' REPLIES.

Cutting Paper Washers.

In your issue of October 30th, on page 470, you have a short article describing how to make a paper washer for cylinder base. The method you give is, of course, very old, but the description is likely to give the novice some trouble. Instead of tapping round the outer edge of the cylinder base first, and afterwards tapping round the mouth of the cylinder, these operations should be reversed, the paper being held firmly while the circle of the cylinder mouth is tapped out. The paper will then be a tight fit round the lip of the cylinder, and will not move whilst the operator taps round the outer edge of the cylinder base and finally taps out the paper at the holes. The ideal tool for this job is a small ball-pane hammer. Personally, I make a dozen at a time by taking an impression or rubbing of the original washer and fastening to twelve pieces of paper cut to a suitable size, fastened together with paper stays. The outline of the washer is then cut round with a knife as used by embroidery draughtsmen who cut their designs out in paper or card. Thus in one simple operation I have enough washers to last a year or two. For those of your readers who are keen on a clean crank case, I would give the following tip. Well soap your washers on both sides before using, whether you oil them or not. There is no need to soak them in oil, which is a messy job, if they are liberally soaped.—F. W. CHAPMAN.

An Unsatisfactory Insurance Transaction.

Your answer is certainly not Scotch law, and is contrary to custom. Even if the average clause were contained in the policy and a machine insured for £80 stolen, although worth £100, the company would require to pay the £80 in full. The average clause would only come into play in the event of a partial loss. In the case stated, and presuming the machine was value for £100, you admit the insured was only four-fifths insured, but he is entitled to four-fifths of the total loss—£100; that is, £80 nett. His share of the loss, one-fifth, is represented by the difference between £80 and £100. Had the cycle been partially burned and the total damage £40, only then would the average clause come into play, and the insurance company would have stated they were prepared to pay four-fifths of the loss of £40, hand the insured £32, and make him pay the £8 himself. I have had many similar cases come up before me, and the above are the lines on which the companies have always paid.—INSURANCE AGENT.

CORRECT LUBRICATION

Mobiloils

A grade for each type of motor

STAND 141 MOTOR CYCLE SHOW OLYMPIA

AT Stand 141 in the Gallery at Olympia you will find the specified grades of lubricating oils for the Correct Lubrication of your mount—the one you now own or contemplate buying. The Lubrication Chart of Recommendations issued by the Vacuum Oil Co., Ltd., shows you the Correct Lubrication for summer and winter. Practically every make and model of motor cycle (from 1914 to 1919) is scientifically prescribed for.

TO the purchaser of a new motor cycle a timely word of advice is offered. When the engine is new it is naturally "stiff." The bearings and all frictional surfaces must adjust themselves to each other by *use*. That is one reason why motor cycle manufacturers emphasize so strongly the importance of Correct Lubrication.

TO be absolutely certain—to know without question—that you are doing everything possible to give your new engine its proper protection, fill up with the correct grade of Gargoyle Mobiloils at the start. And let the Chart of Recommendations be your guide; it is the recognised authority on Correct Lubrication.

"CORRECT LUBRICATION FOR MOTOR CYCLES—1919" is the name of a new booklet which may be had on request at our stand. The contents of this publication are highly interesting and instructive. Engine troubles are discussed and the causes and remedies given in simple language.

This booklet contains also our complete Chart of Recommendations. In this will be found the correct grade of oil for practically every make and model of Motor Cycle. Ask for your copy.

The GRADO MULTI GEAR

HERE is the very thing that motor cyclists have been wanting for years. A variable pulley that removes all the drawbacks of a Belt Drive on a motor cycle. A simple contrivance that gives to the motor cyclist advantages which were hitherto available only to the car owner.

THE ADVANTAGES OF FITTING——

The GRADO MULTI-GEAR with Free Engine.

YOU CAN forget your belt. However slack it is there will be no slip—the pulley sees to that.

YOU CAN start your machine from a standstill—just like a car.

YOU CAN tackle the steepest hills with confidence, even with a fully loaded sidecar—the Grado gives you a range of gears from 4—1 to 8—1 for machines of 3½ h.p. to 6 h.p., and 10—1 for lightweights.

What It Does:

Starts your machine like a car!

Takes your machine and sidecar up hills impossible without!

Gets you safely through thickest traffic!

Ensures safety over greasiest roads!

In fact, it turns work and danger into a pleasure.

Just half a turn of the handle on top tube changes from top gear to free engine!

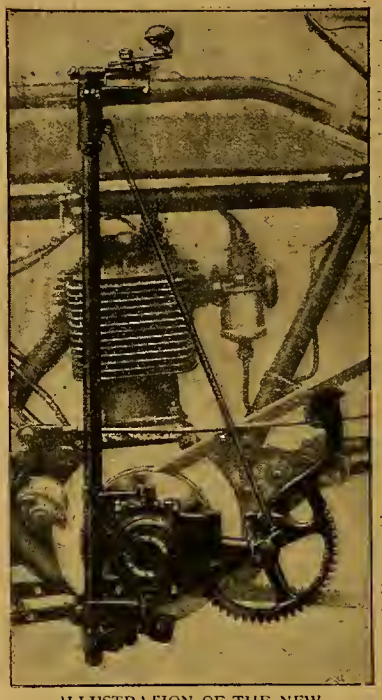

ILLUSTRATION OF THE NEW

KICK-STARTER MODEL.

Can be fitted by any rider in 2 hours to Brad burys, Triumphs, Precision, B.S.A., T.D.C. Nortons, etc.

Prices for Kick-Starter Model: For machines up to 6 h.p. £11 0 0, Special Model for J.A.P. and Minerva Engines, etc, 10/- extra, postage 3/-.

Prices for Ordinary Pulleys less Kick-Starter: For machines up to 4 h.p., £7 10 0. For machines up to 6 h.p. £8. Recess Pulleys for J.A.P. and Minerva Pulleys. 10/- extra.

Prices for Lightweight Pulleys, less Kick-Starter: For machines up to 2¾ h.p., £6 0 0. Postage, 2/-.

Delivery now about Seven Days subject to strikes and lock-outs

YOUR PLEASURE IN MOTOR CYCLING WILL BE DOUBLED

STAND 31

A·J·S
—the incomparable.

The merit of the A.J.S. is not confined to any particular part or feature—it is of all round superiority.

It is the outcome of ambition, enthusiasm and scientific expert knowledge—the culmination of a desire to produce the Passenger Outfit—incomparable.

And that we have attained our object is proved by the universal recognition and acknowledgment of A.J.S. superiority, and the remarkably high percentage of awards gained in Open Competitions.

The A.J.S. is made throughout at our own Works under the strictest supervision during manufacture and erection, and its correct design, mechanical perfection, and embodiment of every modern convenience and improvement, make it a masterpiece of BRITISH engineering skill and thoroughness.

You can examine the A.J.S. at your leisure at Stand No. 31 at the Olympia Cycle and Motor Cycle Show—be sure and do so.

Fullest information and latest catalogue however may always be obtained on application to

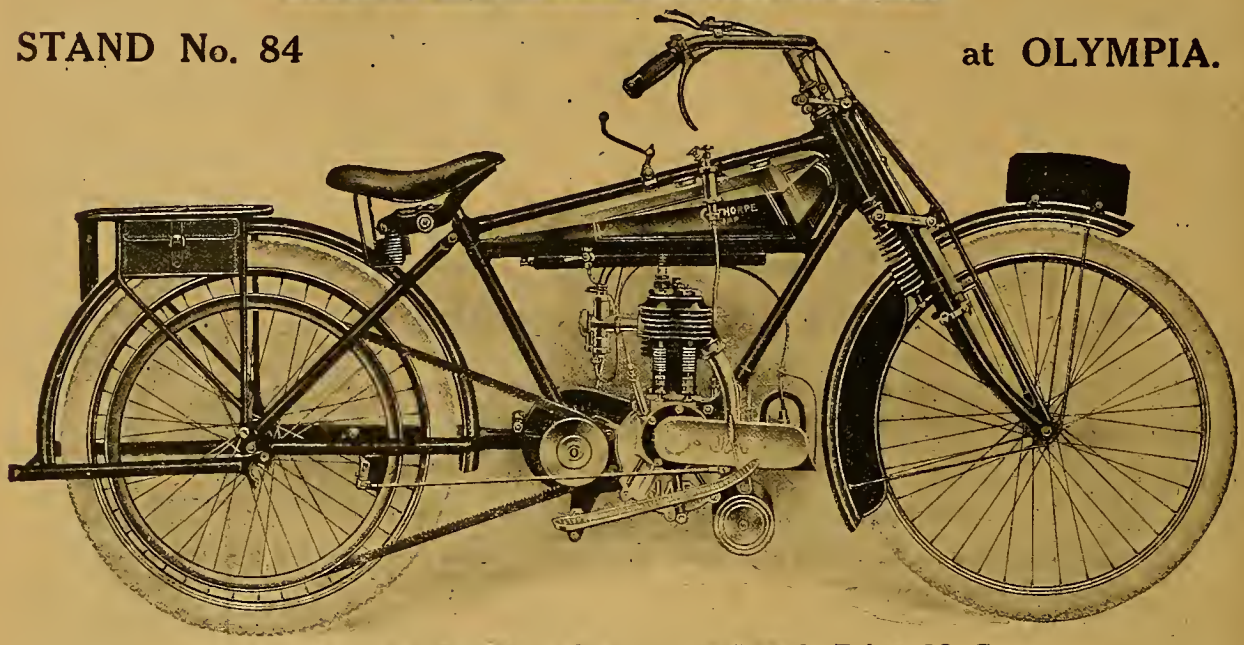
CALTHORPE

The Little Mount for Big Events.

STAND No. 84 **at OLYMPIA.**



The CALTHORPE-JAP 2¾ h.p. Two-Speed. Price 60 Gns.

The Calthorpe-Jap is the model usually chosen for heavy and strenuous work—fitted with Jap Engine and Enfield Two-speed Gear, as high-powered speed unit, it embraces all that is highest in Motor Cycle Construction.

SPECIFICATION.

ENGINE. 2¾ h.p, Jap. 70 mm. × 76 mm. bore and stroke, 292 c.c. A fast and powerful engine. All bearings are of a special alloy of Phosphor Bronze cast under pressure to secure great hardness. The valves are of special material and made from the solid bar to secure uniformity of material.

TWO-SPEED GEAR. The Enfield Patent Two-speed and Free Engine, with cush sprocket

CARBURETTER. Improved pattern, Amac.

IGNITION. High-tension variable Magneto, handle-bar control.

TANK. Very strong, of registered design, enamelled Black and English Gold Leaf lined, fitted with new Best and Lloyd's sight-feed lubrication. Capacity 1¼ gallons petrol, 1 quart oil.

TRANSMISSION. Two roller chains (on the left hand side of the machine) from sprockets on the engine shaft, one from each gear to a counter shaftin the bottom bracket, which contains the two-speed mechanism. The drive from the countershaft to the back wheel is by ¾in. belt off a fixed pulley on the right hand side of the machine. Midway between the two gears is the free engine position, which is passed through to engage either gear. The drive through both gears is direct, thus obviating that friction which is created when running through gear wheels.

FRAME. Built of the finest Weldless Steel Tube throughout, all vital parts reinforced, and complete with Druid Girder spring forks.

WHEELS. 26in. × 2in. Dunlop Beaded Edge Studded Tyres, heavily plated steel rims with coloured centres, oil retaining dust and weather proof hubs.

BELT. ¾in. Dunlop.

BRAKES. Rear acting on belt rim, operated from foot pedal and powerful Bowden front brake.

SADDLE. Patent Pan Seat, Gough or other make at our option.

COMPLETE. With stand, carrier, strong wide mudguards, armoured Pannier Bags, with tools in roll complete, handsomely finished in four coats of lustre enamel and all bright parts heavily plated.

We reserve the right to deviate in minor details from the above specification.

The "IVY" TWO STROKE

We would make it better if we could.

We won't make it better because we can't.

The above few words sum up our whole policy. Every time and all the time we are out to produce a motor cycle of distinction, an aristocrat among its fellows, and we invite you to visit our exhibit

On STAND

No. 91

when we shall have pleasure in demonstrating to you the various features of design, all of which go to make the machine THOROUGHBRED.

S. A. NEWMAN, LTD., ASTON CROSS, BIRMINGHAM.

DRUID
Efficiency.

In the huge demand we are experiencing for the DRUID Spring Fork, and in our present inability to execute orders with our usual promptitude, the observant motor cyclist can read the secret of the DRUID'S popularity—Efficiency.

We much regret the enforced delivery delays, and crave the indulgence of our many waiting customers.

All sent carriage paid in sections.

Sutcliffe's Motor Sheds are the strongest built, best designed Motor Sheds you can get at anything like the price; don't be tempted to buy weakly constructed Sheds, they are most expensive in the end. Study Sutcliffe's Construction:—Sides, ends, roofs built on ¾-inch best match boards, roof also covered with extra heavy felt, rainproof, framework of tremendous strength. All floors are double strength, will carry a ton or more weight easily. All houses erected and bored before despatch, all bolts supplied free. If any client is not perfectly satisfied, simply return shed and we refund purchase price. Full details in free booklet. Can rail any size in 2 to 6 days.

F. & H. SUTCLIFFE, 44, Wood Top, Hebden Bridge, Yorks. *'Phone:—58, Hebden Bridge.*

Easy Payment Terms.—All these sheds can be had on easy payment terms through our agents, Messrs. J. G. Graves, Ltd., Sheffield. Those who wish to buy this way kindly write Messrs. Graves for their terms.

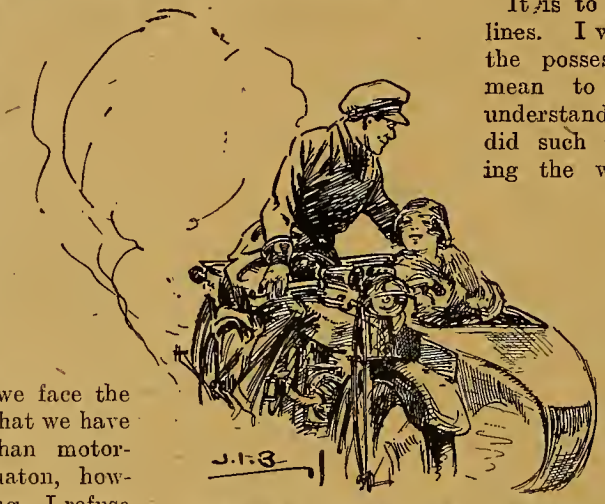
If you are unlucky and are not able to visit Olympia, read the pages of this issue carefully as the best alternative. They constitute Olympia in a nutshell.

WHY YOU SHOULD BE A MOTOR CYCLIST

THE first Olympia Show since the war is the beginning of a new era in the history of motor cycling. Five years ago pessimists were croaking that the war would be the death of the sport; to-day we realize that nothing has done so much to popularize motor cycling as the great struggle through which we have passed victoriously.

Tens of thousands of men and women have learned to drive during the war; hundreds of thousands who had never before been driven in sidecars have learned by practical demonstration the value of these speedy and economical little outfits. To-day we face the curious position of finding that we have far more motorcyclists than motorcycles. This peculiar situaton, however, is not likely to last long. I refuse to believe that a country that could perform the engineering miracles that were worked during the war can be beaten by any difficulties, and I look forward to a time in the near future when there will be ten motorcycles on the roads of Great Britain in the place of every one that raised the dust before the war.

At this great Show there will be thousands of men and women who have never yet owned motorcycles but who have been made to realize their utility during the last five years, and who do not require very much persuasion to induce them to join the ranks of those who motorcycle for pleasure.



"Those who have not experienced the pleasures of sidecarring can hardly be said to have lived."

It is to these that I address these lines. I want them to realize what the possession of a motorcycle will mean to them. I want them to understand that the machine that did such faithful donkey work during the war is in peace time the greatest boon that has been given to us by science.

The possession of a motorcycle changes all one's views of life. It is not merely a means of locomotion; it is a constant source of new pleasure; it provides a new sport; it appeals to both sexes and to the elderly as much as to the youthful.

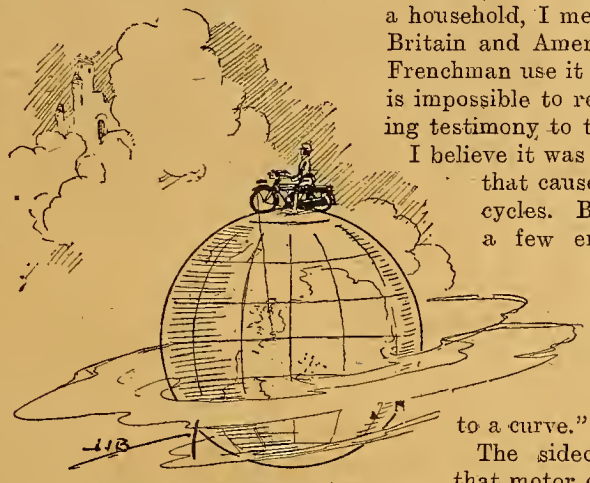
Many are at first attracted by the obvious utility of the machine. They think it will be useful for business purposes, which it will be without doubt, or that it will serve to take them to the river, the football field, or the tennis club. One and all they learn that the pleasures of motor cycling lure them from the aforetime fascinations of inferior sports.

"With a motorcycle you can start off in the morning tor the links. . . . ."

Why You Should be a Motorcyclist (contd.).

Those who have patiently patted a white globule round the same old golf course year after year and have cursed in the self-same swear words in the same old bunkers and over the same old rabbit holes, suddenly realize that there are other courses to conquer. They make new friends; life is broadened. Soon the fascination of travelling outweighs all other pleasures; the motorcycle is no longer regarded merely as a means of getting about, but as a creature that is palpitatingly alive.

Most things mechanical add to the irritations of life. Trains mean boredom from which we drug ourselves by reading papers that only bore us a little less; the time-wasting invention of the telephone has caused more enthusiastic profanity than any other device of man, always excepting those hideous burrowings into the home of the earthworm in which Londoners hang by straps over seats for which they have paid.



With a motorcycle the world is yours to explore.

But a motorcycle is a thing that every normally-constructed man or woman can love. To begin with, it pleases the eye. It is graceful in its lines. It arouses one's intelligent interest. One wants to know all about it. It has moods that have to be humoured as a lover—poor brute—humours the whims of his pro tem. inamorata. But unlike the lover of woman, he who gives his affections to a motorcycle has the satisfaction of knowing that its whims are understandable, whereas——. But enough has been said. I am reminded that *Motor Cycling* has many readers of the sex that so charmingly adorns our sidecars.

One of my few claims to fame when I am declutched from this life, and of which I wish to remind obituary writers, is the invention of that terminological exactitude the "Flapper bracket" which first appeared in *Motor Cycling* some six or seven years ago, and which, like "Gipsy Meeting," has become a household, I mean roadside, word in Great Britain and America. I have even heard a Frenchman use it with a pronunciation that it is impossible to reproduce, a somewhat striking testimony to the ubiquity of this journal.

I believe it was the invention of the sidecar that caused the great boom in motorcycles. Before that time there were a few enthusiasts, some of whom hitched trailers to their machines, and inspired *Punch* to the famous picture of a motorcyclist calling out to an empty trailer, "Hold on tight, Auntie, we're coming to a curve."

The sidecar removed the objection that motor cycling was a selfish and unsociable pastime. Young men should be warned that the possession of sidecars makes it extremely difficult for them to avoid the careless habit of becoming engaged.

Those who have not yet experienced the pleasures of sidecarring can hardly be said to have lived. To set off early on a summer morning with a congenial friend who knows how to "do" her hair so that the

. . . play your two rounds without worrying about having to catch a train at any particular time, . . .

". . . and return home in the evening to your front door, saving yourself a walk from the station."

wind will not disturb it and put her out of temper, and to leave cities and work behind, to get out into God's own country, along roads tunnelled through trees and flecked with sunshine, to rush through pure air over commons flecked with white geese, past purple heaths, over wooded hills and open moorland, is an experience once enjoyed will never pall.

The need for alertness when driving to avoid the dangers of the road produces a pleasant stimulation of the senses that banishes all cares. One is merely conscious of a feeling of supreme happiness. Scenes change so rapidly that the fascination is never dimmed, and always the white ribbon of road lures one on to find out what lies round the next bend, or what view will be disclosed when the summit of the next hill is reached.

Other sports may thrill, but motor cycling gets into the blood; it arouses the wanderlust that can never be sated. It gives one the feeling that at least one has discovered what it is to be free. Instead of a garden, one has counties to play in, or countries or continents if time permits.

And the desire to explore, to see how God has planned his great garden, becomes keener as time goes on. One-day runs to the country and the sea are extended into long week-end tours covering hundreds of miles, and still the ambition to go farther afield grows steadily. Arrangements are made for a holiday tour. There is no need to decide upon where to go. The wise man does not make plans of any sort. He has all of Great Britain to play in, and the whim of the moment will determine where the next resting place shall be.

The owner of a modern motorcycle has a machine that will take him to worlds of romance of which he has formerly only dreamed. He may have it slung aboard a Channel steamer and the Continent of Europe is his to enjoy. The chateaux of France mellowed by the glamour of history, the sunshine of the Mediterranean, the white Alps that glow crimson as the sun sinks, the valleys of Switzerland painted with gentians and Alpine roses, lakes, waterfalls and glaciers that are frozen oceans of lovelier blue. Italy! He may learn all that her name means to her lovers; Spain with its memories of Moorish grandeur, its colour and sun—as time goes on he may know all these as no tourist who is the slave of railways can ever know them.

Remember that when one has bought a motorcycle one has a key to the world. It costs no more, very often less, to spend a motor cycling holiday exploring Europe than to spend it in England.

If you were given a free pass over all the railways of Europe would you not travel? If you would not you must be strangely lacking in that spirit of adventure that has made Britain. The motorcycle is a travelling pass to the lands of which you have read and about which you have dreamed on so many occasions.

And let me tell you one thing more. If you buy a motorcycle to-day you will find that it is an introduction into the society of the keenest, most human, most chivalrous sportsmen and sportswomen in the whole world.

Join them now and may the best luck of the road be with you!

Competitions for 1920.

A MEETING of delegates from each of the territorial districts in which the Motor Cycling Clubs have been divided by the Auto-Cycle Union, will be held at Olympia at 5.30 p.m. to-morrow, Thursday. This meeting is principally being held for the purpose of arranging dates for the more important competitions in 1920.

C22

Many Cyclists Fined.

IT is interesting to note that, in connection with the tirade against rear lamps, no fewer than 50 cyclists were recently fined 10s. for omitting to carry a rear light. A representative from The Cyclists' Touring Club attended in order to endeavour to get the convictions quashed, but his efforts were naturally unsuccessful.

Cycle and Motorcycle Show.

NEWS IN BRIEF.

Lighting-up Times for Saturday, November 29, 1919.

London	4.25 p.m.	Edinburgh	4.16 p.m.
Newcastle	4.20 p.m.	Liverpool	4.30 p.m.
Birmingham	4.29 p.m.	Bristol	4.35 p.m.
Dublin	5.13 p.m.		

Lighting-up time in the United Kingdom is now half-an-hour after sunset. Lamps must be kept alight until half-an-hour before sunrise. Moon.—First Quarter 30th.

A Spartan Rider.

THE defendant in a recent speed limit case gave the novel excuse that the bumpy road caused him to go faster than he meant to. One is tempted to ask—twist grips or levers?

Death While Driving.

AT Birkenhead recently a driver of a sidecar outfit with a lady passenger, collapsed in the saddle. He was picked up unconscious and died immediately. Apparently his last act was to close the throttle, and the machine came to a standstill within a few yards.

Interesting Engine Developments.

WE have often wondered how long it would be before the sleeve valve made its appearance in motorcycle engine practice. We now hear rumours of a most interesting single-cylinder engine being built in the north, and which has already undergone some very extraordinary tests most successfully. In its present form the engine is of quite small dimensions, being but 70 mm. by 76 mm., but it has shown such promise that its builders are already embarking upon a large range of models, running as high as 7 h.p.

To T.T. Aspirants.

READERS will remember a paragraph which recently appeared, stating that a well-known concern was anxious to get in touch with a possible rider for next year's T.T. race. The result was an avalanche of applications, and we are now asked by the concern interested to say that, while every application is receiving consideration, it is, of course, impossible to reply to each one individually.

Triumph Finance.

ONCE again the Triumph Co. have had a prosperous season. The directors recommended at the 24th ordinary general meeting of the company, held on the 28th inst., that a final dividend at the rate of 12½ per cent. be paid on the ordinary shares, and 6½ per cent. on the preference shares. These two dividends will account for a sum of £31,137 10s.; £25,000 will be carried forward to the general reserve fund, while the pension fund, which has been especially for the benefit of the employees of the company, will be increased by £2,000. In addition, the amount of £13,284 12s. will be carried forward to next year's account. During the year the company has lost the services of Mr. M. J. Schulte, who was the joint managing director and one of the founders of the company. Mr. Schulte has retired from business altogether.

Royal Ruby Developments.

IN order to cope with the demand for Royal Ruby motorcycles and to increase their output, the Ruby Cycle Co., Ltd., have now taken over a works at Altrincham for the manufacture of their 3 h.p. machine.

CAUGHT AT THE RIGHT MOMENT.

"Unfaked" photographs of spills taken at the psychological moment are rare. These two falls were experienced during the recent Scott trial and we are indebted to the Gaumont Film Co. for permission to reproduce the photographs.

Prices, Deliveries, and Horse-powers—The I.A.E. and the Six Days' Report.

Royal Ruby Price.

AT the time of going to press with the article which appeared in our last issue there was some doubt concerning the price at which the new 3 h.p. spring frame Royal Ruby would be sold. We are now advised that this has been fixed at 95 guineas.

The Regent Delivery Position.

WE fear that perhaps the wrong impression may be conveyed through a phrase which appeared in the description of the Regent motorcycle in our last issue. We said that deliveries might be delayed "owing to the extensive tests that had to be carried out." We are now advised that there are no further tests to be undertaken, as the producers have already satisfied themselves as to the thoroughness of the design.

The I.A.E.

A SPECIAL meeting for the purpose of discussing the judges' report on the recent Six Days' Trial will be held in the top room of the Princes' suite at Olympia at 2.30 p.m. on Thursday afternoon next, the 27th inst. The meeting is open to all interested in motoring matters, and it is hoped that there will be a large attendance of the manufacturers who entered machines in the Trials.

The 1920 T.T. Limits.

WE learn that at the last meeting of the Competitions Committee of the A.-C.U., the basic conditions of the 1920 Tourist Trophy Races were discussed. It was proposed by Mr. A. V. Ebblewhite, seconded by Mr. E. B. Ware, and carried unanimously, "that two Tourist Trophy Races be held in the Isle of Man, a senior race for machines not exceeding 350 c.c., and not over 200 lb. in weight, and a junior race for motorcycles not exceeding 250 c.c. and 125 lb. in weight." The reduction in capacity in the two classes is due to the fact that 500 c.c. machines were becoming too fast to be safe on the island roads.

A SIDECAR BODY FOR DUCK SHOOTING!

Our American correspondent, having first sealed up all body joints with pitch, successfully used his sidecar body as a duck punt.

A Regrettable Accident.

READERS will be sorry to hear of an unfortunate occurrence to Lieut.-Colonel Charles Jarrott, the popular president of the Motor Cycling Club. A few days before the Car Show opened Colonel Jarrott had the misfortune to cut his foot on a broken bottle. The wound proved to be more serious than was at first anticipated, and eventually he had to enter a nursing home, where an operation was performed. We are glad to hear that he is now progressing favourably, and that we may expect to see him amongst the visitors to the Motor Cycle Exhibition.

D2

The New Humber Model.

IN our description of the 1920 Humber last week, we inadvertently referred to the new 4½ h.p. model. The capacity of its cylinders is 600 c.c., so that it will be at once seen that its power is considerably more.

Lecture at the R.A.C.

READERS are reminded that a lecture on "The 1919 Olympia Show" will be given by Mr. Douglas Leechman at the Associates' Room, R.A.C., Pall Mall, on December 4th next, at 7.30 p.m. The Essex M.C.C., under whose auspices the lecture is being given, extend a hearty welcome to all.

MIDLAND CLUBS AND 1920 COMPETITIONS.

FOLLOWING on a meeting, held in Birmingham a week or so ago, to consider the question of amalgamation of the Birmingham clubs, at which meeting it will be remembered the clubs decided not to amalgamate entirely just yet, but to amalgamate for the purpose of open trials, a meeting was held on Monday, the 17th inst., to which meeting all the clubs included in the Midland District under the new A.-C.U. scheme were invited.

Mr. Frank Urry, the hon. secretary pro tem. of the Midland Centre, was asked by Major Vernon Brook, who was elected to the chair, to read the correspondence he had received from the clubs not represented. The Wolverhampton Club had been written to several times, but had not replied to the letters, and the Banbury and White and Poppe Clubs were evidently not sufficiently interested to be present. Representatives were present from the following clubs:—

Birmingham M.C.C.
Sutton Coldfield A.C.
South Birmingham M.C.C.
Midland Cycling and Athletic Club.
Redditch and District M.C.C.
Kidderminster M.C.C.
Nuneaton and District M.C.C.
Clarion M.C.C.

The Chairman, after explaining the objects of the meeting, said he hoped it would be possible to come to an amicable settlement as to which clubs or group of clubs would have the four A.-C.U. open competition permits for 1920 allotted to them, otherwise the matter would be left in the hands of the A.-C.U., who would have to ballot for the names of the clubs.

Mr. Murray, of the Clarion M.C.C., proposed that the whole of the clubs should amalgamate for the purpose of running four good open trials.

Mr. C. Dawes, of the M.C. and A.C., Mr. F. S. Whitworth, of the Sutton A.C., and other speakers were opposed to this on the ground that by the time the third or fourth trial came round the officials would be so tired of their jobs that the events would be more or less moribund. They also pointed out that a spirit of friendly rivalry was necessary if competitions were to be kept up to the high water mark of efficiency and organization, and if all four trials were in the hands of one group of officials there would not be this spirit of rivalry and sportsmanship.

Before the proposition was put, it was suggested that the Redditch and Kidderminster Clubs, who had already expressed their willingness to amalgamate, should combine with the Wolverhampton Club and be allotted one of the four permits, this suggestion being agreed to by the Redditch and Kidderminster Clubs, the Wolverhampton Club not being represented. Mr. Dawes moved as an amendment to Mr. Murray's proposition that those clubs desirous of obtaining an open trial permit should hand in their names, and the whole meeting would ballot for the three most likely clubs, not including the three above mentioned. The amendment, being put, was carried.

The following clubs applied for permits:—Birmingham M.C.C., Sutton A.C., South Birmingham M.C.C., M.C. and A.C., and the Clarion M.C.C.

These names being put to the vote, the count came out as follows:—

M.C. and A.C., 13 votes.
Birmingham M.C.C., 12 votes.
Sutton Coldfield, 12 votes.
South Birmingham, 5 votes.
Clarion M.C.C., 3 votes.

South Birmingham and the Clarion M.C.C., therefore, drop out of open trials along with the other clubs which did not apply, during 1920. It was decided that in the event of a fifth permit being granted to the Midland centre, as was considered by the meeting very essential, in view of the importance of the Midlands, not only from the strength of its Clubs, but also as a motorcycle manufacturing centre, then the South Birmingham M.C.C. would take it.

The meeting then unanimously elected Major Brook as delegate to the meeting of clubs to be held during the motorcycle show, and gave him a mandate to ask the A.-C.U. to confirm the decisions made regarding the allocation of permits, and not to grant permits to any of the clubs which did not attend the meeting, but which might apply for them on their own initiative. The meeting also was strongly of the opinion that the distribution of permits had been very badly carried out, in view of the importance of the centre with its 11 clubs, compared with the north-western district with only four clubs, which was allocated three permits, and the delegate was instructed to apply for an additional permit at the Show meeting, which takes place this week.

THE MANUFACTURERS' UNION BANQUET.

Great Gathering of the Trade and Press—Interesting Statements Made.

THE fifth annual banquet held by the Cycle and Motor Cycle Manufacturers and Traders Union, Ltd., took place at the Criterion Restaurant last Friday, and was eminently successful.

The chair was taken by Mr. C. A. Hyde (of the B.S.A. Co., Ltd.), who is now resigning from the position he has held on the Union for three years. Practically all the leading men in the cycle and motorcycle industry were present, together with a very representative gathering from the Press, both technical and daily, who listened to the speeches with great interest. After the toast of "The King," which was proposed by the chairman, Mr. E. Manville, M.P., President of the Associated Chambers of Commerce, proposed the toast of the Manufacturers' Union, to which Mr. Hyde replied with some very interesting remarks concerning the state of the industry. The guests were toasted by Mr. A. Brampton, J.P., and in response Lt. Col. Sir Rhys Williams, Bart., in discussing future road extensions, made public a sugestion for special tracks for cyclists. The toast of the guests was replied to in addition by Sir Allan Smith, K.B.E., and by Mr. Massac Buist on behalf of the Press. The chairman was toasted by Mr. Harold Bowden. It is regretted that we have not sufficient space to report more fully the speeches, but the more interesting topics discoursed upon are dealt with editorially this week.

D3

MOTOR CYCLING

The Original Motor Cycling Journal. Founded in 1902. New Series Commenced 1909.

Written, Edited and Illustrated by a Staff of Practical Motor Cyclists.

Conducted by EDMUND DANGERFIELD.

Proprietors—TEMPLE PRESS LTD., 7-15, ROSEBERY AVENUE, LONDON, E.C.1.

The Manufacturers Agree with Our Views.

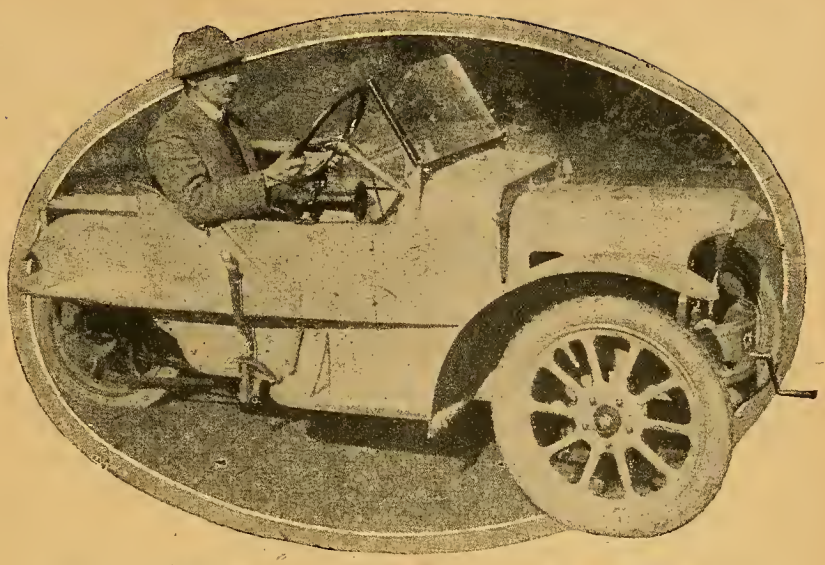
At the fifth annual banquet of the Cycle and Motor Cycle Manufacturers and Traders Union, Ltd., naturally the favourite topic in the speech-making was the state of the motorcycle industry. It is gratifying to note that, in the speeches made by the chairman and others present, many of the subjects we have discussed and suggestions we have made editorially during the past year were brought up, and our views generally were agreed upon. It will be remembered that a month ago we prophesied that the prices ruling when the Olympia Exhibition opened would be even higher than they had been in the past. The price question was very fully dealt with in the speeches, and it was pointed out that as the price of the motorcycle is not advanced to anything like the same extent as the increased production costs, the motorcycle to-day in comparison with other commodities was really cheap. It is gratifying to note that the members of the Manufacturers' Union realize that no useful purpose is served by the "cut-throat" policy, and they intend in the future more than ever to work together and exchange opinions, all of which will help towards producing better motorcycles and more of them. In this connection a committee composed of ten members from some of the leading manufacturers is now thoroughly going into the question of cost. Another point touched on in the speeches was that of Overseas trade, and again the views we have been expressing periodically for the past year were agreed upon. It is pointed out that British trade abroad was being very severely handicapped owing to our manufacturers being unable to produce sufficient machines for our home markets, and consequently making no attempt to capture, or even to hold their own in, the foreign markets. It was urged that all manufacturers should make a point of setting aside at any rate a small percentage of their output for export, in order that our Colonies and foreign countries should not have a chance to forget that the British made machine is the best of them all. If no British machines are exported, all the export trade will go to foreign markets, whereas if even only a few English machines are sent abroad, it will form the starting point of a great export trade, when production makes this possible. The Secretary to the Minister of Transport in conversing upon road alterations stated that a proposal had been made for providing specially-prepared tracks for cyclists. We are of the opinion that it would be moving more with the times if special roads were set apart for motor vehicles

The Need of a Special Exhibition Building.

We are writing before the doors of the Cycle and Motor Cycle Exhibition are thrown open to the public, but do not hesitate to prophesy that the attendance will be almost, if not quite as great as in the case of the recent Car Show. Those who visited the latter will agree that the crush at all times was so great as to defeat to a great extent the primary object of the exhibition, i.e., facilitating the examination and comparison by the public of a number of competitive makes of machines. The growth of the popularity of all species of motoring is rapid, and with every prospect of a "boom" season in front of us, it does not require a very vivid imagination to conclude that Olympia will not be able to cope with the crowds which will seek admittance to the 1920 Exhibitions. It is, of course, impossible to find a cure within twelve short months, but the obvious solution, in our opinion, would be the erection in some public park of a building of sufficient size to house the largest exhibition—be it of a motoring or any other nature—likely to be held for many years to come. It should be an exhibition hall, pure and simple, and it should be possible and desirable to incorporate with it open spaces in which demonstrations under working conditions could be held, and—in the case of both the car and motorcycle Shows—a gradient on which hill-climbing powers could be demonstrated. Utopian, perhaps, but feasible, and, if only desirable at present, certainly imperative in the immediate future. First cost would, of course, be heavy, but it is a characteristic of the "nation of shopkeepers" to encourage exhibitions of all kinds, and there should be no doubt that such an institution would be self-supporting. The enormous crowd which will be present at the Motor Cycle Exhibition will prevent many from viewing the exhibits as carefully as they would wish. In order partly to do away with the confusion resulting from sightseers trying to push in all directions, irrespective of any "rule of the road," we have suggested to the Manufacturers' Union that some system of traffic control should be instituted. The idea is to allow traffic in one direction only along each gangway. This could be effected by the use of arrows, whilst the stationing of R.A.C. Guides or A.A. Scouts at each corner for the purpose of controlling the traffic would be of considerable benefit to all concerned. The suggestion has been very favourably received, but unfortunately it has been made rather late, and it is therefore doubtful if the necessary arrangements can be made in time to carry it out.

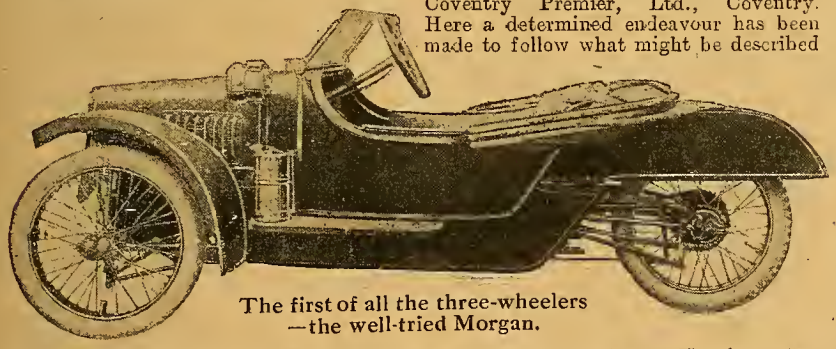
THE GROWTH OF THE THREE-WHEELER.

New and Interesting Examples of Light Runabouts.



The L.S.D., which sells for £185—the cost of a first-class sidecar outfit.

DESPITE a good deal of prejudice, the light three-wheeled type of runabout has made remarkable strides and bids fair to be one of the most popular types of cyclecars on the market. In the past there has been a great deal of misconception regarding three-wheelers, and its removal is due, in no small measure, to the unwavering zeal shown by the manufacturer of what must be regarded as the most successful three-wheeler of the day, viz., the Morgan. No apology, therefore, is necessary in dealing with this car first.



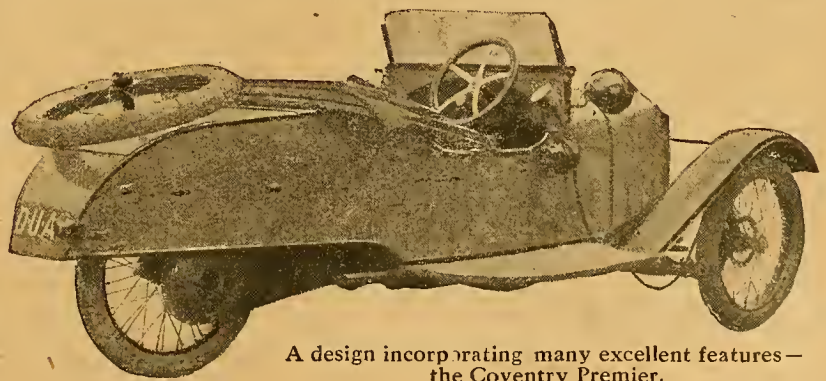
The first of all the three-wheelers —the well-tried Morgan.

The Morgan will be exhibited on Stand No. 120, and, although its chief characteristics no doubt are familiar to readers of *Motor Cycling*, a brief survey of the specification may be given. The power unit is an 8 h.p. J.A.P. twin, either air or water cooled, the carburetter being an Amac. The drive is transmitted through a cone clutch lined with Ferodo to a bevel box through the medium of an enclosed propeller shaft, the final drive being obtained by means of dogs and chains to the rear wheel. Helical suspension is provided for the front wheels, whilst double quarter-elliptic springs are fitted at the rear. Noteworthy features are the fitting of oversize tyres (i.e., 700 mm. by 80 mm.), and the sturdy design of the band brakes, which act upon drums forming part of the rear wheel. The overall length is 9 ft., overall width 4 ft. 7 ins., and the chassis weighs about 2¾ cwt. Steering is direct. The prices of the Morgan range from £145 for the sporting air-cooled model to £160 for the water-cooled De Luxe, the address of the manufacturers being The Morgan Motor Co., Ltd., Worcester Road, Malvern Link.

A three-wheeler which is bound to attract a good deal of attention is the Coventry Premier, which is made by Coventry Premier, Ltd., Coventry. Here a determined endeavour has been made to follow what might be described as light car practice, a V-twin water-cooled engine being installed within a car-type bonnet, and cooling being effected by means of a handsome radiator in the orthodox position. Beneath the radiator is found the starting handle, which is not placed at the side as in the case of the Morgan. A leather inverted cone clutch takes the drive by means of a shaft to a neat gearbox, which gives three forward speeds, and what is distinctly an innovation as regards the three-wheeler—a reverse. The final drive is by enclosed chain. Reduced steering is provided by means of a rack and pinion, whilst springing is by quarter-elliptics throughout. The Coventry Premier will be shown on Stand No. 62, the price completely equipped with three lamps, generator, spare wheel and tyre being £210.

The third type of three-wheeler having final chain drive is the L.S.D., which will be exhibited on Stand No. 38, and is priced at 185 guineas. The general trend of design somewhat resembles the Coventry Premier, inasmuch as a gearbox is employed, the final drive being by means of shaft and chain. The engine, however, is an air-cooled J.A.P., whilst the gearbox only provides two forward speeds and a reverse. A patented system of suspension of the helical type, and probably very similar to the Morgan, is employed at the front, whilst quarter-elliptic springing is used at the rear. The L.S.D. also resembles the Morgan in so far as steering is concerned; this is direct. A refinement is provided by the electric lighting, which we understand to be a standard fitting, whilst the equipment includes hood, tools, etc. The car is manufactured by Sykes and Sugden, Ltd., Spring Place Works, Huddersfield.

Only one variety of three-wheeler

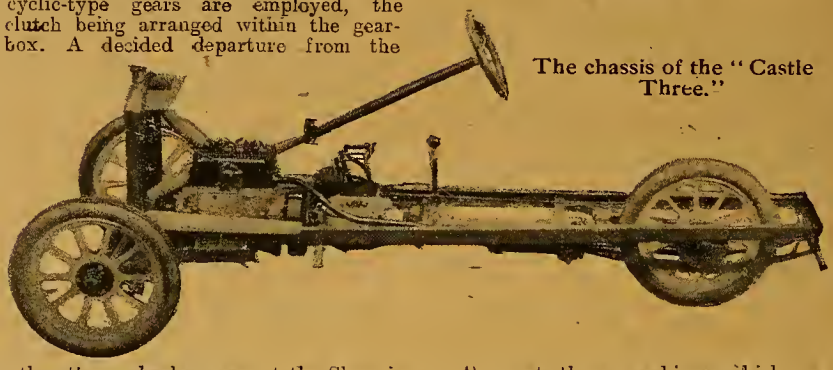


A design incorporating many excellent features—the Coventry Premier.

Growth of the Three-wheeler (contd.).

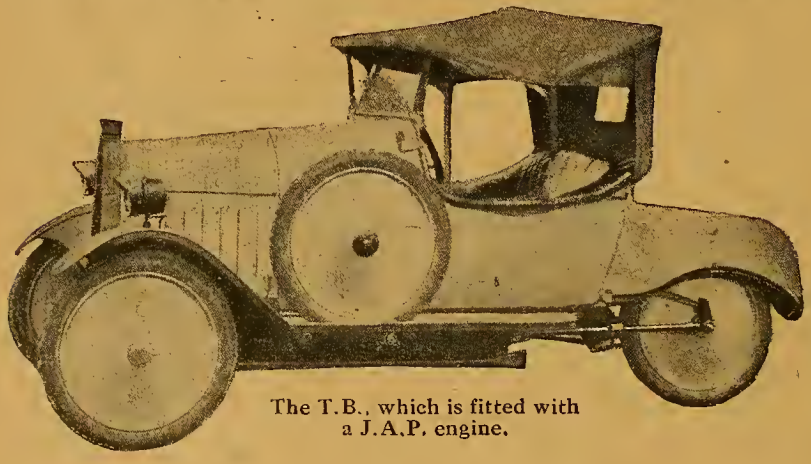
employs belts in the system of transmission, this being the Wooler-Mule. Apart from this, it has several very interesting features. The final details are being jealously guarded by the makers, The Wooler Engineering Co., Alperton, but the following particulars probably will be found to be fairly accurate :—A special Wooler engine having horizontally-opposed cylinders, the bore and stroke of which are 85 mm. and 90 mm. respectively, is placed under a bonnet at the front of the car, a cooling draught being introduced through cowling by means of a convex-shape flywheel open to the atmosphere at the front and vanes upon the periphery of this wheel which suck in and distribute air round the cylinder heads. The drive from the engine is transmitted through expanding pulleys, of which there are six, three on the extension of the crankshaft and three on the main propeller shaft immediately beneath it, which transmits the final drive to the rear wheel. This car will be shown on Stand No. 47, the price working out at £130.

The Castle Three, a newcomer to the ranks of three-wheelers, employs shaft and bevel drive, being thus a marked contrast to the Morgan, the Coventry Premier, and L.S.D., with chain drive, and the Bantam with friction drive; moreover, it is fitted with a Dorman engine, and, therefore, should be an exceedingly powerful little machine. Epicyclic-type gears are employed, the clutch being arranged within the gearbox. A decided departure from the adopted for the steering. The lighting is electric or, at a reduced price, either acetylene or oil. The car is made by the Castle Motor Co., Ltd., Kidderminster, the price with equipment and electric lighting being £250.



The chassis of the "Castle Three."

other three-wheelers seen at the Show is the method of springing adopted on the Castle Three : it is fitted with quarter-elliptics at the front, but semi-elliptic at the back—a determined attempt to eradicate one of the minor disadvantages of three-wheelers and obtain comfortable rear suspension. Planetary gear is



The T.B., which is fitted with a J.A.P. engine.

Amongst those machines which are crowded out of Olympia the M.B. and the T.B. are worthy of mention. The M.B. is a particularly striking cyclecar both as regards outward appearance and design. It is fitted with a four-cylinder water-cooled engine, Zenith carburetter, and Thomson-Bennett magneto, two forward gears and a reverse being provided. Transmission is by shaft and chain, semi-elliptic springing being fitted at the front and quarter elliptic at the rear. The equipment includes spare wheel, and the price of the car—which is made by Merrall Brown Motors, St. George's Road Works, Bolton, Lancs.—is £250.

The T.B. is fitted with a J.A.P. engine (85.5 mm. by 85 mm.), the carburetter being an A.M.A.C. and the magneto an M.L. Two speeds and reverse are provided, the drive being transmitted by shaft to the rear wheel, the final drive being by bevel. A noteworthy point of the T.B. is the method of suspension at the rear which is on the cantilever principle. Full equipment is provided, including spare wheel, the price being £200 and the manufacturers Thompson Bros. (Bilston), Ltd., Aircraft Dept., Bilston.

THE O.K.-UNION AND LEVIS END-TO-END TRIPS

ONE of the stunt rides which we mentioned in our last week's issue is that undertaken by P. Pike, who, mounted on a 2¾ h.p. O.K.-Union, set out last week to ride from John o' Groats to Land's End in five days. The test is being officially observed by the Auto-Cycle Union.

On Monday we received the following wire :—"Banff.—O.K.-Union going well on most difficult roads of snow, ice and water. Great strain on rider to prevent frequent broadside sliding. Too dangerous to proceed in dark, therefore three hours behind schedule. Resume in morning for Aberdeen and Perth. Muddy roads will be welcomed as a picnic."

The next communication reached us on Wednesday, and was dated from Edinburgh. It said :—"O.K.-Union proceeding through abnormal road and weather conditions—ice, snow, mud and deluge of rain. Making Newcastle to-night, going well; half-day behind schedule."

On Thursday we were notified from Newcastle :—"Torrents of rain at Edinburgh, followed by heavy melting snow. Regret we have not yet had fog. Proceeding Doncaster and Birmingham; half-day behind schedule. O.K.-Union O.K." Evidently the torrential rain has not damped the rider's humour.

After a terrible journey Capt. Pike arrived at Birmingham from Newcastle on Friday at 2 a.m., 12 hours behind the scheduled time. The worst part of the journey, from Inverness to beyond Banff, over 45 miles, was through solid ice with deep drifts of snow on either side.

After a rest they proceeded on their journey to Land's End, encountering a terrible blizzard over the Derbyshire moors. This, however, Pike considered a joy ride! The trial is proceeding at the time of closing for press.

The Levis Attempt.

DESPITE road and weather conditions of the utmost severity the standard Levis, which Kuhn is riding from the Midlands to John o' Groats and Land's End, is making good progress. The route has been altered, for, instead of returning from Land's End to Birmingham, Kuhn will come to London in order that the machine may be available outside Olympia for such as are interested. Up to the time of going to press Kuhn had reached Birmingham on the morning of Friday last, having experienced no trouble beyond the state of the roads, which were ice-bound or inches deep in water and mud. The plucky rider should reach London on Tuesday unless further bad weather intervenes, and we hope to give fuller particulars of the trial in our next issue.

The Editor's Correspondence.

The Editor is not responsible for, neither does he necessarily agree with, the views taken by correspondents. Both sides of any topic are given equal publicity. A pen-name or initials can be given for publication, but the writer's full name and address must always be sent. All communications should be written on one side of the paper only and be in ink. Envelopes should be marked "Correspondence."

The Division of Those Twenty Open Trial Permits!

The A.-C.U. and the "Twenty Limit."

It would appear from "Signals'" letter in your current issue that the Auto-Cycle Union is an autocratic body imposing, for reasons only known to itself, certain drastic rules and regulations, which the clubs have "put up with" so far, but which they "bitterly resent" and will no longer bear in "grudging silence." What could be further from the truth? The Auto-Cycle Union is a union of clubs, and it is the clubs' own elected representatives who are, of course, responsible for this so-called "high-handed action."

The proposal to limit the number of permits to be issued next year to 20 was made by a club representative at a well-attended meeting of the General Committee, and not one of the many club representatives present voted against it; but, on the contrary, received the suggestion with enthusiasm.

Surely the nom de plume of "Signals" cannot hide a Bolshevist; and this gentleman must agree that every sport must have its controlling body. If so, who better fitted to control than the elected representatives of the clubs?

This "immense dissatisfaction" and "bitterest resentment" must be very galling to those 20 club men who, in March last, had reason to think they enjoyed the confidence of their fellow-members! I admit the suggestion to limit the number of permits was originally my own, and it was made for what seemed to me very good reasons. But I must also admit that it did not occur to me that the main reason why a club applies for a permit is to revive its finances, and that, if prevented from so doing, it must "shut up shop." On the other hand, I submit that without trade support an open trial can hardly be a success from any point of view. This is regrettable, but must be faced.

During this season several applications for permits were made and granted, but subsequently withdrawn on the club's finding that the trade would not support them. I happened to know that if we, i.e., the clubs, had not taken action for next year, the trade would themselves drastically limit the number of competitions they would support; indeed, they may still take this course. (And those who pay the piper have some right to call the tune.) Which is the better—a policy of "laissez-faire," which will mean general confusion and discontent, or a cut-and-dried scheme which may not give us all we want, but should keep our competitions on the high level which in this country alone motor-cycling sport has reached?

I should like to join issue with "Signals" on another question he raises—that of the benefits of membership; but as it is entirely irrelevant to the question under discussion, I will spare your readers. But if any of them, including Mr. "Signals," care to argue this point at Olympia at Stand No. 2, I shall be delighted to meet them there.

T. W. LOUGHBOROUGH,
Secretary, Auto-Cycle Union.

What was "Signals" Object?

I notice with surprise a letter in last week's issue signed "Signals," and although I hold no brief for the A.-C.U., I should like to reply. I think that if I trace the course of events with regard to the allocation of the open permits, your readers will readily see that "Signals" has no cause for complaint.

At the end of October the secretary of the A.-C.U. wrote a circular letter to the 20 clubs in the home counties district, pointing out that four permits had been allotted to them, and suggesting that the secretaries of these clubs should arrange a meeting to decide which clubs, or which amalgamation of clubs, should run these events. Of the 20 clubs concerned, only two secretaries (Mr. Ellis, of the Woolwich Club, and myself) took any action in the matter, and eventually a meeting was arranged to be held at the A.-C.U. At this meeting only six clubs were represented, two wrote saying they did not intend to organize open competitions next year, two more wrote intimating their desire to amalgamate with other clubs, and one wrote more or less demanding a permit, and this one I very much suspect to be our friend "Signals," thus leaving nine clubs who apparently had no interest in the matter. Of the six secretaries present, two of these expressed the opinion that they did not desire to apply for permits.

Now, in analysing the results obtained, it was agreed that the Woolwich, Streatham, and Rochester Clubs should have the right to apply for one permit. We ourselves (the Essex M.C.C.) agreed to run our Southend speed trials in conjunction with the Southend Club, and in view of "Signals'" absence he could hardly have been surprised if the right to apply for the remaining two permits had been divided by those clubs which did attend, but the feeling of the meeting was that they did not desire to have the only places in the sun, but would rather give some of the smaller clubs a chance, and therefore the right for a permit was given to "Signals." Even then there still remained a further permit to be given, and this was left over to be allocated to one of the remaining nine clubs.

What does "Signals" hope to obtain? He has got one open permit, for he asks for in his letter; other clubs have got what they asked for, and there still remains another permit for allocation. What does he want?

Now one further point. "Signals" states that trade support is not necessary. Let him then organize a club meeting, and to attract the unattached sportsmen let him make them members of the club for the day only, at a nominal fee. He would then not require a permit. I shall anxiously watch next year's trials and see whether he takes this advice.

Now, "Signals," I would repeat that you have obtained one permit, other clubs having got what they want, and we still have one left. What is the object of your letter?

DOUGLAS S. KAPADIA,
Hon. Secretary, Essex Motor Club.

Correspondence (contd.).

A Competition Riders' Union.

I should be glad to hear from enthusiastic competition riders with a view to forming some sort of a union for the purpose of determining what clubs and trials should be supported. Under the present system the actual rider has nothing to say in the matter, and I, for one, am very fed up with the methods of some clubs in their competitions.

ALBERT MILNER, Lieut.

Dr. A. M. Low on the Paris-Nice Trial.

May I be permitted to draw the attention of both riders and manufacturers to the forthcoming Paris-Nice trial to be held in the early spring of next year. This trial is likely to be very well supported, and will lead to a great amount of publicity apart from its own value. I feel that it is most important for us to realize in this country how large are the markets covered by a Continental trial of this kind, and I have been asked by one of the principal promoters to bring it to your readers' attention.

A. M. LOW, A.C.G.I., etc.

Captured from a German officer in Palestine, this photograph of a German repair shop is the more interesting because the tyreless motorcycles bear out the rumours of the rubber shortage which existed towards the end of the war. The machines depicted are N.S.U.s.

A Motorcycle Circus Suggested.

An idea thrown out by a new comer to the world of motoring created a suggestion which I should like to pass on to you. When he heard that there was to be a Cycle Show at Olympia he said, "Oh, on the same lines as the Naval and Military Show, I suppose." It will be remembered that in the Naval and Military Exhibition each section of H.M. Forces sends a representative body to show the worth and skill of that section to the general public, and doubtless by this he meant that each firm would send one or more of their motorcycles of the type for the coming year, and twice a day for six days they would be "put through their paces" in the arena, with the tiers of seats, which hold umpteen thousand people, full of the motorcycling world.

And why should not this be so? I do not for one minute suggest that the present type of Show should be abolished. Far from it, for it is the sole joy of manufacturers, and is exceedingly good for prospective buyers desiring a close view of the machines. Hold both shows, so that the exhibitor of the first show can carry out his boasts in the second.

There are about 80 firms who would be exhibiting, and if each type of cycle was given about two minutes, and such exhibits as magnetos and tyres given a little less, the whole thing would take about three hours. Or it could be worked on the cinema system—"continuous performance" from 10 a.m. to 10 p.m., comprising four "turns" daily—and you could walk it at any time and complete the "round."

The various subjects capable of being dealt with are the main essentials of motorcycling, and include:—

1. Silence.
2. Hill-climbing—an artificial hill of gradient of 1 in 4.
3. Slow running.
4. Fast running.
5. Easy starting.
6. Accessibility.
7. Interchanging of wheels.
8. Magnetos—an artificial pond.
9. Steering—a hairpin track.

There are other things your readers may think of. Each firm could have half-a-dozen machines in the arena at once, and tyre firms could fit up their own apparatus for showing non-skid and puncture-proof devices.

CYRIL THRIPP.

The Judge's Report.

I notice that Mr. Cyril Thripp is taking myself and others to task for having criticised the Six Days' Trial before the Judges' Report was issued. There is undoubtedly a certain amount of truth in his remarks published on November 19th, but I would like to point out that it was the *Trail* which was being criticised two months ago, and not the report. It should also be remembered, as was pointed out in an Editorial footnote last week, that thanks largely to the two months' delay in the publication of the report, the Judges had had ample time in which to think out the wording in such a way as to answer many of the criticisms which they had heard from time to time.

That the Auto-Cycle Union admit many of the accusations on the Trial is borne out by the fact that in several cases they altered their regulations and system of deducting marks, after listening to the many criticisms.

As regards the publication of the petrol consumption test, I was rather surprised to see this done, having inside information as to the manner in which the consumption was measured. As a good deal of mystification exists on this matter, I see no harm in stating now that the level in competitors' petrol tanks was measured on several occasions before the morning's start, unknown to the riders. At the lunch stop the Judges noticed how much spirit had to be poured into the competitors' tanks until it reached the same level. There is absolutely no guarantee that additional petrol was not added by the competitors during the morning's run, which I am afraid rather detracts from the value of the published figures.

I still maintain that the brake test was a farce; the Judges admit that they only took into consideration brakes which were out of adjustment or ineffective at the end of the Trial, there being no actual road test. The only road test which will ever do away with ineffective front brakes is the descent of a steep hill in neutral, only one brake at a time being used.

TOURIST.

SPECIFICATIONS AND PRICES AT A GLANCE.

Below, and on the following pages, appear details of the principal motorcycles now being manufactured. Prices are given where these have been decided at the time of going to press, but we are asked to state that they are liable to fluctuation. In many cases models slightly different from those described can be obtained, as detailed in the footnotes. The list does not pretend to be a complete one of all motorcycles made. Many little known machines of similar construction, built up from components, are omitted.

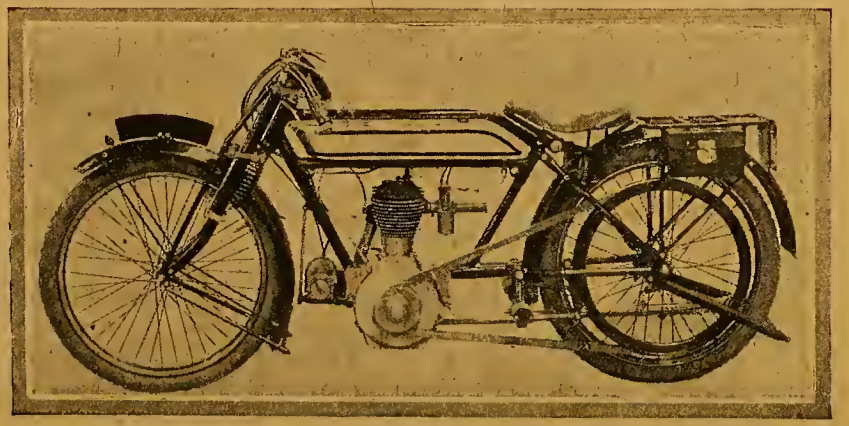
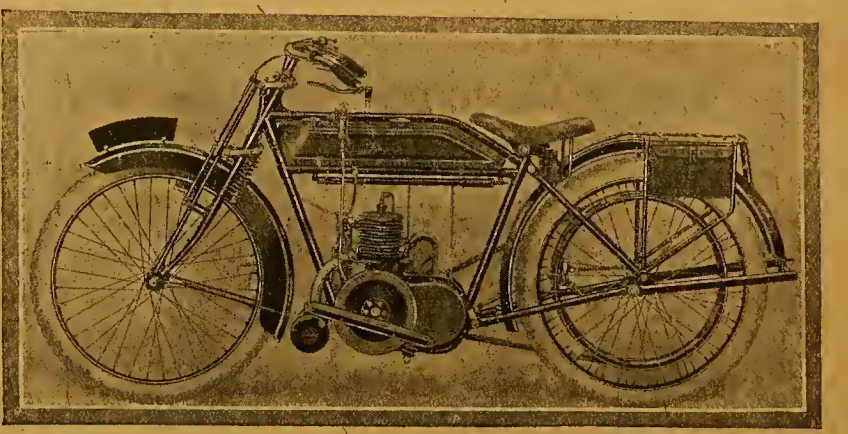
A. Single speed or clutch optional.
B. 26 by 2¼ tyres to order.
C. Also clutch model.
D. Also single-speed model.
E. Also Isle of Man sporting models.
F. Ladies' model also made.
G. Enfield two-speed gear optional.
H. Sidecar combination.
I. 8 h.p. engine same price
J. Electrical equipment to order.
K. Electrical equipment and interchangeable wheels.



One of the few T.T. machines still to be made—the Norton—guaranteed to do a certain speed.



The "Baby" James is a two-stroke machine of sturdy appearance and is exceptionally well finished.

The OLYMPIA SHOW

COMPLETE REVIEW OF MOTOR CYCLE EXHIBITS.

In the following pages will be found a complete review of the motorcycles exhibited at Olympia, arranged in alphabetical order. Scooters, lightweight sets, sidecars and accessories are dealt with in separate sections.

Stand No. 23.
Sopwith Aviation Eng. Co., 65, South Molton Street, London, W. 1.

THE exhibit on this stand is the much-talked-of A.B.C. motorcycle, designed and constructed on aero practice lines. The engine is of the horizontally-opposed twin type, set across the frame, and having cylinders of 69 mm. bore and 54 mm. stroke. It is rated at 3 h.p.

A solid two-throw crankshaft is employed, with roller bearings to the connecting rod big ends. The pistons are of aluminium alloy, and fitted with three extremely narrow rings. Detachable heads are provided to the cylinders, the barrels of which are turned from the steel bar and afterwards heat treated to ensure good wearing qualities.

The magneto is situated on a platform immediately above the cylinders, and just aft of it is the automatic single-lever carburetter, which supplies gas to the engine through an exhaust-heated induction pipe.

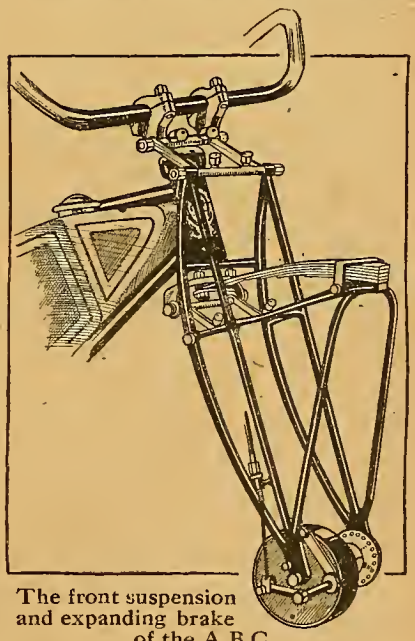
The drive to the gearbox is by a short shaft and bevels, and four speeds are provided, operated by a long lever, working in a gate, mounted on the unit casing. Final transmission to the back wheel is by roller chain, with shock absorber in the rear sprocket.

The frame is sprung on laminated leaf springs, rigidly secured at each end, and so obviating the use of shackles and pins. The top rail slopes from head to saddle, the other tubes forming a cradle in which the engine rests, and of sufficient width to protect the cylinders in case of a fall. By merely undoing four bolts the entire engine and gearbox unit may be dropped out of the frame.

The brakes act one on each wheel, and both are of the internal-expanding pattern. An electric lighting set can be fitted to order, in which case the Lucas dynamo is housed in a portion of the unit casing and the accumulator slung in a metal box on the seat tube. The finish of the complete machine is in dull black, resembling gunmetal.

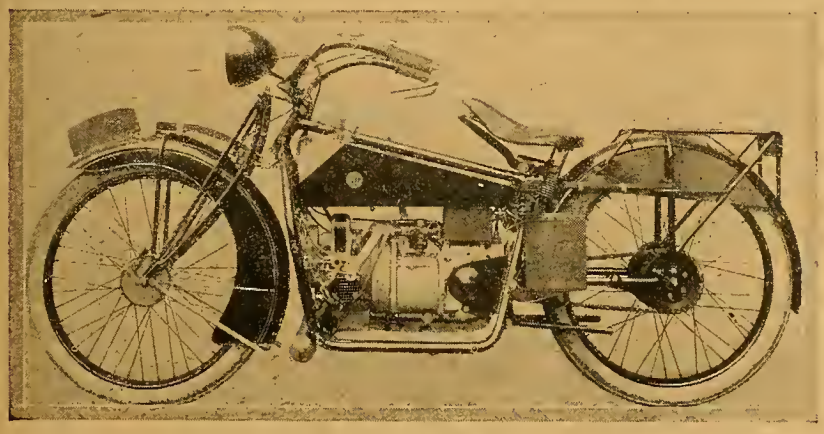
Stand No. 31.
Stevens, A. J., and Co. (1914), Ltd., Graiseley House, Penn Road, Wolverhampton.

VISITORS to this stand will miss the little 2¾ h.p. model of pre-war Shows, and the decision of the concern to suspend manufacture of this efficient and popular little mount will be received with regret. However, A.J.S.s have a fine display. The 6 h.p. twin three-speeder may be had either solo or with their very handsome sidecar, replete with spare wheel and other luxuries too numerous to mention. Practically no alteration is made upon 1919 practice, save that the footboards have been supplied with rubber half an inch thick and parallel valve springs have been substituted for the conical variety. The engine has side-by-side valve and detachable cylinder heads, which are not fitted, however, for decarbonization purposes. The makers recommend that carbon be removed by detaching the whole cylinder in the ordinary way.



The front suspension and expanding brake of the A.B.C.

The carburetter is an A.M.A.C. multiple-jet two-lever instrument, and the magneto is a Thomson-Bennett model, chain driven and controlled from the handlebar. The three-speed gearbox is on well-tried car lines. High and low gears are held by dogs, while the middle ratio is engaged by a sliding pinion. Ball bearings are used throughout. The ratios are 4.92, 8.86 and 15.92 to 1. This low ratio should enable the outfit to climb any hill in the country. Gear changes are effected by a patent gate change-speed lever having an automatic stop for each gear.

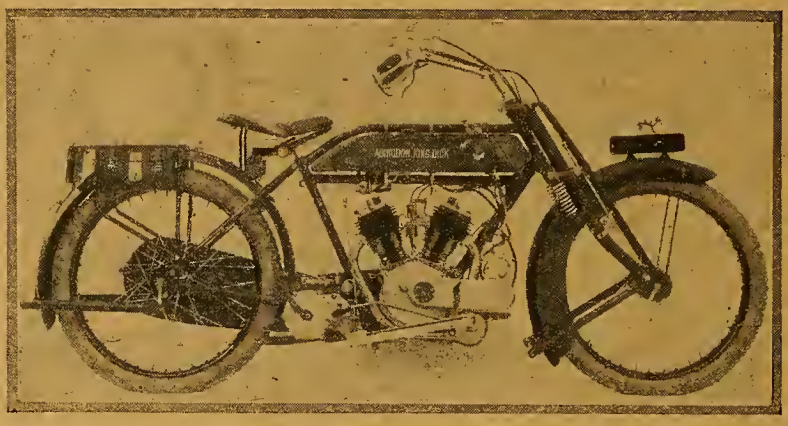


The 3 h.p. A.B.C. has so many original features that it is one of the centres of attraction at Olympia.

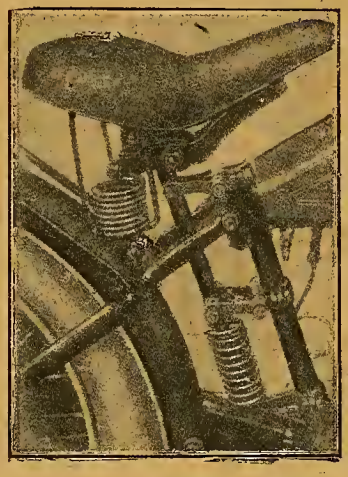
A.J.S.—Abingdon King Dick.

The frame is built up without a single bent tube in its design. The tank fits over the slanting top tube and thus presents a clean top, except for the oiler pump and filler caps. Its capacity is 2½ gallons of petrol and three pints of oil. A Best and Lloyd semi-automatic oiler in a vertical position on the tank top supplies the engine.

The chains are Hans Renold, ⅝ in. by ⅜ in., enclosed in perfectly weatherproof cases. They may be inspected without the use of tools, and, further, the back wheel, clutch, sprockets, chain, and kick-starter (this latter also enclosed) may be removed without disturbance to the chain cases. The wheels are all detachable and interchangeable, the spare being carried at the back of the sidecar above the luggage grid. It is held in place by two very neat clamps to the rim with thumb bolts. The front brake is a Bowden of conventional design, but the back one is



The 6-7 h.p. Abingdon King Dick is supplied with either all-chain or chain-cum-belt transmission.



A spring seat pillar ensures easy riding on the A.J.S.

of the internal-expanding type with large shoes on car lines, operated by the foot on the left of the machine.

The stand is worthy of special mention on account of its ease of operation. On the right-hand side is a lever, folding back and running the whole length of the stand "leg." When opened out, this lever renders the jacking of the back wheel a simple matter even for ladies. Tyres are heavy Dunlops, 700 mm. by 80 mm., with mudguards of ample size.

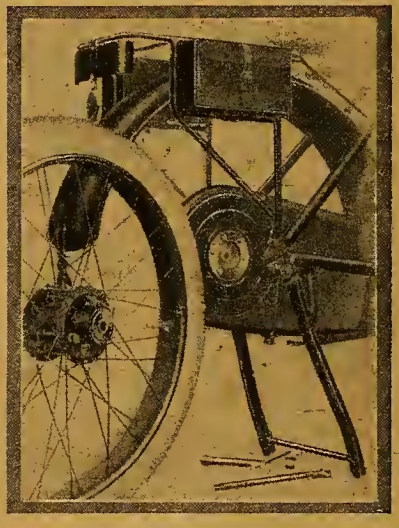
The entire outfit, including handlebars, is finished black of a surprising gloss; this to obviate frequent plating. A few special parts have been found more serviceable when plated, and here the plating is heavy.

Stand Nos. 34 and 140.

Abingdon-Ecco, Ltd., Tyseley, Birmingham.

A 6-7 h.p. twin-passenger combination and a 3½ h.p. single-cylinder machine form the exhibits of this company. The sidecar model is equipped with an Abingdon King Dick V-twin engine of 73 mm. by 95 mm. bore and stroke respectively. A feature of this engine is the unusually large ports; the lubrication is effected by suction from a separate oil compartment in the main tank.

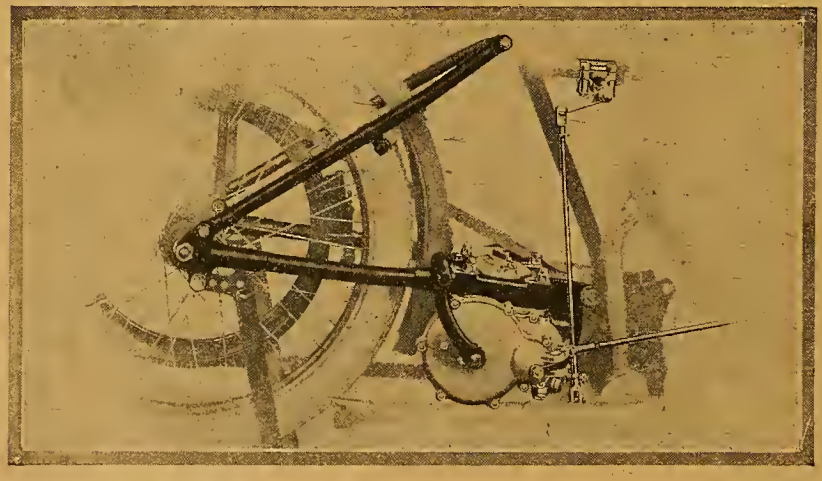
The specification includes three-speed gear and clutch of the countershaft bottom bracket type, and the transmission is either by chain and belt or all chain with shock absorber, as desired. A 6-in. ground clearance is allowed. One of the principal new features is the detachable hubs; the wheels are interchangeable, and by the use of a neat and efficient arrangement the back wheel can be removed from the frame without upsetting the chain adjustment. The back



All wheels on the A.J.S. combination are quickly detachable and interchangeable.

mudguard is hinged, and can be swung back to allow of the easy removal of the wheel. Stands are fitted to both front and back wheels, and the machine is exceptionally well equipped and finished. The 6-7 h.p. machine is suitable for either solo or sidecar work.

The 3½ h.p. models retain their former specification, and are made in two patterns, one with a three-speed countershaft gear and the other as a belt-driven T.T. machine.



Abingdon King Dick machines have sturdy countershaft three-speed gearboxes.

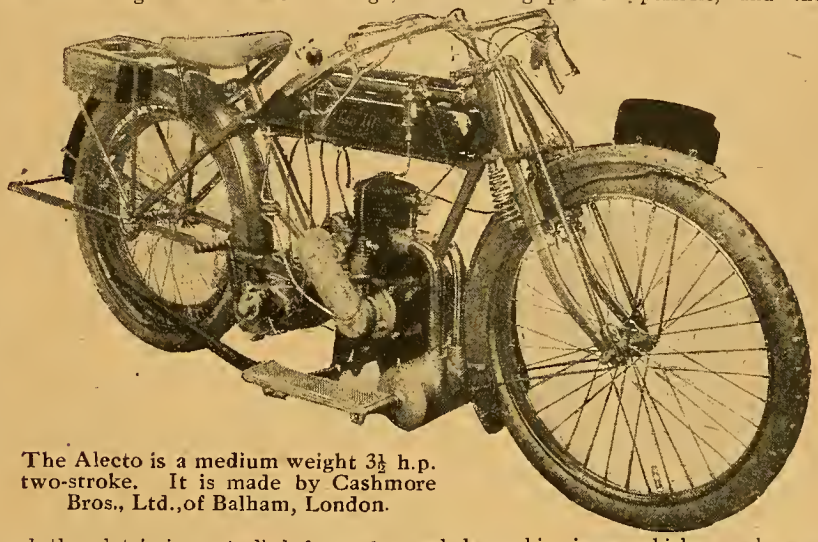
The Alecto Two-stroke—Allon Lightweights—Ariel Models.

Stand No. 15.
Cashmore Bros., Ltd., Hildreth Street, Balham, London, S.W. 12.

CASHMORE BROS. are showing two standard Alecto machines which are fitted with 3½ h.p. two-stroke engines and the Jukes' two-speed gearbox, which incorporates a clutch and kick-starter. The machines are chain and belt-driven, and are made throughout from the finest material. The engine employed has a bore and stroke of 76 mm. by 76 mm., and is of the three-port type. The piston, which is of the usual deflector pattern is made from aluminium alloy, and is fitted with three rings which are pegged in position, the lower ring acting as a scraper. A double row of Skefko ball bearings support the crankshaft, while the big-end is lined with white metal. The method of lubrication is as follows:—Oil is fed in at the inlet port and runs down to a well formed in the top of the crankcase. From here it passes through two holes drilled in webs on opposite sides of the crankcase to each main bearing. The main shaft and crank web are drilled in the transmission side, and oil is conducted through this passage to the big-end. The machine is unusually well equipped, and the specification includes Brampton Biflex forks, Brooks B150 padded saddle, Dunlop heavy 26 by 2¼ tyres, and Dunlop belt. The present price of this machine is £83 7s.

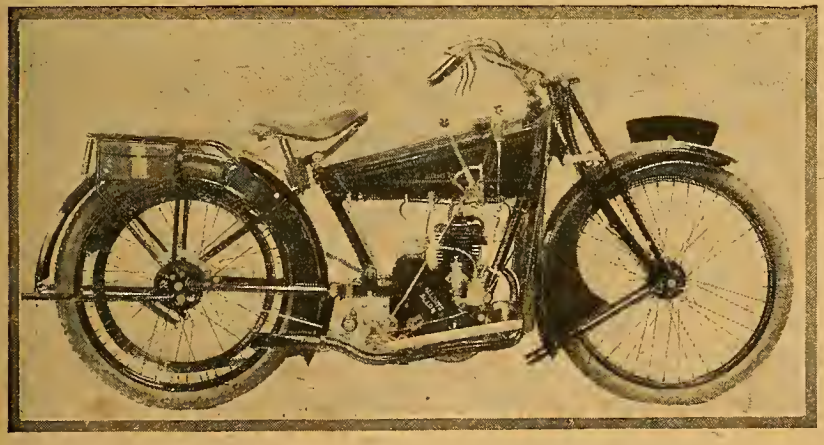
ing with any other portions of the machine This makes decarbonization a particularly simple operation.

The magneto is carried behind the cylinder, high up out of the way of water, and protected from rain by the tank. The gearbox is neat in design, and the clutch is controlled from the handlebar. Chain-cum-belt drive is employed, and the belt is adequately protected. The chain is neatly encased, and



The Alecto is a medium weight 3½ h.p. two-stroke. It is made by Cashmore Bros., Ltd., of Balham, London.

The large mudguards and footboards make a machine which is very clean to ride in all weathers, and when these are augmented by leg shields nothing further in the way of weather protection is needed. The frame design makes a very low riding position possible, and the whole machine is one which appeals particularly to business men, who must have considerable regard for appearances.



The Allon lightweight is a popular little mount of smart appearance.

Stand No. 104.
Alldays and Onions, Matchless Works, Birmingham.

TWO examples of the Allon two-stroke are shown, and they undoubtedly belong to the lightweight de luxe class, with their large tanks, two-speed gears, kick-starters and clutches. The engine is of the three-port type with outside flywheel, and is interesting from the accessibility of the various parts. The lower portion of the crankcase may be removed by undoing eight bolts, and the crankshaft and flywheel, together with the connecting rod and piston, may then be removed as a whole, without interfer-

attention to detail has been carefully studied all through the complete design. A case in point is the guard which protects the brake. Both front and rear brakes are by contracting spring bands on drums attached to the hubs.

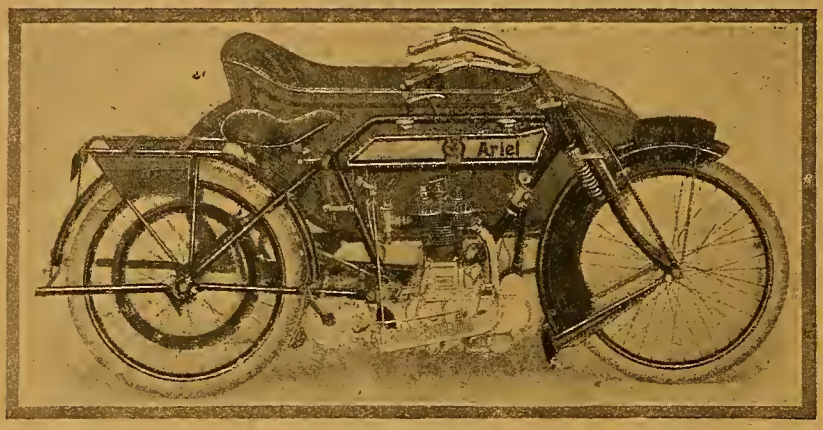
The strong frame of the Allon will be noticed; no bent tubes are employed at all. The sloping top tube was early adopted by the Allon, and the tank design is particularly pleasing. The tank is of the saddle pattern and encloses the top tube, giving a very neat appearance, besides great strength. This does away with one dust trap, the crevices formed by the exposed top tube and the tank.

Stand No. 59.
Ariel Works, Ltd., Bournbrook, Birmingham.

THE Ariel programme for 1920 comprises four models, two of which are entirely new. The present models, 3½ h.p. single-cylinder and 6-7 h.p. twin, are retained, with a number of improvements, such as larger and wider mudguards and new pattern wheel hubs. Both these models have the Ariel three-speed countershaft gearbox and chain-cum-belt transmission.

The new models are a 4½ h.p. single-cylinder and a 6-7 h.p. twin-cylinder, both with all-chain drive. The 4½ h.p. machine has an engine with bore and stroke of 86.4 mm. by 100 mm., giving a cubic capacity of 586 c.c. The valves are very large and wide apart, and the valve pockets have large air spaces completely surrounding them. Lubrication is by means of suction from a pump, with an improved system of oilways to all the wearing parts, and the well-known Ariel decompressor is fitted to ensure easy starting. Transmission is by chain throughout, and a shock absorber is fitted in the back wheel. The frame has been specially designed to give a long wheelbase, long head, and duplex front tubes. The saddle is mounted on the Ariel spring seat pillar, and the position is low, whilst yet allowing a 6-in. ground clearance, a fact that will be much appreciated by Colonial riders. The wheels are fitted with 28 in. by 3 in. Dunlop tyres, and the mudguards are extra wide, with side valances to both wheels. The back brake is of the internal-expanding, and the front brake of the ordinary rim type.

The B.S.A. Twin and Singles—The Bat Range.



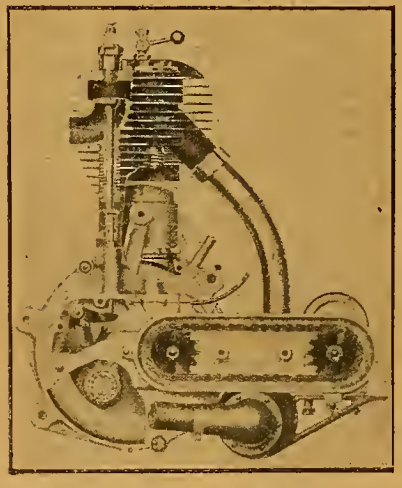
The 4¼ h.p. Ariel single-cylinder is a new model eminently suitable for sidecar work.

An interesting feature is the tank, which, although very large, is not unsightly. The petrol capacity is 2½ gallons, and the oil capacity 5 pints. With these filled up it should be possible to travel 150-200 miles without replenishing, an item that is particularly useful to riders who use their machines for night work.

The twin-cylinder model combines the above-mentioned improvements, with the exception that it is fitted with the Ariel 6-7 h.p. engine.

Stand Nos. 188-75.
Birmingham Small Arms Co., Ltd., Armoury Works, Small Heath, Birmingham.

MODELS of the well-known B.S.A. motorcycle are shown at Olympia with 3½ h.p. and 4¼ h.p. single-cylinder, and the 6-7 h.p. twin-cylinder engines.



A sectionized B.S.A. single-cylinder engine.

The former two are shown in various types, the all-chain drive Model H, which lists at £95, the chain-cum-belt model K at £93, and the 3½ h.p. T.T. model D at £77, single gear. The B.S.A. coach-built sidecar, model 2, is also shown.

These models are similar in the main to those of the 1919 season; a newcomer, however, is the 6-7 h.p. machine, which was described recently in *Motor Cycling*. This has a twin-cylinder engine of 76 mm. by 85 mm. bore and stroke, giving a cubic capacity of 771 c.c. The cylinders are placed at an angle of 50 degrees, the valve ports are of ample proportions, and all corners and recesses in the cylinders have been avoided. A cush drive is attached to the engine shaft, six powerful springs absorbing all engine shocks and ensuring flexible transmission. Mechanical pump lubrication is employed, together with an auxiliary hand pump.

Transmission is effected by means of ⅝ in. by ⅜ in. roller chain, with the B.S.A. three-speed countershaft gearbox. The clutch is situated in the large chain wheel, and is of the dry-plate variety, controlled from the handlebar. The rear brake is internal-expanding, whilst the front brake operates on a belt rim fitted for the purpose. The mudguards are 8¼ ins. wide, and the wheels are 28 in. by 3 in., tyres being Dunlop extra heavy or Palmer cord light car type.

Finish is in the usual B.S.A. black and colouring, mudguards and gearcases being lined in gold, with the usual bright parts plated. The price is £130 solo, or £168 for the combination. The spare wheel is £9 9s., and the electric lighting set £29 extra.

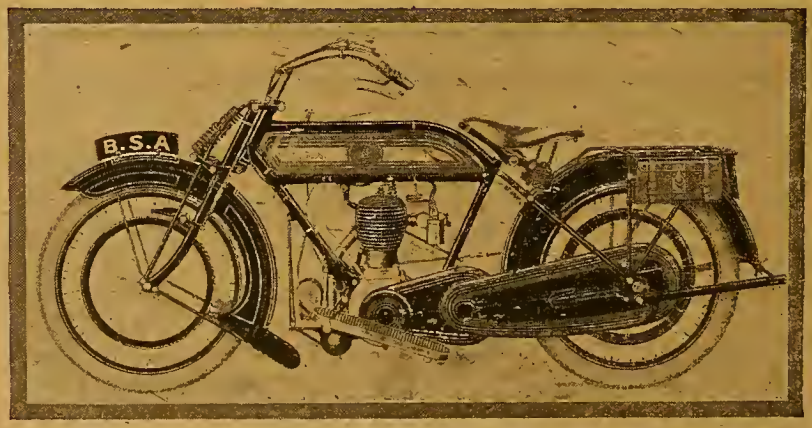
A spring seat pillar ensures easy riding on the B.S.A. twin.

Stand No. 82.
"Bat" Motor M'fg. Co. (1918), Ltd., 2, Kingswood Road, Penge, S.E. 20.

THE various models on view on this stand indicate that those responsible for the design of the Bat motorcycle are by no means content to rest on their laurels. It is interesting to note that the original Bat machine made about 1902 included independent springing of the driver as part of the design, and this feature is still retained on the present-day models, in a much improved form, of course.

A choice of either a 6 h.p. or 8 h.p. J.A.P. engine is offered at the same price. The drive is by chain throughout through a well-designed three-speed countershaft gearbox, top and low gear wheels being constantly in mesh, the second speed being engaged by a sliding pinion. The clutch is of unusual design, being an internal-expanding phosphor-bronze ring operated by means of wedge bars.

The new detachable wheel, particulars of which were given in a recent



The 4¼ h.p. B.S.A. is a sturdy solo or sidecar mount.

The Bradbury Range—The Interesting Design of the Black Prince.

issue, is worthy of notice, inasmuch as the design allows easy removal without the use of loose distance pieces. This operation can be performed in a surprisingly short space of time, the chain and bearing adjustments remaining unaffected. The chain wheel runs on its own adjustable bearings, and has dogs formed on its inner face, through which the drive is transmitted.

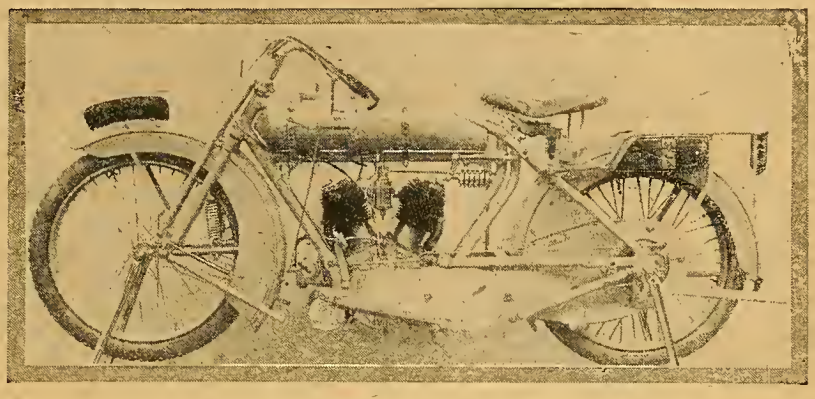
We have already referred to the Bat system of carrying the saddle and footboards on a separate sprung member. Both brakes operate on the rear wheel, these being of the internal expanding and external contracting band type. The sidecar is most roomy and comfortable, the spring wheel, in conjunction with the body springs, providing luxurious suspension. Five-point attachment is employed.

Resplendent in grey enamel, the Bat machines present a very serviceable appearance, and the fact that the designer is himself a practical motorcyclist is a point which will carry weight with prospective buyers. The price of the three-speed detachable wheel combination, 6 h.p. or 8 h.p., is £164, electrically equipped, £181, which figures include a spare wheel.

Stand No. 52.
Bradbury and Co., Ltd., Wellington Works, Oldham.

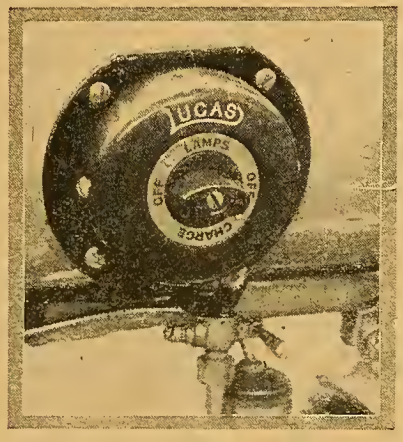
THREE models are shown:—The new 2¾ h.p. four-stroke lightweight, the 4 h.p. single-cylinder medium weight, and the 6 h.p. V-twin passenger machine.

The lightweight has a single-cylinder engine of 74.5 mm. bore and 80 mm. stroke, giving a capacity of 349 c.c. A detachable head is fitted, held by two long bolts and a bridging piece. Adjustable tappets are provided, and the timing gear has only one cam wheel. Chain-cum-belt transmission is employed, in conjunction with a two-speed countershaft gearbox with hand-controlled clutch and kick-starter. The frame is of neat appearance, with the duplex front down tubes which are a feature of all Bradbury models. The Druid spring fork has a front rim brake, and the rear wheel a foot brake working in the belt rim.



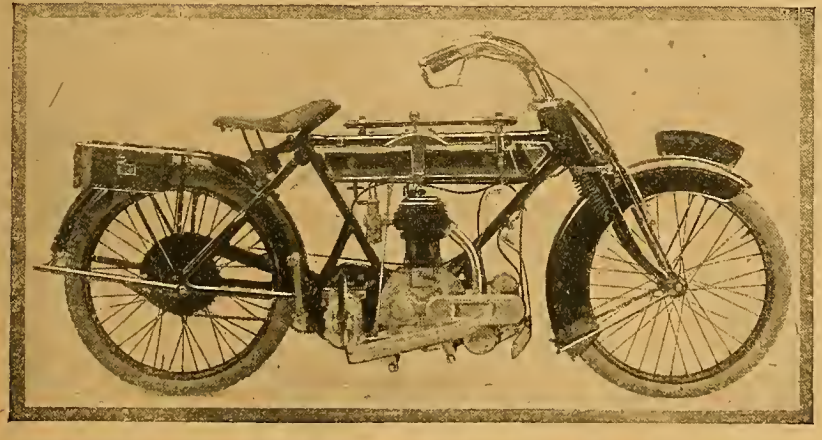
The new spring frame B.A.T., a most attractive machine.

The 4 h.p. machine is of 89 mm. bore and stroke (554 c.c.). It now has all-chain drive and three-speed countershaft gearbox with hand-controlled clutch. Except for this and the fact that the tank is finished black with gold lining, the machine remains the same as in 1914.



The tank switch of the B.A.T. lighting system.

The 6 h.p. model has a V-twin engine of 74.5 mm. by 86 mm. bore and stroke (750 c.c.). Detachable heads are fitted in the same manner as on the lightweight. The gearbox provides three speeds, with kick-starter and hand-and-foot-operated clutch, the latter being a valuable feature on any sidecar machine. All-chain transmission is employed, with semi-enclosed rear chain. The rear wheel is quickly detachable, having a knock-out spindle. The footbrake is of the internal-expanding type, working inside the rear chain sprocket, and the front brake is of the rim pattern, hand operated.



Bradbury's now make three models; the 4 h.p. single is here illustrated, and has now all-chain drive.

Stand No. 42.
Black Prince Motors, Ltd., Thorngate Mills, Barnard Castle.

MUCH interest will no doubt centre round this stand, for two reasons. Firstly, the machines are of a most unconventional design, and, secondly, the selling prices are extremely moderate.

The 3½ h.p. engine is a horizontally-opposed two-stroke, employing only one sparking plug, and a common combustion space. The mechanical balance is the same as in the ordinary four-stroke h.o. twin, i.e., both pistons travel outwards and inwards together. On their outward stroke they draw a charge of gas into the crankcase from the carburetter, and on the inward stroke expel it into the common combustion space via an automatic valve directly opposite the plug. Thus the force of the explosion acts equally on both pistons, forcing them inwards and sending a fresh charge through the transfer passage.

The engine is placed lengthways in a pressed-steel frame, and carried on a sub-frame of steel strips. Side panels are used completely to encase the mechanism. The rear wheel is sprung by volute springs placed at the lower end of the carrier supports, and is driven from the two-speed gearbox by a cardan shaft and bevels. Transmission from engine to gearbox is by chain. The gear ratios provided are 5 and 10 to 1, and the hand-controlled clutch is of the Ferodo pattern.

The tank holds 2¼ gallons of petrol and ⅜ gallon of oil, and the machine does 70-80 m.p.g. Its weight is 200 lb., and the provisional price is 60 guineas.

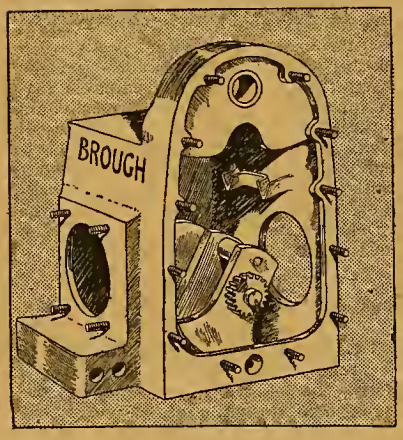
Another model to be seen on this stand is the 2¾ h.p. lightweight, fitted with Union two-stroke engine. This type weighs 170 lb., and will do 100 m.p.g. Its provisional price is 50 guineas.

The 5 h.p. Horizontal Twin Brough—Two Calthorpe Models.

Stand No. 69.

Brough, W. E., and Co., Basford, Nottingham.

ONLY one type—the 5 h.p. passenger machine—is shown, although a 3½ h.p. solo mount is also to be manufactured next year. To deal first with the model exhibited, this has a horizontally-opposed twin engine of 70 mm. bore by 90 mm. stroke, giving a capacity of 690 c.c. The crankcase is a one-piece casting, which ensures a remarkably oil-tight engine, and the solid two-throw crankshaft runs on phosphor-bronze bushes. Plain big-end bearings are employed, and are ingeniously lubricated by means of a small trough cast inside the crankcase, from the spouts of which oil trickles on to the big-ends immediately beneath. The trough is kept supplied

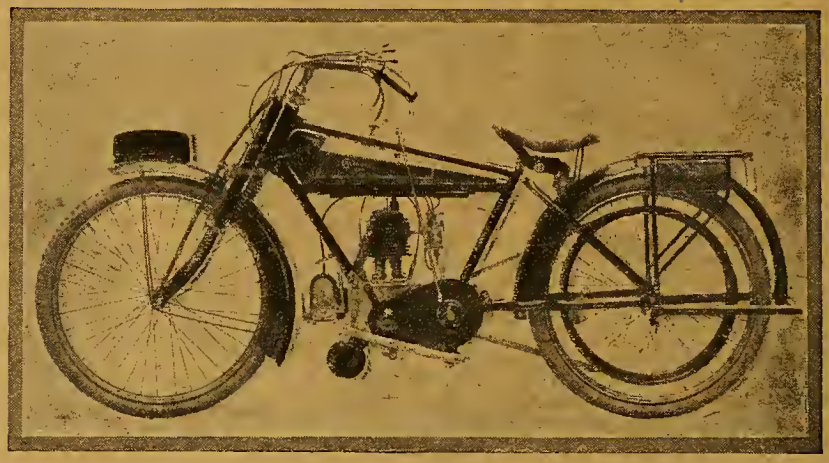


The ingenious method of lubricating the big-ends on the 5 h.p. Brough.

from a hand pump on the tank, and excess oil from the crankcase is blown on to the front driving chain so that this important part is kept continually lubricated. An A.M.A.C. carburetter is fitted, and part of the induction pipe is cast with the timing cover, in order to entail a minimum of exposed pipe.

A Sturmey-Archer three-speed gearbox is fitted at the countershaft, with the usual handlebar-controlled clutch, and all-chain drive is employed. The frame is of neat design, and low, with large and efficient mudguards.

The 3½ h.p. machine has a horizontally-opposed engine of 70 mm. by 64.5 mm., and a capacity of 489 c.c. Roller bearing big-ends are used in this engine, the inner race being a groove cut in the throws of the crankshaft, and the connecting rod forming the outer race. Aero engine practice is seen in the overhead valves and aluminium pistons. The cylinder heads are detachable, and secured by three studs.



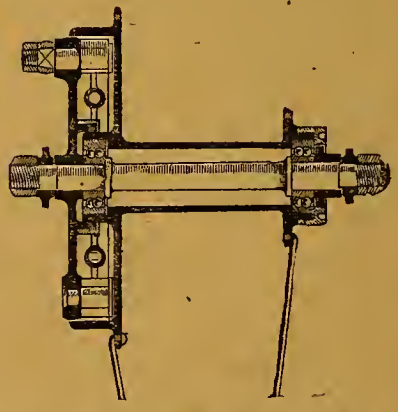
The 2¾ h.p. Calthorpe with four-stroke J.A.P. engine.

Stand No. 84.

Minstrel and Rea Cycle Co., Ltd., Barn Street, Birmingham.

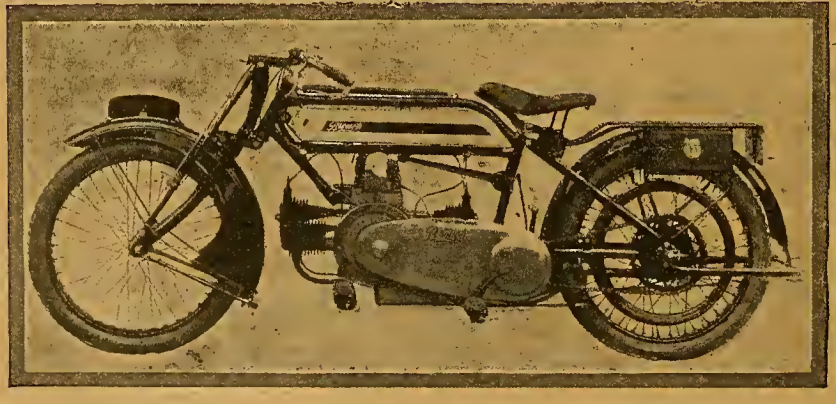
FOR 1920 there are two models of the Calthorpe, and three of each model are seen on this stand. The machines are very similar, apart from the engines, one model being fitted with the new J.A.P. 2¾ h.p. lightweight engine and the other model having the Peco engine, made by the manufacturers themselves. This is a two-stroke engine of 349 c.c., bore and stroke 75 mm. by 79 mm. The lubrication system is very thorough, as an oil duct is formed round the base of the cylinder, from which holes lead at intervals into the cylinder bore, and oil-ways from a well in the crankcase top lead direct to the main bearings.

The frame on both models has the sloping top tube now so popular, and the front forks are arranged to give a good steering rake. Druid spring forks are fitted as standard, and the 26 in. wheels are shod with 2¼ in. Dunlop tyres. An



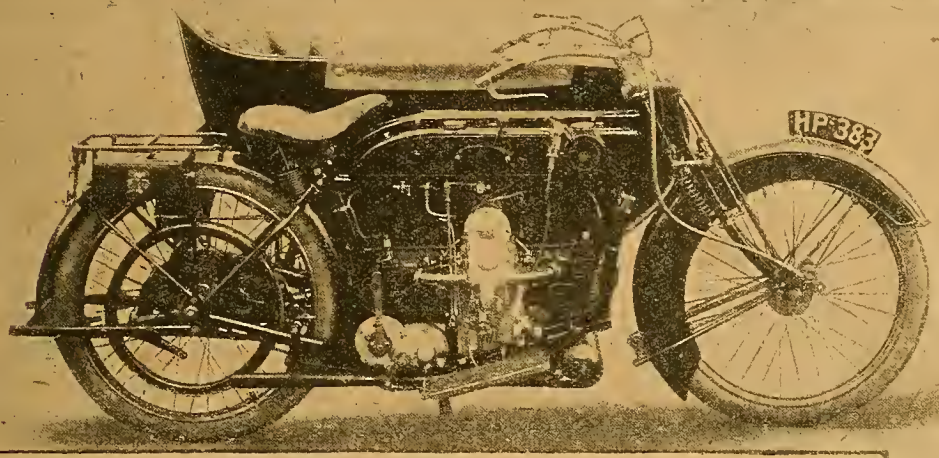
The 3½ h.p. Brough has an internal-expanding rear brake.

Enfield two-speed countershaft gear is fitted, and the transmission is by belt and chain. Large mudguards are used with side valances of ample size. Aluminium footboards are fitted, and the brake pedal is carried on the off side. On the two-stroke model the magneto is carried to the rear of the engine, but on the J.A.P.-engined machine it is carried in the forward position. A neat cast aluminium chain guard is fitted over the magneto drive, and the main driving chains to the Enfield gear are also enclosed by a metal case. A neat tubular carrier carries two pannier toolbags, and the back wheel stand is securely fastened by a strong spring clip. The whole machine forms a sturdy touring lightweight.

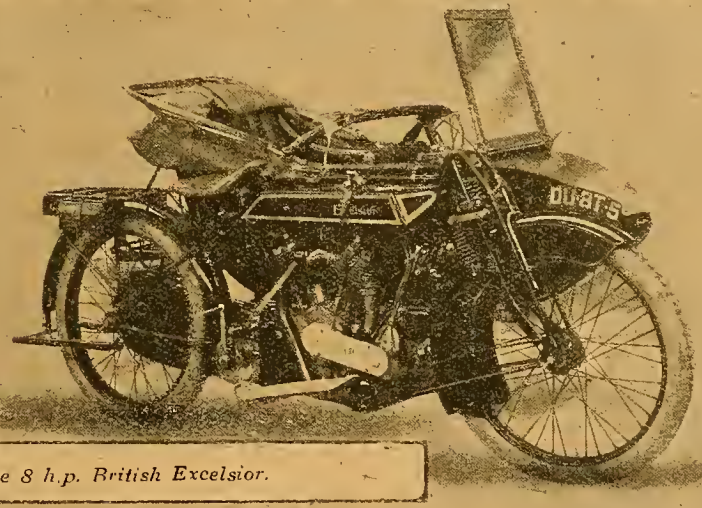


Transmission side of the 5 h.p. Brough.

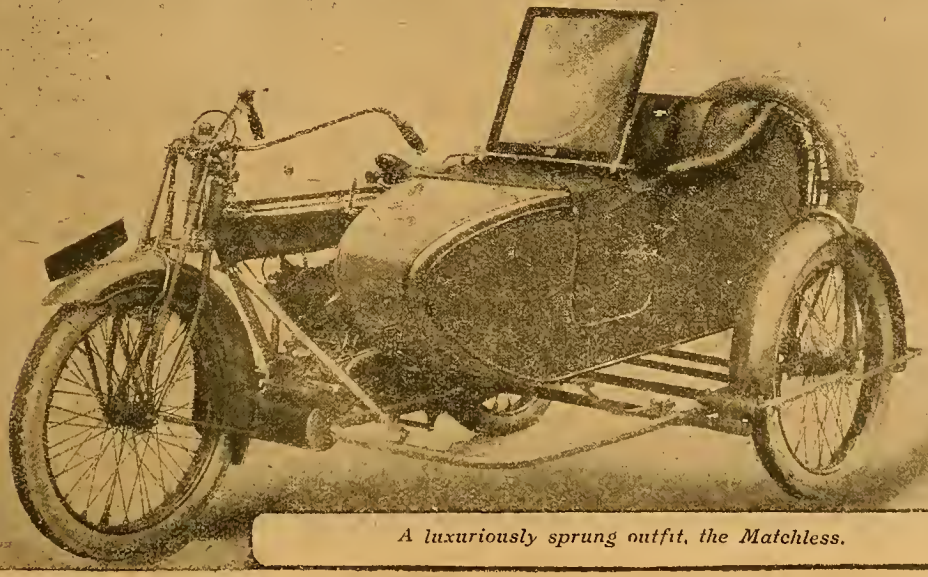
TWIN SIDECAR COMBINATIONS.



The new 4½ h.p. Humber combination.



The 8 h.p. British Excelsior.



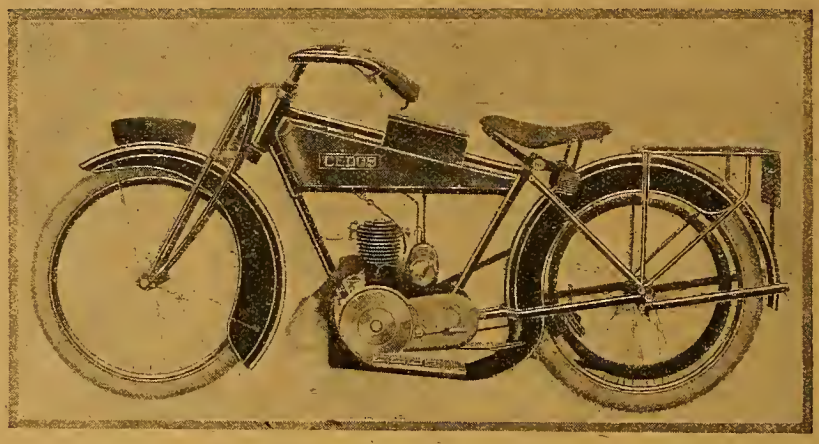
A luxuriously sprung outfit, the Matchless.

Cedos Features—The Chater-Lea Range.

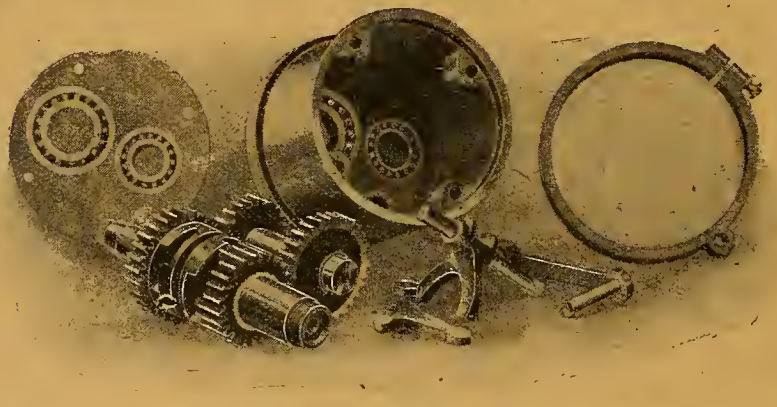
Stand No. 18.
Hanwell and Sons, Components, Ltd., Northampton.

HERE we have some Cedos lightweights which have many novel features, one of the most noteworthy being the housing of the circular gearbox in a special lug in the frame built to accommodate it. The gearbox itself is an aluminium casting, and has four pinions constantly in mesh, high and low gears being selected by movable dogs. Ball bearings are used throughout, and the gear teeth are carefully shaped. The end plate may be removed and contents inspected while the gear is in position in the frame.

The engine has a bore of 62 mm. and stroke of 70 mm. (211 c.c.). The main shaft runs on double-row self-aligning ball bearings and long phosphor-bronze bushes in order to retain compression. It will be readily understood that, as these bushes do not actually support the shaft, they should last indefinitely. Roller bearings have been chosen for the connecting rod big-end, and are Hoffmann of ¼ in. diameter. The piston and cylinders are carefully machined, to lessen the formation of carbon deposit.



Many good points are found on the Cedos two-stroke lightweight.



The Cedos two-speed gear is built into the frame.

The company's own carburetter is used; this has a variable choke tube designed specially to meet the engine's requirements. The exhaust discharges first into a bulb of 2¼ ins. diameter, whence it travels along a short pipe into a large silencer having a broad, flat pipe 2½ ins. wide and ½ in. deep. This device deadens the explosions very effectively, yet is absolutely free from back pressure, which is the maximum obtainable from any silencer. Transmission is chain to the countershaft, thence by ¾ in. rubber belt over pulleys of 6 ins. and 18 ins. diameter respectively.

The wheels are 24 by 2¼ built up on dust and weatherproof hubs. The brakes operate on the internal and external diameters of the belt rim, actuated by independent pedals.

Mudguarding has received very serious attention, the forward guard being of extra wide section and having a valance of good depth, while the rear, continuous with the undershield and long aluminium footboards, should shield the rider from anything the back wheel or transmission might throw forward in the worst weather. A ladies' model is also made.

Stand No. 83.
Chater-Lea, Ltd., 74-84, Banner Street, London, E.C.

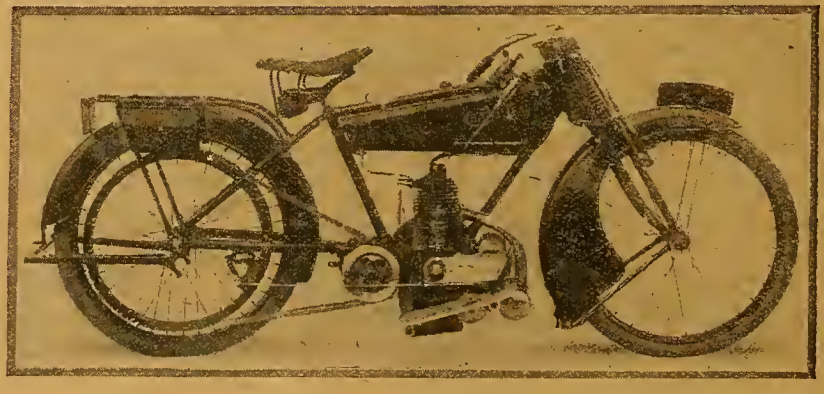
TWO 2½ h.p. lightweights and an 8 h.p. sidecar combination are the principal items of interest here.

Both lightweights are fitted with a 2½ h.p. Villiers engine and two-speed gear. Their specification includes a quickly detachable rear wheel, large section mudguards, and a novel form of front springing. The fork links are rigidly attached to the spindles, thus preventing wear at the links. The spindles have grooved oil ways cut in them, while a small oil sump is provided in the centre. A rubber buffer, entirely enclosed, which is situated at the top of the fork, permits of a slight caster movement, which has been found to be amply sufficient.

The sidecar combination is the No. 7 model, which was first introduced in 1910. It incorporates an 8 h.p. 50 degrees V-twin air-cooled engine of 85.5 mm. by 85 mm. dimensions (964 c.c.). Adjustable tappets are fitted, and the valve lifter is enclosed.

A three-speed car-type gearbox is standard, giving ratios of 3⅞ to 1, 5¾ to 1, and 10½ to 1. The clutch is of the engine shaft, multiple-disc, metal-to-metal variety, which gives a total contact surface of 130 sq. inches. The transmission is effected entirely by ¾ in. pitch chains, and 700 mm. by 80 mm. light car tyres are fitted. The back brake is of the internal-expanding type, the drum being 7 ins. in diameter by 1⅛ in. wide, and Ferodo lined.

The special Chater-Lea spring fork is fitted, and a very efficient spring seat pillar, which allows of no side movement. The lightweight motorcycle gearbox and the special front forks, in addition to a large variety of hubs, are also shown as components.



The 2½ h.p. Chater-Lea lightweight, fitted with two-stroke Villiers engine.

The Clyno Combination and Lightweight.—Connaught Models.

Stand No. 103.
Clyno Engineering Co., Pelham Street, Wolverhampton.

THREE De Luxe sidecar combinations and two samples of the lightweight machine are exhibited. The lightweight this year has a much heavier flywheel than its predecessor. The frame has been stiffened, and is now devoid of the slightest suspicion of "whip," and the handlebars are wider. Brampton forks have been substituted for the make previously fitted. Details too trivial to record have also received attention at the designer's hands. The chief feature of the model is the embodiment of the engine and gearbox in one unit and one casting incidentally. The Clyno gudgeon pin is now secured in the connecting rod instead of the piston. By this means 50 per cent. more bearing surface is obtained; it is claimed that little ends never need rebushing, its bearing having a life equal to that of piston and cylinder. Ball bearings have been replaced by Hoffman rollers wherever possible. The handlebars have been widened in order to afford greater command over the steering on treacherous roads. Next season's silencer is considerably larger, and the exhaust pipe from engine and that running from silencer to rear of machine is 1½ in. diameter.

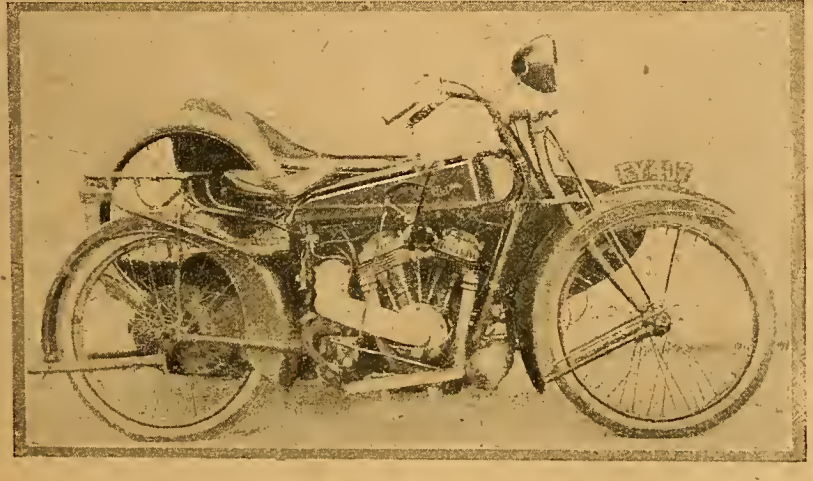
The 8 h.p. sidecar combination is an excellent proposition. Finished in grey with black wings, equipped with every conceivable refinement, including electric lighting and horn, it suggests speed and luxury at all points.

The engine has detachable cylinder heads, which practice allows of perfect machining and simplifies carbon removal, and connecting rods have cage roller bearings, the mainshaft bearings being plain. The pistons have three rings, and the middle portion of skirt is reduced to lessen friction. Valve tappets are held against their valves by springs to reduce clatter.

The carburetter is an Amac single-lever. A Lucas Magdyno supplies ignition and lighting. The gearbox is Clyno's own design of the constant-mesh sliding-dog clutch type. By the removal of the cover plate all mechanism may be taken out for cleaning purposes. Lubricant is pumped to the engine mechanically through an adjustable sight feed on the tank. A hand pump is provided as a stand-by and for the possibility of an emergency or gearbox lubrication.

The transmission is by roller chains with mechanical spring shock absorber on the engine shaft, all soundly protected. The spring frame has its centre portion sprung on two quarter-elliptic springs attached to its spring bracket. Radii centres are provided with phosphor-bronze bushes, and spring pins are specially hardened.

The mudguards are large, and dome leg shields supplement weather protection. The tank holds 2¼ gallons of fuel and 3 pints of oil. The wheels are the famous Clyno detachable and interchangeable, having voiturette rims and 28 in. by 3 in. Dunlop rubber-studded covers. The sidecars are thoroughly well appointed on spring chassis. Cee springs support the body, in which is carried the accumulators.

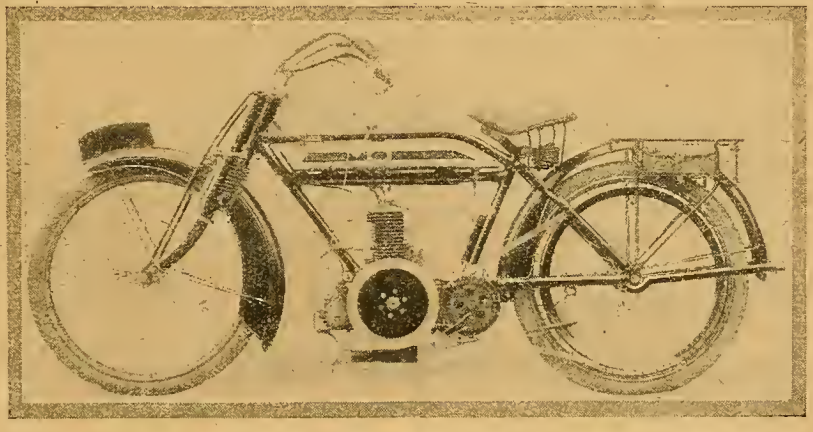


The 8 h.p. Clyno combination is a real "post-war" machine.

Stand No. 102.
Bordesley Engineering Co., Ltd., New Bond Street, Birmingham.

ON this stand are shown four models of the well known Connaught motorcycle. These are the Miniature, which sells for £52, the two-speed Miniature, which sells for £60, or with kick-starter and clutch £70, the Standard, £57, and the two-speed Standard, £65, or with clutch and kick-starter £75.

The two Miniature models are fitted with a Connaught two-stroke engine, of 75 mm. bore and 70 mm. stroke; 24 in. by 2 in. Dunlop tyres are fitted, and a ¾ in. Dunlop belt. Druid spring forks, Amac or B. and B. carburetter, and Leatheries or Lycett's saddles are standard. The finish is in black, the tank being enamelled aluminium, with green panels, lined red. Albion or Sturmey-Archer gears are fitted in the two-speed model.



The new "Baby" Connaught, which has 24 in. wheels. A larger edition is made with 26 in. wheels.

The two Standard models have 2½-3 h.p. Connaught engines, of a cubic capacity of 293 c.c. The tyres in this case are 26 in. by 2 in., and Amac or Senspray carburetters are optional. Two aluminium footboards are fitted, and the gear ratio is 5 to 1, instead of the 5½ to 1 of the Miniature models. The tank on the Standard model is black with red panels, having a capacity of 1⅜ gallons.

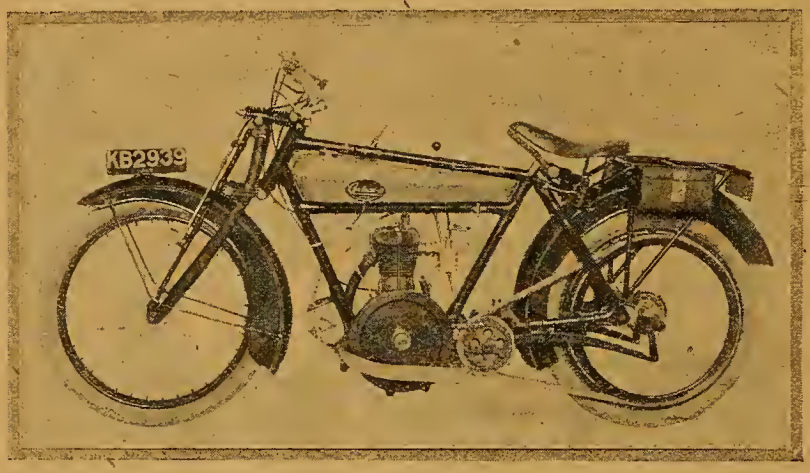
It will be remembered that the Connaught was the pioneer of the petroil lubrication system, and this is still retained, the results being very satisfactory. The special aluminium manifold attachment for the induction and exhaust pipe is cast in one piece, the inlet port being placed immediately below the exhaust port.

This system has a double advantage, the incoming gases being heated by the exhaust, and the exhaust gases being cooled by those incoming. By this arrangement the annoying "four-stroking," so common to two-strokes, is almost obviated. The device is one of the Connaught patents, and is employed, in a modified form, under royalty, by many of the best-known two-strokes at present on the market.

Corona Junior--Coulson Range—Diamond.

Stand No. 32.
Meteor Manufacturing Co., Ltd., 98, Tollington Park, London, N. 4.

THREE Corona Junior single-cylinder machines are exhibited here--a 2¾ h.p. model, a 4 h.p. solo, and one of heavier make, of the same horse-power,



The 2¾ Coulson B, fitted with Blackburne engine and spring rear wheel.

for sidecar work. The most interesting feature of these motorcycles is the construction of the engine. The crankcase and cylinder are made from cast-iron, and are in one piece. A removable cylinder head is fitted, and the crankshaft is of the one-piece variety, and mounted on heavy ball bearings.

An automatic lubrication system is employed on all models, consisting of a cogged wheel pump, which draws oil from the sump situated beneath the crankcase, and forces it along ducts into a trough into which the big end dips. Side-by-side valves are employed, and the tappets are set at an angle of 5 degrees. The cams work direct on to the tappets, the intermediate rockers being found unnecessary when the tappets are inclined at this angle.

Two internal-expanding brakes are fitted, both on the rear wheel. The wheels, which are fitted with 26 in. by 2½ in. tyres, are provided with knock-out spindles. All three models are equipped with E.I.C. magnetos and Capac single-lever carburetters.

The front fork is of particularly novel design. Near the lower extremities a cylinder, slotted on its underside, is placed horizontally on either side of the forks; this contains two coil springs. A large ball is situated between the two springs, and is connected to the front wheel by means of a bell crank lever, pivoted at the end of the forks. The machines are finished in a rather unusual way, the tank is striped black and white.

Stand No. 16.
Coulson Eng. Co., Ltd., Albion Street, King's Cross, London, N. 1.

THREE models of the Coulson motorcycle are shown at this stand, comprising the 2¾ h.p. standard Coulson B, which is fitted with a two-speed gear, 2¾ h.p. Blackburne engine, and costs 85 guineas. A 4 h.p. sporting model of practically the same design, and fitted with a Blackburne engine and single gear with adjustable pulley, priced at 90 guineas, and also a light sporting two-stroke, the Coulson U, fitted with a Union two-stroke engine and having a single gear. The price of this is 57 guineas. The specification of each machine includes the Coulson patent spring frame and registered tank design, Lycett saddle, Dunlop tyres and belt, E.I.C. magneto, semi-T.T. bars, Pedley grips, and inverted levers.

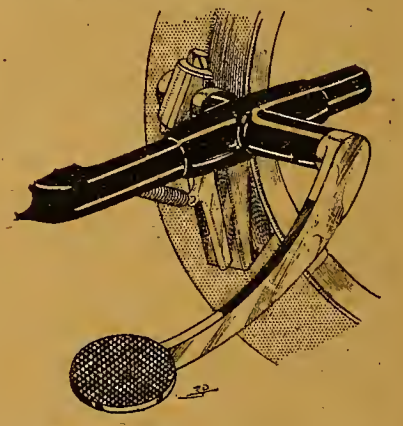
Stand No. 119.
D.F. and M. Mfg. Co., Ltd., Vane Street, Wolverhampton.

THIS concern is continuing with its extremely successful model of last year, eight samples of which are shown on the stand, in company with some half-dozen of their new model, which costs a little more and boasts one or two detail improvements, while retaining all the good points of its predecessor. Either may be had with a Villiers two-stroke engine and Sturmey-Archer two-speed gearbox, clutch and kick-starter, or with a four-stroke J.A.P. engine and Enfield two-speed gear.

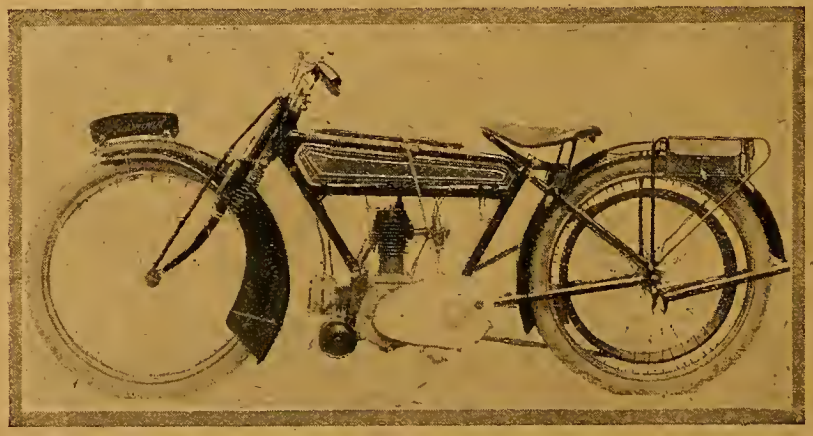
The rear brake is undoubtedly one of the simplest and most efficient ever fitted to a motorcycle. A lug is built in the frame, and holds a pin upon which the shoe moves. The pedal is merely an extension from the shoe, and is operated by the left heel, thus rods, toggles, and wires are eliminated, and the brake is reduced to elemental simplicity. Footboards are only fitted to the new model, the other having footrests.

The wheels are 26 ins. by 2¼ ins., fitted with Dunlop heavy rubber-studded tyres. The carburetter is the new A.M.A.C., and the magneto is a C.A.V. Druid spring forks take forward road shocks.

The forward down tube to the engine is duplex, and bolted up at the point of greatest strain, just under the head, by ⅜ in. bolts. The makers declare fracture to be an impossibility, as the bolts would have to shear first. On the Villiers model this frame further permits a straight exhaust pipe from the cylinder, which must be a slight advantage at speed. The new tank is larger, holding over 1¾ gallons of spirit, yet permitting of a saddle only 28 ins. from the ground.



The efficient Diamond rear brake.



The J.A.P. model Diamond, which has an Enfield gear. A Villiers machine can also be obtained with or without a gearbox.

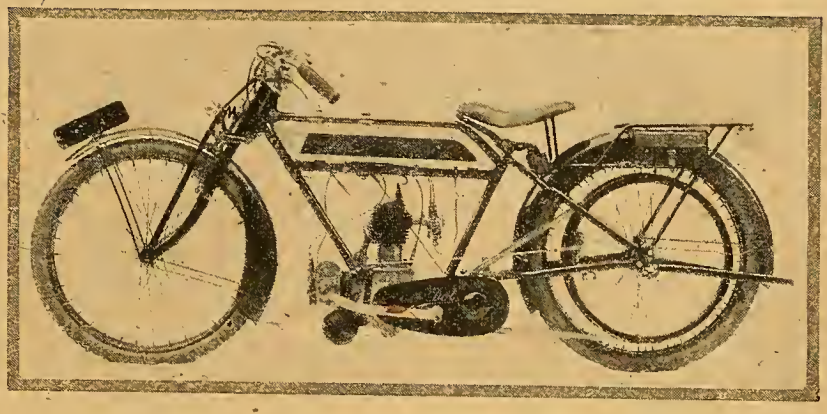
Two Dot Models—The Douglas Range.

Stand No. 113.
Dot Motors, 38, Ellesmere Street, Hulme, Manchester.

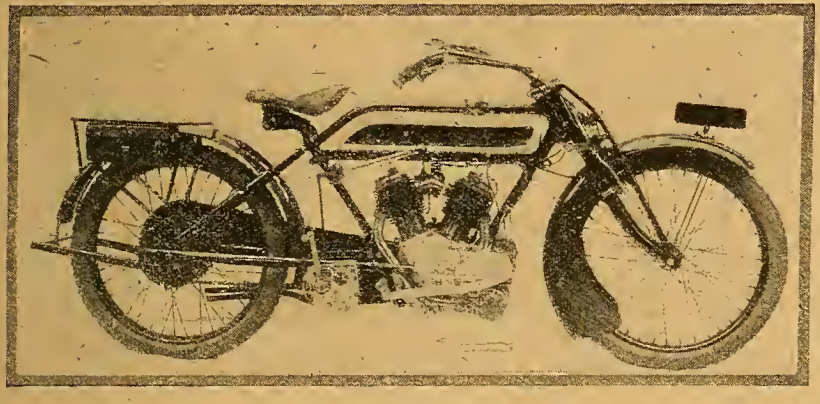
TWO models are shown, one a lightweight and one an 8 h.p. passenger machine. Both are fitted with J.A.P. engines, and are finished in similar style, with bright red frame and aluminium tank panelled red, which give them a distinctive appearance.

The lightweight is fitted with 2¾ h.p. four-stroke engine, Albion two-speed gearbox, and Saxon spring forks. The gearbox can be supplied either with or without clutch and kick-starter. Chain cum-belt transmission is employed, the foot brake working on the belt rim. The machine is supplied with 26 in. by 2¼ in. tyres, and scales 135 lb.

The passenger model has an 8 h.p. twin engine, Sturmey-Archer three-speed gear with kick-starter and hand-controlled clutch, and semi-enclosed all-chain transmission; 28 in. wheels are fitted, but the frame design is such that a low saddle position is obtained. The foot brake is of the internal-expanding pattern, operating in a separate drum on the back wheel. Saxon forks are embodied.



The Dot lightweight is a particularly attractive little machine. It has 2¾ J.A.P. engine.



Finished in bright red the 8 h.p. Dot is a handsome and sturdy sidecar mount.

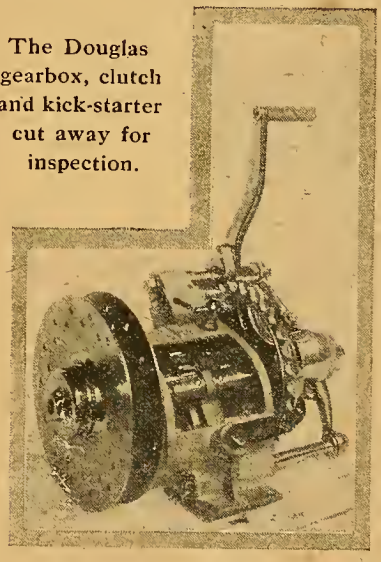
Sidecar lugs are built into the frame, and the sidecar supplied for the machine has a very rigid chassis, with four-point attachment and a body of handsome appearance, very roomy, and with bulbous back containing a large locker, suspended on leaf springs. The total weight of the combination is 550 lb., and like the machine, the sidebar body is finished in bright red and is very handsomely equipped throughout.

Stand No. 76.
Douglas Motors, Ltd., Kingswood, Bristol.

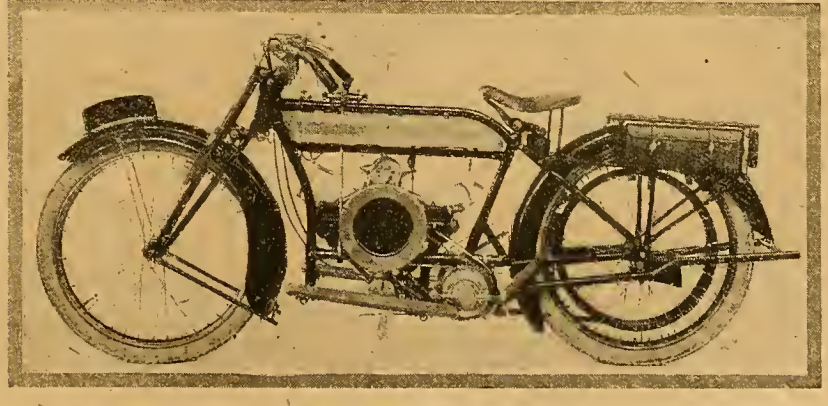
AN attractive display of Douglas models is staged, including the popular 2¾ h.p., the 4 h.p. sidecar combination, and the 3½ h.p. model which incorporates a spring frame.

It will come as a very great surprise, however, to the majority of Douglas enthusiasts to learn that it is not the intention of the concern to market the 3½ h.p. for 1920. This is due to the fact that orders for 2¾ h.p. and 4 h.p. models already booked up will more than cover the whole of the concern's productive resources for the coming season. In addition they have been compelled to cut out other existing models, and the A type T.T. 4 h.p. and the T.T. 2¾ h.p. have been entirely deleted from their programme.

The 2¾ h.p. model is now only supplied with a three-speed gear and a handlebar-control clutch of the plate type described at length in *Motor Cycling* a little earlier in the year. The latter is highly efficient, and it is a fact that it may be slipped almost indefinitely without any danger of burning. The frame



The Douglas gearbox, clutch and kick-starter cut away for inspection.



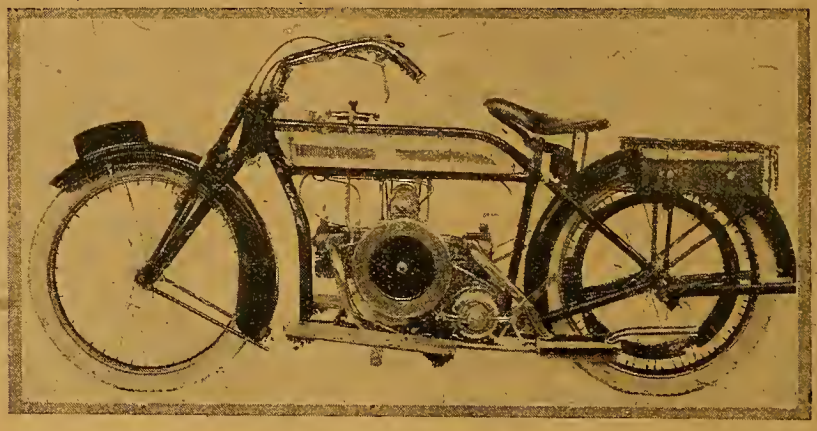
The popular 2¾ h.p. Douglas is now only supplied with three-speed gear and clutch.

More Douglas Details—Undertrays Standard—Excellent Fork Design.

of this model has been entirely redesigned for the coming season. Steel stampings for the lugs have now displaced the malleables previously used. The back stays and back forks have been widened to permit the use of large-section mudguards as extensive side valances. The new fork, which has also been described at length in *Motor Cycling*, is now fitted as standard, and adds very much to the whole appearance of the machine. It should be remembered that hardened and ground bearings and thrust washers are used throughout, and means are provided whereby lateral movement can always be taken up.

Douglas forks are of a slightly different shape for 1920.

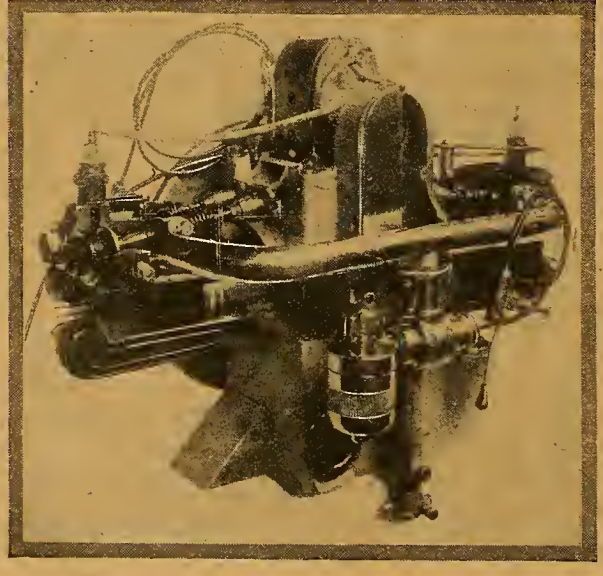
A minor detail, and one that will be much appreciated, is the use of a larger driving chain from the engine to the countershaft gearbox. This is now $\frac{5}{8}$ in. by $\frac{1}{4}$ in., and, so far as size is concerned, is interchangeable with the 4 h.p. machine.



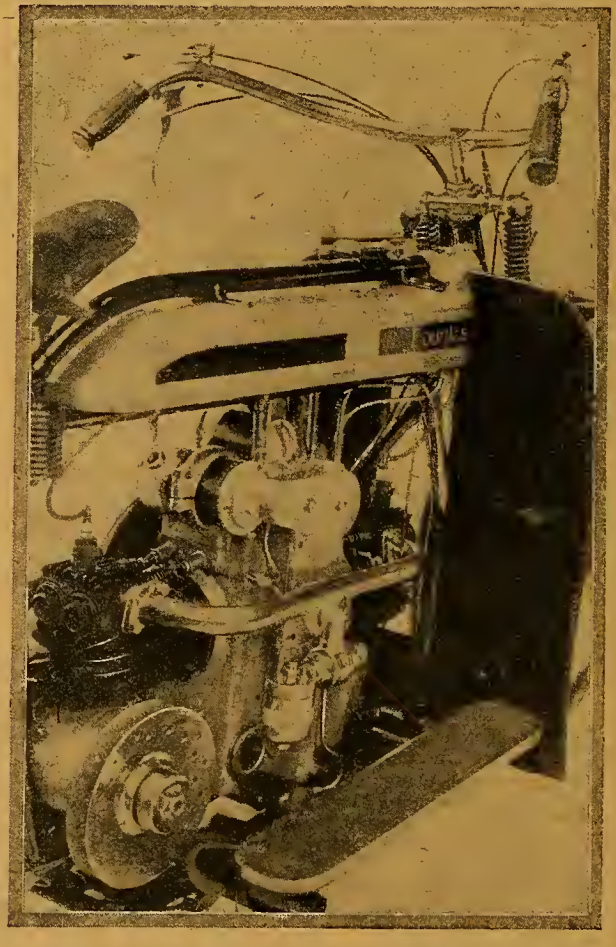
The 4 h.p. Douglas is a very familiar sidecar machine, particularly to ex-service riders.

The undertray, which was a noteworthy feature on the machines which recently went through the A.-C.U Six Days' Trial, is now fitted as standard, and will save no end of trouble in keeping the engine, gearbox and clutch in respectable condition. For a small additional charge a pair of patent leather leg shields, complete with clips, can also be supplied.

Footrests have now entirely disappeared on all models, and the well-known

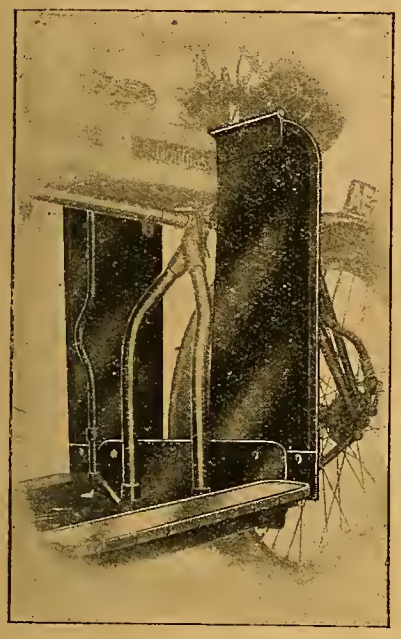


Sectional power units of all Douglas models are on view, forming a very interesting exhibit.



Undertrays are standard on all Douglas models. Note also the dynamo position and single-lever carburetter.

The Spring Frame Edmund—A New 3½ h.p. Two-stroke.



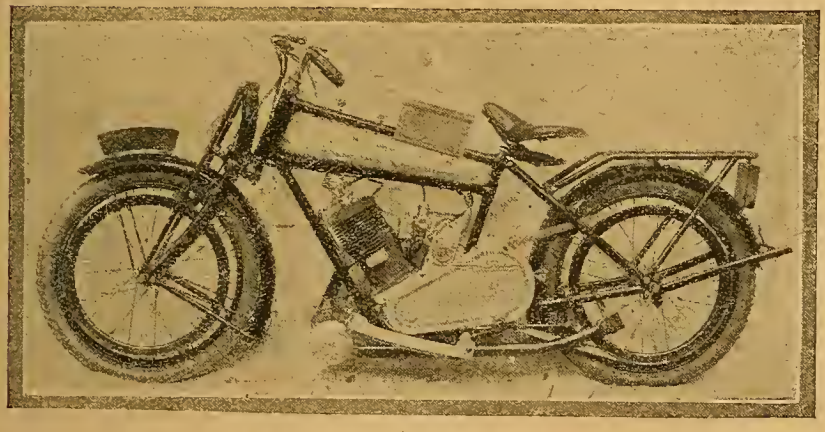
Douglas leg and undershield.

Stand No. 33.

Dunford and Elliott (Sheffield), Ltd., 96, Bath Street, Birmingham.

MESSRS. Dunford and Elliott of Birmingham, are exhibiting an example of their new Dunelt motor-cycle. This machine is fitted with a 3½ h.p. two-stroke engine of original design. By the use of a two-diameter piston it is possible to send through the transfer passage into the cylinder a charge greater than the capacity of the cylinder, this being accomplished by the bottom of the piston sucking into the crankcase a volume of gas in excess of that swept by the upper or working part. Actually, the displacement of the lower portion is 770 c.c., and that of the upper portion 500 c.c. Thus a much better scavenging effect is secured than is usually the case, and no "dead" gas is left in the cylinder to dilute the succeeding charge, in addition to which the piston is to a certain extent cooled by a portion of the fresh charge being circulated around the lower port of the working piston.

A rigid frame is employed, with sloping top tube, and spring forks of special design. A two-speed gear of the expanding ring type, with no gear wheels, is located at the countershaft, and is driven from the engine by two enclosed roller chains. A clutch and kick-starter are incorporated in the gearbox. Final drive to the back wheel is by rubber belt. Very wide domed mud-guards are fitted, also aluminium foot-boards. The wheels are interchangeable, and both front and back brakes work on the belt rims. 26 in. by 2½ in. tyres are standard. The price is to be about £70.



The only big single two-stroke—the Dunelt, of 3½ h.p.

Stand No. 99.

Edmund, C., and Co., Ltd., Crane Bank, Chester.

THE outstanding feature of all the Edmund models—of which three are shown—is the Edmund patent spring suspension of saddle and footboards.

The principle of its construction is that the top frame tube pivots at the steering head, and, carrying the tank and saddle, is supported at its rear end by two laminated springs, which are fixed in such a way as to be adjustable to suit different riders' weights, to the rear carrier stays. Short coil springs, acting as shock absorbers, are placed at the lower end of these stays. The saddle is inter-connected with the footboards by means of an extended saddle pillar passing down the seat tube; thus the rider is insulated from road shocks, whilst the main frame, carrying engine and rear wheel, remains rigid, and demands no special sidecar chassis, should one be fitted. The tank, being on the sprung portion of the frame, is relieved of a great deal of strain and vibration, petrol and oil being conveyed to the engine through pipes of flexible petrol-proof rubber tubing, as is commonly employed in aero work. The spring forks are of the Druid type.

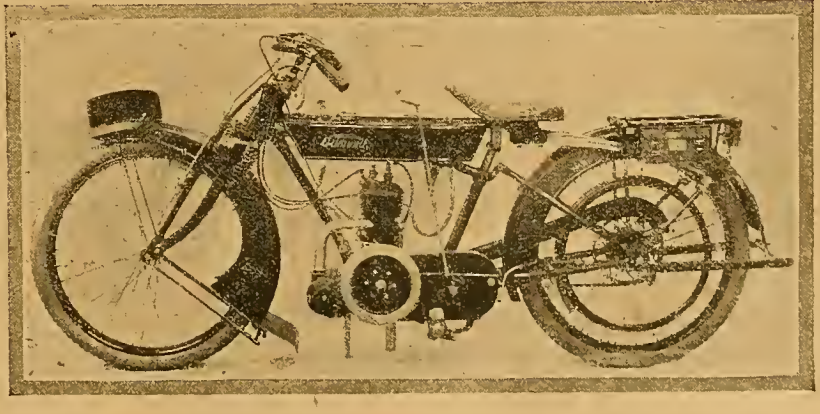
The foregoing description applies equally to all three models, the difference between the types being in engine and gearbox. Model 1 has 2¾ h.p. J.A.P. engine and Enfield two-speed gear, with all-chain cush drive; Model 2 has similar engine, but the gearbox is a two-speed Burman with clutch and kick-starter and chain-cum-belt transmission; whilst Model 3 has a 2¾ h.p. two-stroke Union engine, with the same gear and transmission as Model 1.

brass-bound linolenm-covered footboards will be fitted to all types. There is a slight alteration in the shape of the tank.

At the time of writing, the price of the 2¾ h.p. model W20 has been fixed at £90 for the coming season.

The 4 h.p. machine known as model B20 has not been altered very much from the type which proved so satisfactory in war service. Perhaps the biggest change is the incorporation of the plate clutch. As fitted, this is foot-controlled, but it can be converted to a handlebar control with a very little trouble.

The sidecar body to go with the 4 h.p. has now been vastly improved. It is nicely finished in saxe blue and upholstered in a very much darker shade of the same colour. The price of the 4 h.p. model complete with sidecar and undershield will be £145, which should appeal to those desiring a first-class outfit.



On the Edmund the saddle is supported on a well-sprung sub-frame.

The New Enfield Models—Machines for the Lady Rider.

Stand No. 72.

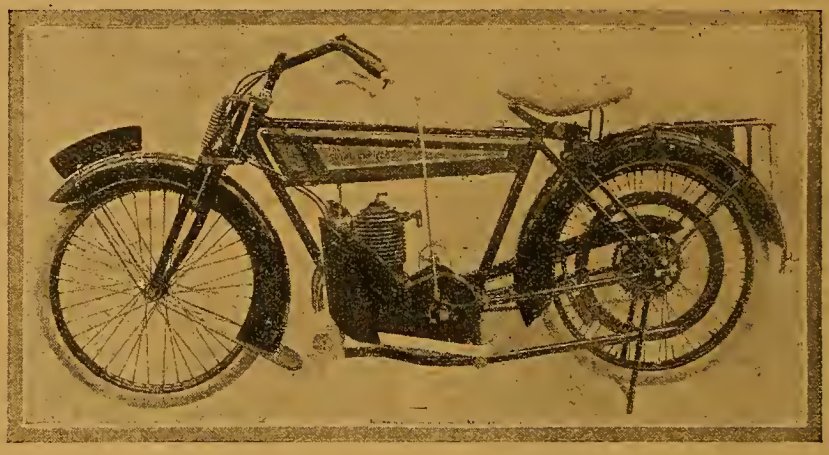
Enfield Cycle Co., Ltd., Redditch.

THE Royal Enfield machines on view at this stand differ only in minor detail improvements from previous models. The 2¼ h.p. two-stroke model is one of the smartest little lightweights on the road, and with its simple Enfield two-speed gear it is capable of going anywhere that the ordinary rider will care to take it. Unlike the larger models this machine has a sloping top tube which affords a very low saddle position. The efficient spring forks and large aluminium footboards combine to render the machine very comfortable, while the all-chain drive makes it essentially a no-trouble mount.

The "Baby" Enfield should make a special appeal to novices, for its control is as simple as it is possible to make it. The ignition is fixed, and, as the carburetter is automatic, only one lever appears on the handlebar.

Four examples of the Royal Enfield combination are shown. The power unit is the famous J.A.P. and does not call for further comment. The Enfield two-speed gear is, of course, employed with all-chain drive, the front chains being neatly encased in a cast aluminium cover. The charm of the Enfield two-speed gear lies in its simplicity of operation, each gear being engaged by means of an expanding ring clutch. This renders the machine very suitable for a novice.

The hand-starting arrangement is simple and the handle folds out of the way of the driver's leg. The large tank is provided with filler caps of large diameter and the sight feed Benton and Stone lubricator. The carburetter now fitted is the new single-lever pattern A.M.A.C.



The 2¼ h.p. Enfield two-stroke is an ideal touring lightweight.

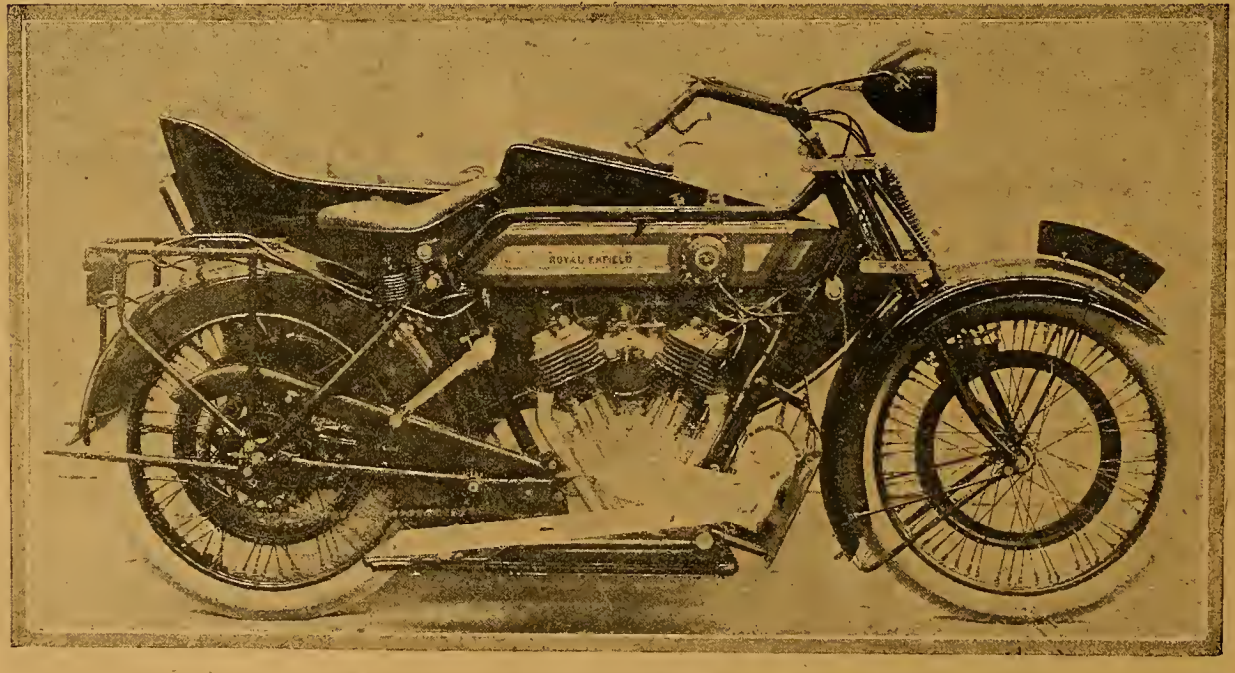
The four examples of this model shown are the standard Model 180, one with the Lucas Magdyno lighting set, known as Model 190, one with a tradesman's carrier with a large coach-built box carrier, and one with Lucas Magdyno lighting set and the Enfield hood and windscreen. The hood is of a new pattern, and when not in use folds back in the rear of the sidecar.

The windscreen is adjustable to any required angle and is locked in the chosen position by two wing nuts. To allow the sidecar door to open easily the screen is arranged to swing out of the way.

On those models which have the Lucas Magdyno fitted the switch is neatly accommodated in the offside of the tank, sufficiently far forward not to incommode the driver's leg. The handlebars are of the well-known Enfield pattern, and in conjunction with the low saddle position and long footboards give a very comfortable riding position, whatever the stature of the rider may be.

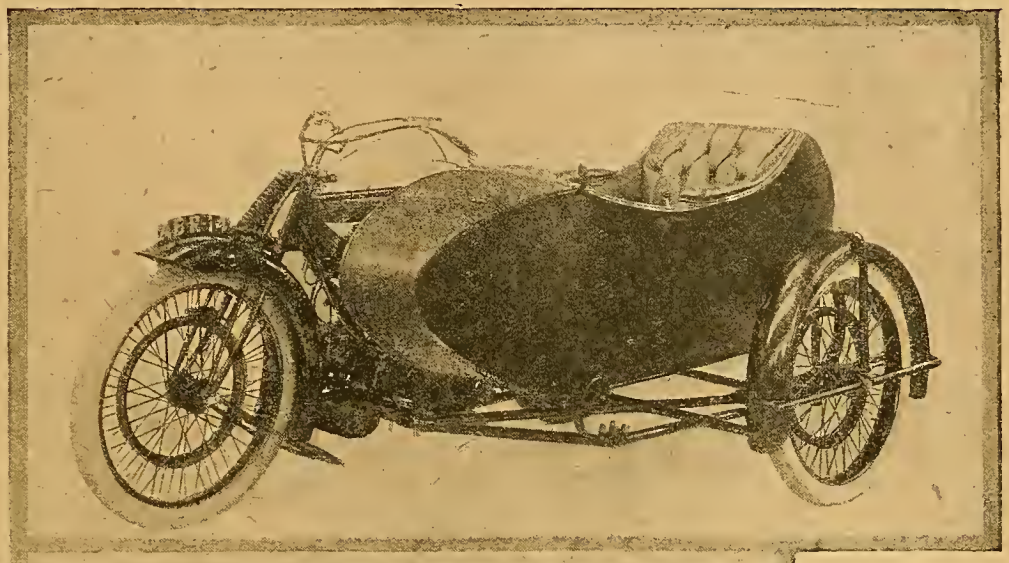
For this reason and the tractability of the big twin the Enfield has always been popular with lady riders, and this year its increased ease of control due to the single lever carburetter should result in its being more popular than ever with the fair sex. As may be seen, the wheels are now shod with 700 mm. by 80 mm. tyres, and this not only increases the riding comfort very considerably, but minimizes the chances of tyre troubles.

A notable absentee from the Enfield exhibit this year is the 3 h.p. twin.

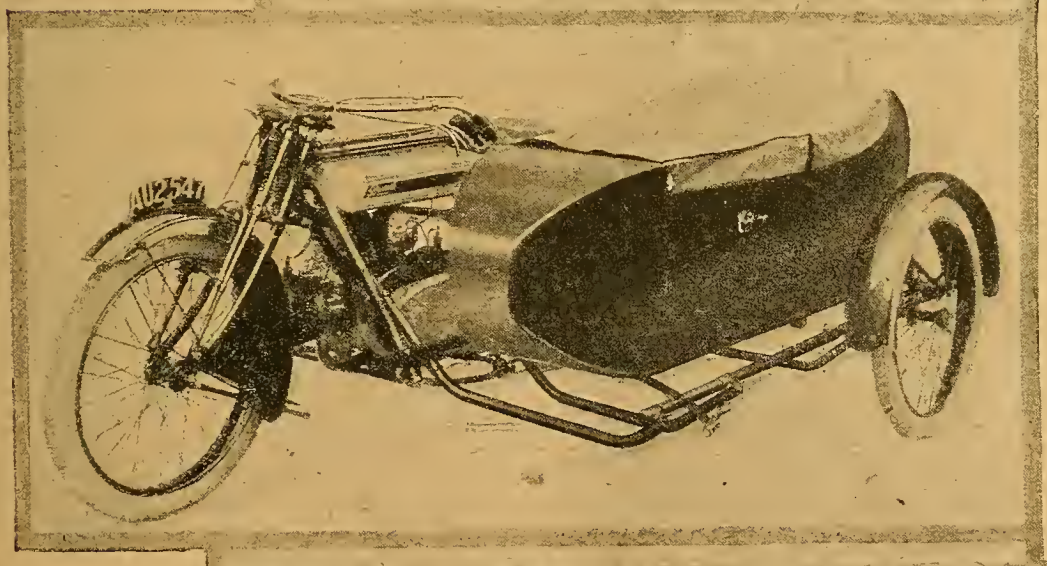


The 6 h.p. Enfield is now fitted with Lucas Magdyno and 700 by 80 mm. tyres.

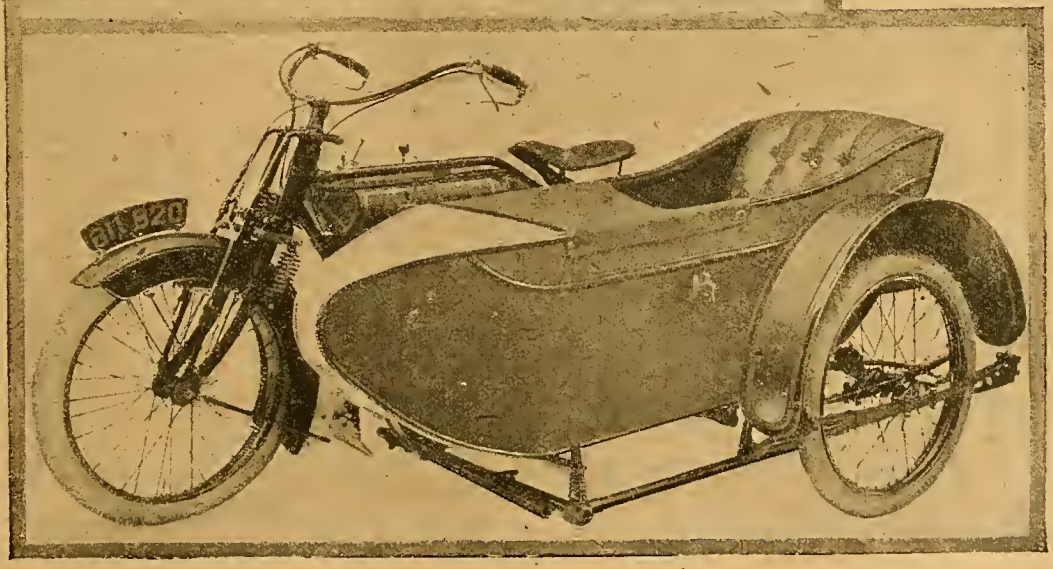
TWIN PASSENGER MACHINES



The new 6 h.p. twin B.S.A. is fitted with a mechanical lubrication system, 28 in. by 3 in. wheels, are standard, and the mudguarding is particularly well carried out.



The 5-6 h.p. Brough, one of the few horizontally-opposed-engined sidecar machines. The specification includes Brampton forks and Sturmey-Archer gear.

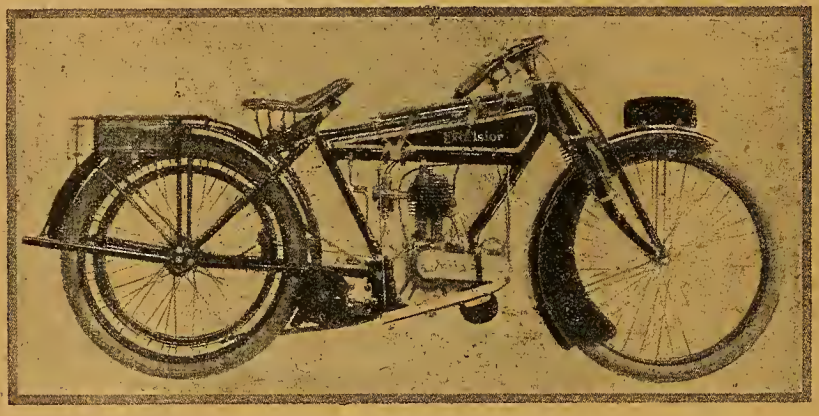


The Bradbury is designed to withstand the roughest conditions. The power unit is a 6 h.p. engine constructed at the Oldham works

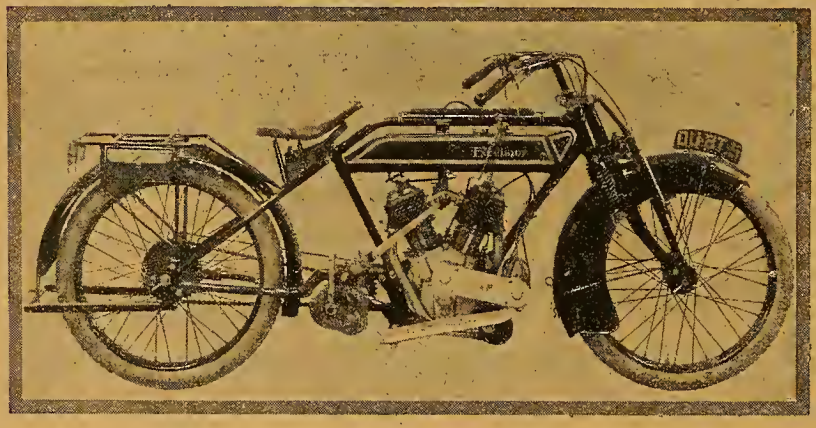
British Excelsior Lightweight and Heavyweight—American Excelsior.

Stand No. 51.
Bayliss, Thomas and Co., Ltd., King's Road, Tyseley, Birmingham.

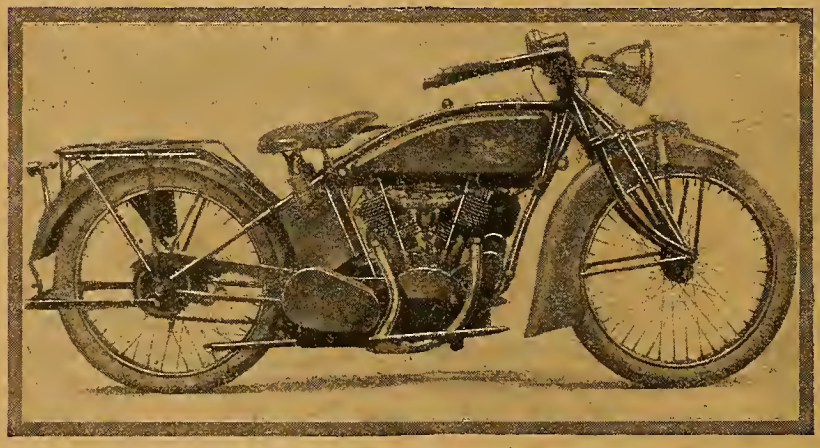
SEVEN interesting machines are found on this stand, and interest centres round the big sidecar outfit. This is the 1920 model, with 8 h.p. J.A.P. engine, three-speed Sturmey gearbox, and chain drive. The detachable wheels are a great feature, and are carried out in a sound engineering manner. The rear brake, which is of the internal-expanding type as fitted to cars, is very powerful and is Ferodo lined. The strong wheels with hubs machined from solid billets of steel are worthy of note. The large tank and many refinements are indicative of the whole nature of the machine, strength and attention to detail. The roomy sidecar is the admiration of the fair sex. The price of the outfit is £162 10s., and the solo machine is £132 10s. with either 6 h.p. or 8 h.p. The lightweights shown are the two-speed, clutch and kick-starter models, with 2½ h.p. J.A.P. engine, at £68 10s., or Villiers 2½ h.p. two-stroke at £64 17s. 6d., and similar machines with plain two-speed gears at £62 10s. and £58 16s. respectively. Chain-cum-belt drive is employed on all four lightweight models, and the standard Excelsior finish of black with blue lining on the tank is applied to all models. The lightweights bear as many refinements as the larger model. The arrangement of the brake pedal stop is very neat, for a cam on the brake pedal butts against the footboard. The wheels on the lightweights are 26 in. by 2¼ in., while the big twin has 28 in. wheels, which render it a particularly comfortable machine.



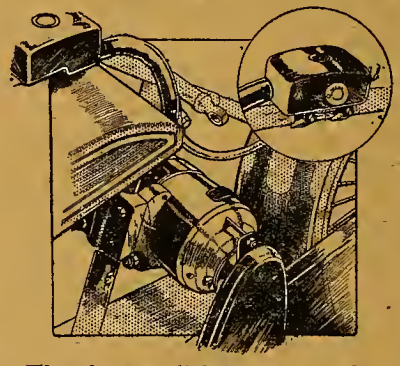
The 2¾ h.p. four-stroke British Excelsior lightweight.



A typical Britisher—the 8 h.p. J.A.P.-engined Excelsior sidecar mount.



Typical American practice—the 10 h.p. Excelsior, fitted with Midco ignition-lighting system.



The dynamo lighting set on the British Excelsior.

Stand No. 21.
Melchior, Armstrong and Dessau (London), Ltd., 14, Great Marlborough Street, Oxford Circus.

THREE Henderson and three Excelsior machines are exhibited at this stand, comprising in each case a standard model, an electric model, and a sidecar combination. The electric model Excelsior incorporates the Midco magneto generator and storage battery, while the Remy generator figures on the electrically-equipped Henderson. The latter machine, although only introduced to this country just before the war, has attained considerable popularity with British motorcyclists. Its salient features are dealt with in a paragraph on another page. To return to the Excelsior, this incorporates the "oversize" power unit so popular across the water, and as such should appeal to speedmen and sidecar enthusiasts. Overhead inlet valves, mechanical lubrication, and a Schebler carburetter are its main characteristics. While not so well known perhaps as one or two other competitive American motorcycles, it is rapidly winning an excellent reputation for itself, and the careful observer will notice the excellence of design and beauty of finish displayed.

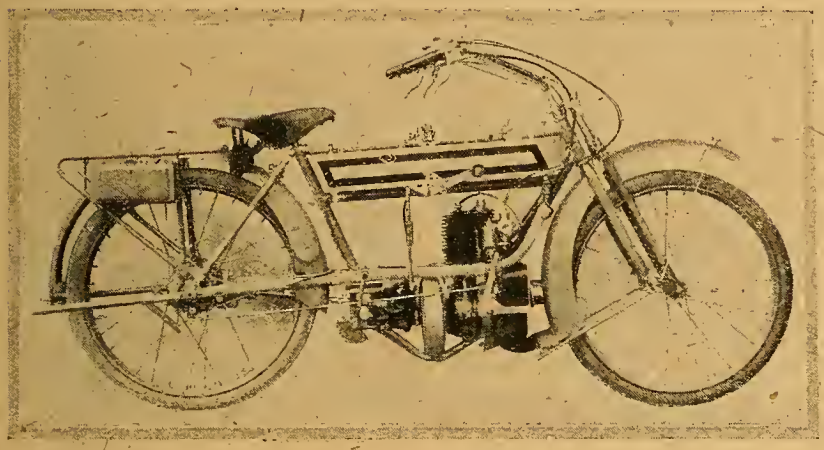
F.N.s Once Again—The Harley-Davidson Sports Model and Sidecar Combinations.

Stand No. 54.
F.N. (England), Ltd., Kimberley Road, Willesden Lane, London, N.W. 6.

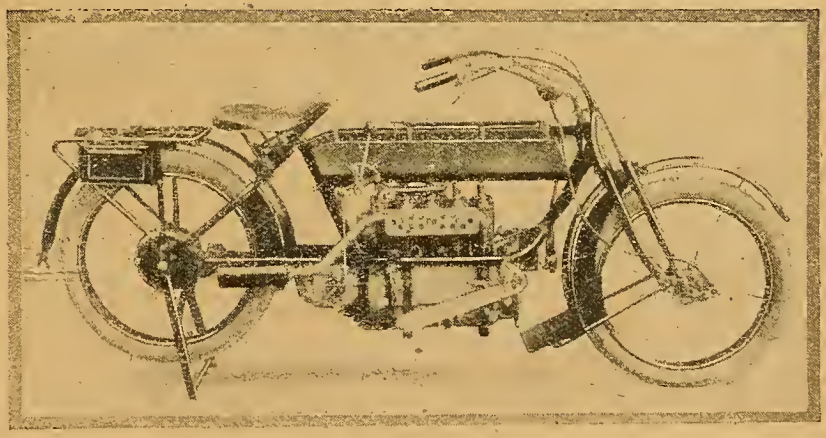
THREE 2½ h.p. lightweights, two 7 h.p. four-cylinder machines, and one 7 h.p. four-cylinder sidecar combination are to be found on the F.N. stand. Owing to the fact that the Belgian factory had been in the hands of the Germans during the war, it has been impossible to incorporate many new features on these machines, and their specification differs only slightly from the 1914 models.

As is well known, both models are built throughout on car lines. The lightweight has the engine placed crosswise in the frame, which has a duplicated lower member. A plate clutch is provided, and the drive is taken through a two-speed gearbox, and thence by bevel gears and a shaft to the rear wheel.

The 7 h.p. model follows closely on these lines, save for the fact that a three-speed gear is provided. An innovation on this model is the automatic lubrication system. This consists of a rotary centrifugal pump, driven at camshaft speed, which keeps the troughs into which the big-ends dip filled with oil, and pumps oil from the tank when required. The price of the 2½ h.p. machine will be about £85, and the 7 h.p. £135, or as sidecar combination £175.



The 2½ h.p. F.N. lightweight is a handy little mount which has pleased numerous owners.



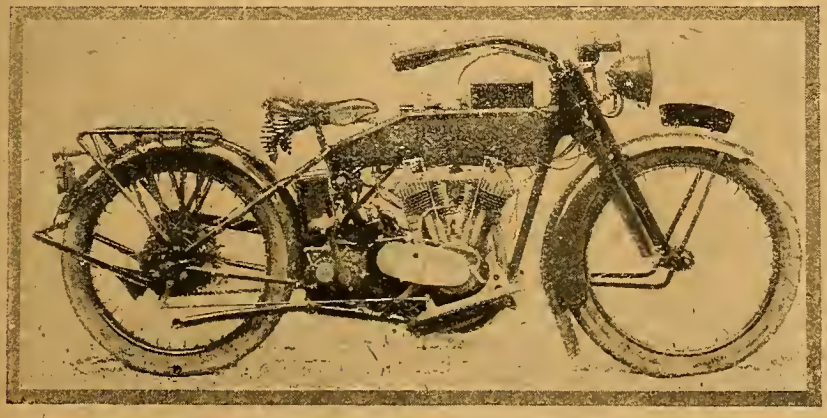
Welcome back!—The popular four-cylinder F.N. reappears.

Stand No. 117.
Harley-Davidson Motor Co., Ltd., 74, Newman Street, London, W.

HORIZONTALLY-OPPOSED twin enthusiasts will find much to interest them in the 4 h.p. Sports model Harley-Davidson, which makes its initial bow to the public at this year's exhibition. It will be remembered that the model was fully described by *Motor Cycling* earlier in the year.

It is an extremely well designed machine, and any suggestion of inaccessibility can be dispelled by a close inspection of how every vital part is so arranged as to be quickly get-at-able and removable. The inlet manifold and the gear drive of the three-speed box are deviations from standard English practice, and are especially noteworthy. The little twin still has its laurels to win in this country, but the reputation for excellence of material and workmanship gained by its big brother—of which several models are shown—will go far to help it on its way.

One model is shown coupled up to a light sidecar specially designed for it. The combination is attractive and will undoubtedly win over many users from previous devotees of the big single.



The 7-9 h.p. Harley-Davidson is one of the most popular American machines marketed in this country.

Of the 7-9 h.p. machines, both the standard (magneto) model and the de luxe (electrically equipped) model are staged. Undoubtedly the de luxe sidecar combination exhibited is one of the most handsome outfits in the hall. This company have realized what important factors comfort and elegance are in the choice of a passenger combination, and the coachwork displayed is equal to that incorporated in the finest cars. Probably the special body staged, on which the hood is of the disappearing variety, is the most luxurious which has yet been produced. The upholstered arms are so arranged as to fold back, thus disclosing a "well" on each side into which the hood collapses when not in use.

The excellent practice of staging sectional models of most of the important features of the machine is followed, and many accessories specially adapted for Harleys will also be found on the stand.

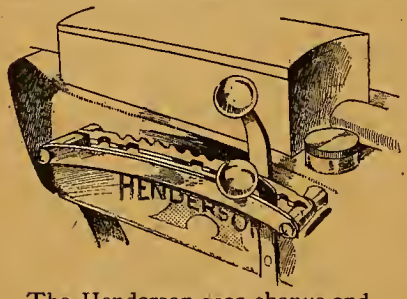
The Four-cylinder Henderson—Hobart.

Stand No. 21.

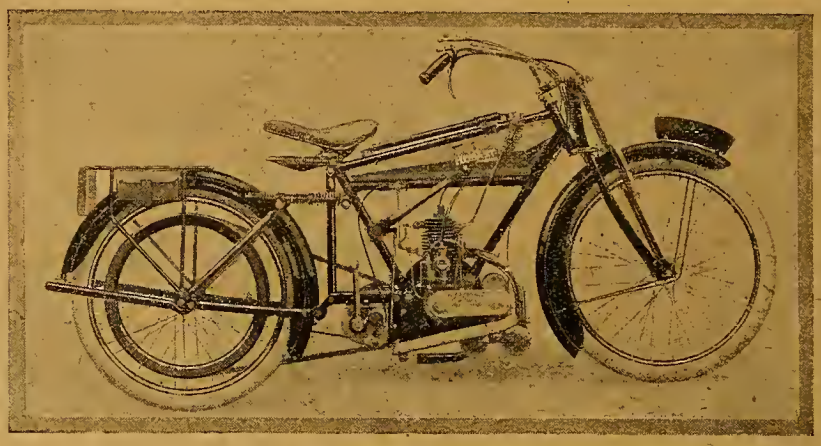
Melchior, Armstrong, and Dessau (London), Ltd., 14 and 14a, Gt. Marlborough Street, Oxford Circus, London, W. 1.

THE only serious competitor to the F.N.—the well-known four-cylinder Henderson—is shown on this stand. It is in every way a most interesting production, and apart from the sweet running qualities of its multi-cylinder engine, the fact that the latter is of larger cubic capacity than any English production should make the machine appeal strongly to sidecar enthusiasts who welcome a reserve of power.

Readers who are already acquainted with the salient features of the machine should look particularly for the new pattern front forks adopted for the coming season. These, being curved instead of straight as formerly, contribute very much to the graceful appearance of the machine, and the fact that the tank is now streamline in contour and has no sharp corners also adds to the general attractiveness. Another feature, which, to the best of our belief, is only employed by one competitive make, is the fitting of a ratchet to the brake lever, so that the machine can be left unattended with the brakes on and the clutch out. In common with most American machines, mechanical lubrication is employed, while there is a choice of models, these being obtainable fitted with either a Berling magneto or with a combined magneto and driving dynamo.



The Henderson gear change and handbrake ratchet.



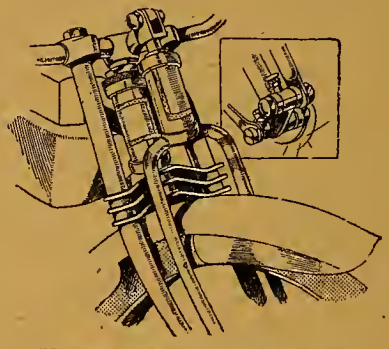
The two-stroke Hobart has a Villiers engine and spring frame.

Stand No. 106.

Hobart Cycle Co., Ltd., Coventry.

HERE we have four attractive lightweights, fitted with J.A.P. and Villiers engines, including a spring frame model. The Hobart patent spring frame, which has been under test continuously since 1915, has proved all the makers claimed for it, and may be considered seriously by those who desire a little more comfort on bad roads than is provided in the average motorcycle saddle. The stability and unity of the frame does not in any way depend upon the springs, and even in the event of the utterly impossible contingency of all the springs breaking at once, the machine would still be able to proceed.

As the company point out, two kinds of road shocks have to be provided against. Firstly, the violent, associated with potholes and ruts; and secondly, the less intense yet more frequent blows of badly-laid paving, stone setts, etc. Naturally, two sets of springs will be required to intercept both kinds of shock, and this frame meets them by a combination of stout springs having a good range of movement, but slow periodicity of action, and others very much weaker, but able to act very rapidly. All the spring mechanism is carried high out of the way of mud and dirt, while the journal bearing surfaces are of very generous proportions. Brampton spring forks are also fitted.

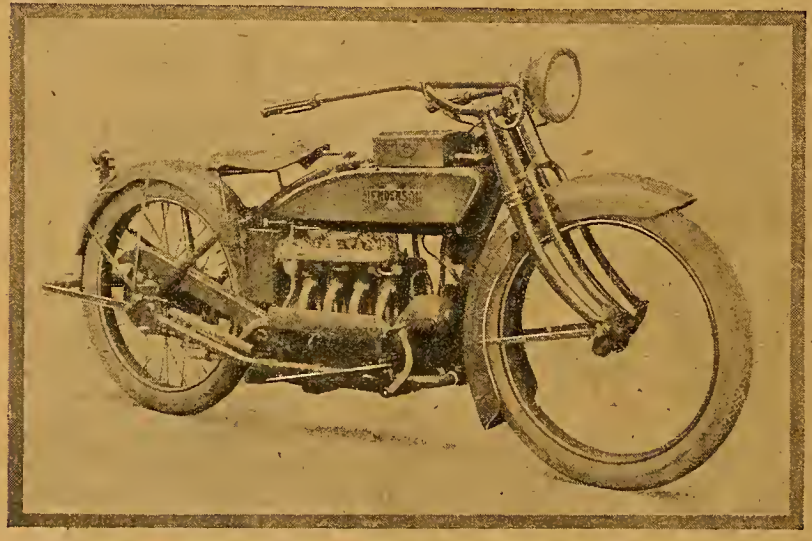


The Henderson fork spring is enclosed in a dashpot.

The rider's comfort is further studied by the provision of an X-L-All saddle and long footboards on all but the single-speed model. Those on the J.A.P.-engined machine are particularly commendable, having heel pieces and the upturned forward extremity.

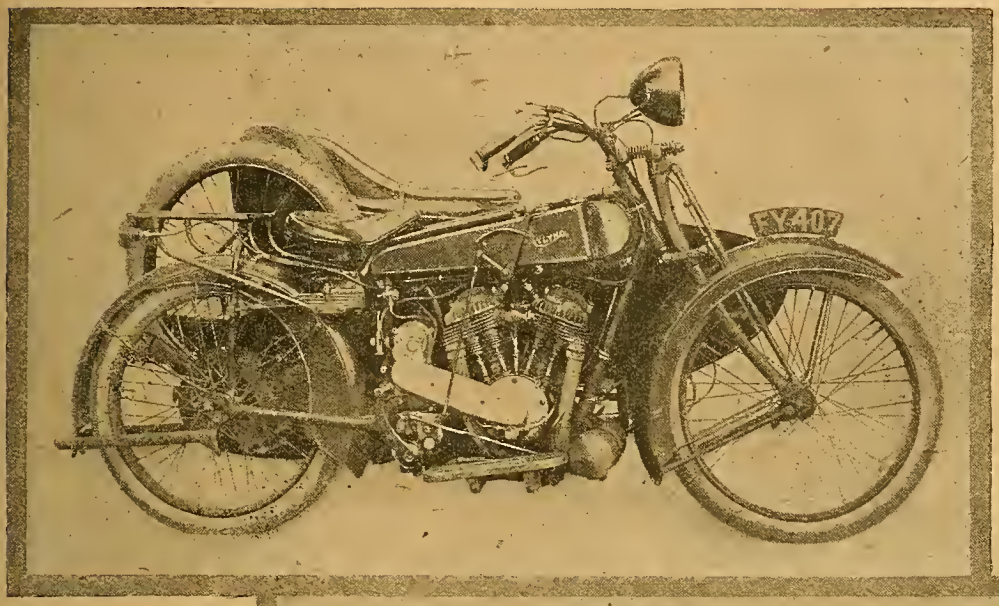
On the four-stroke and spring-frame models a Sturmey-Archer three-speed gearbox and kick starter are fitted, while the other two-speed model has a Chater-Lea gearbox, having two speeds but no clutch, and it really is doubtful whether these are necessary on such a handy little machine.

An Amac carbureter is used, and lubrication is by means of a sight feed drip oiler. The tanks are sloping and tapered, of pleasing lines, and have large glass-topped filler caps.



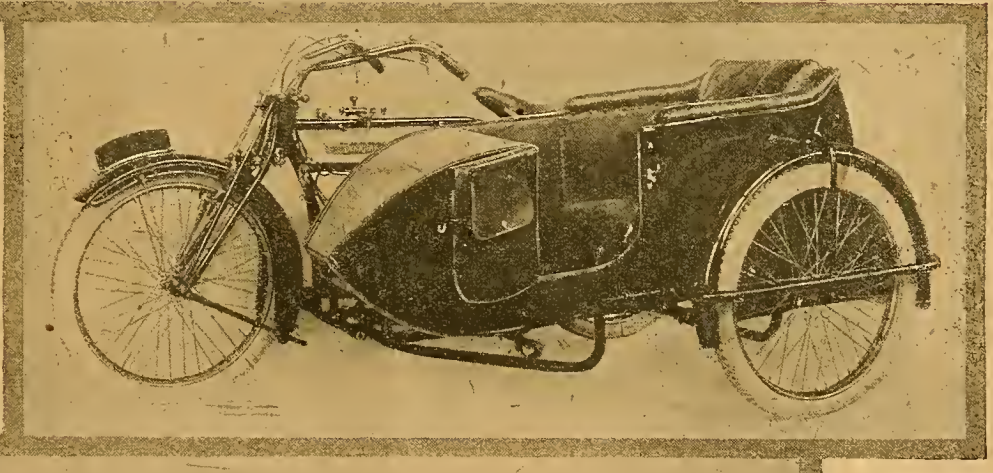
The Henderson now has a shorter wheelbase and neater lines.

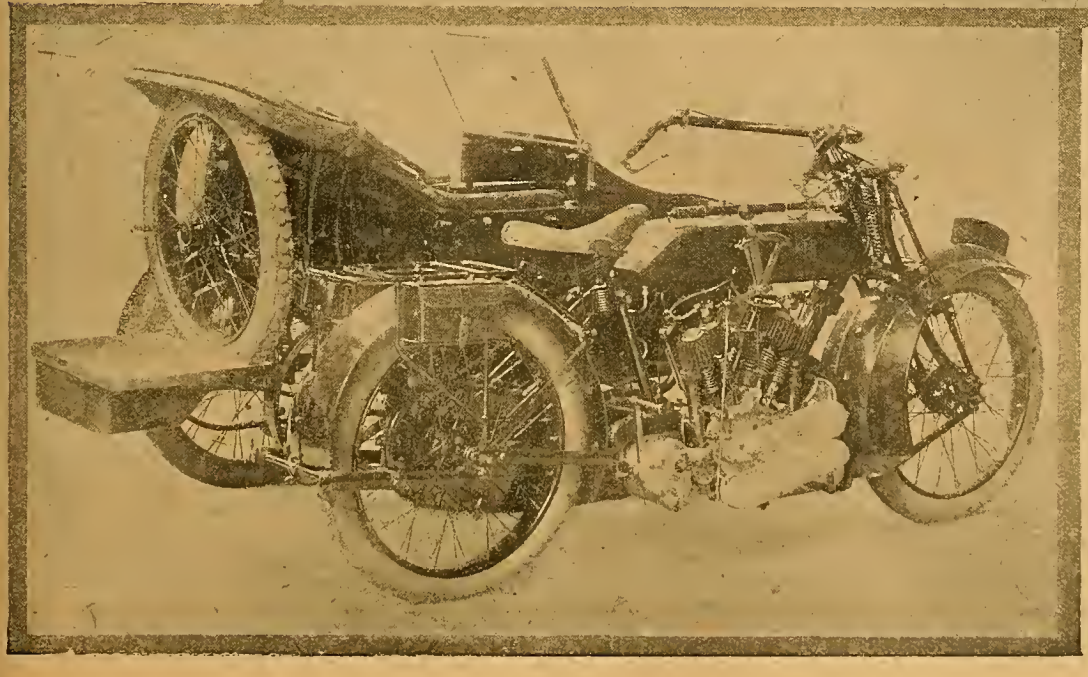
SIDECAR OUTFITS DE LUXE.



The 8 h.p. Clyno is rendered particularly comfortable by the 28in. wheels, spring frame and Brampton forks. All wheels are interchangeable.

The 4 h.p. Douglas. A successful example of the medium-powered twin opposed engine, first conceived by them.





The instantly detachable wheels, removable cylinder heads and saddle tank are distinctive features of the A.J.S.

Two Hazlewood Models—The Hobart Lightweight.

Stand No. 107.
Hazlewoods, Ltd., West Orchard, Coventry.

ON this stand are shown two sidecar outfits and a very sporting solo machine, practically the only difference in the two models being the pattern of the handlebars, the solo having wide T.T.-pattern while the sidecar outfits have the ordinary touring type.

The engine, a J.A.P. built specially to the order of Hazlewood's, has a cylinder capacity of 700 c.c., its dimensions being 70 mm. by 90 mm. The automatic model B. and B. carburetter produces the mixture, which is ignited by an M.L. magneto, chain-driven.

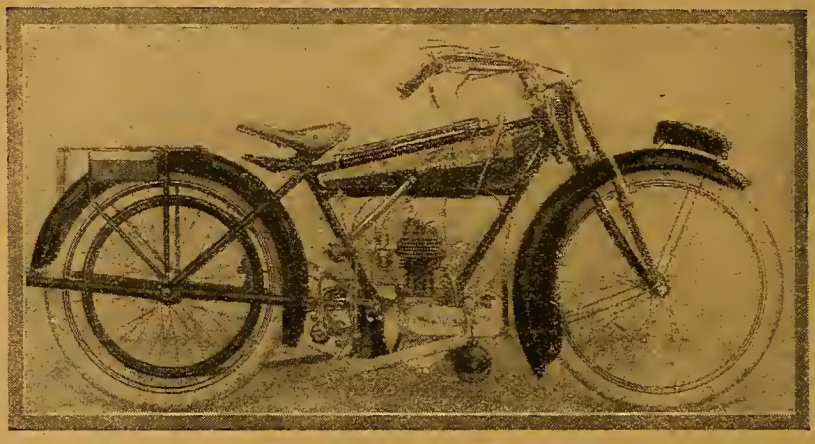
The gearbox is of Hazlewood manufacture, an exceedingly workmanlike job of sound design, and heavy but not clumsy construction, designed for a hard life under strenuous loads. It has three speeds, high and low gear pinions being constantly in mesh, and engaged by dogs attached to the sliding pinion. A kick-starter and clutch is, of course, embodied, the latter having cork insets and a very gentle action.

The transmission is chain-cum-belt, the large belt pulley on the gearbox being drilled and protected by the chain guards against bad weather, and should be subject to very little slip in the heaviest of rains. The silencer is very efficient, and has an extension to the rear. Its connections from the engine are flexible piping, helping towards accessibility in this region of the engine.

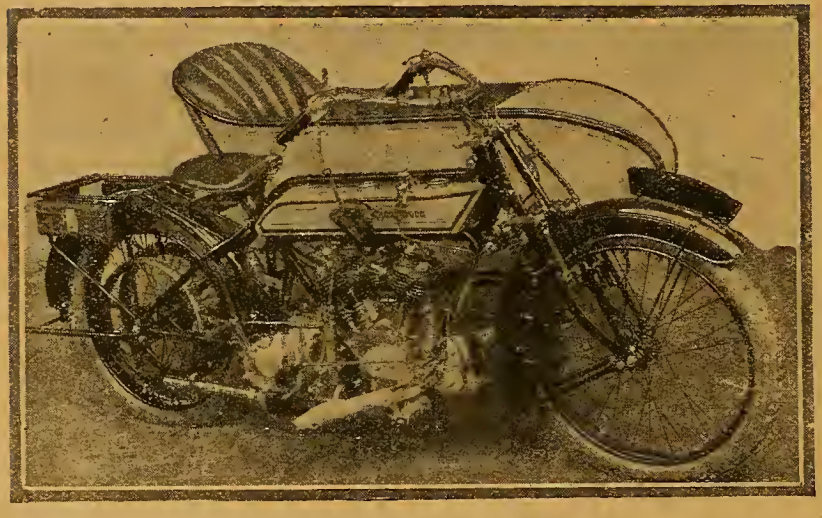
The design of the back brake should be noted. This is the compensating slipper type, Ferodo-lined, operating on a steel drum attached to the back wheel. Its operating rod is free from bends of any kind, and pierces the mudguard in order to provide a straight pull.

Hazlewood's consider their frames to be absolutely unbreakable, not a single instance of fracture having come to their notice. The tubes are all reinforced by spiral liners, and lugs for the sidecar are built up with the frame, while an additional strengthening piece is bolted up with the forward connection, providing an increased margin of safety at this vital point.

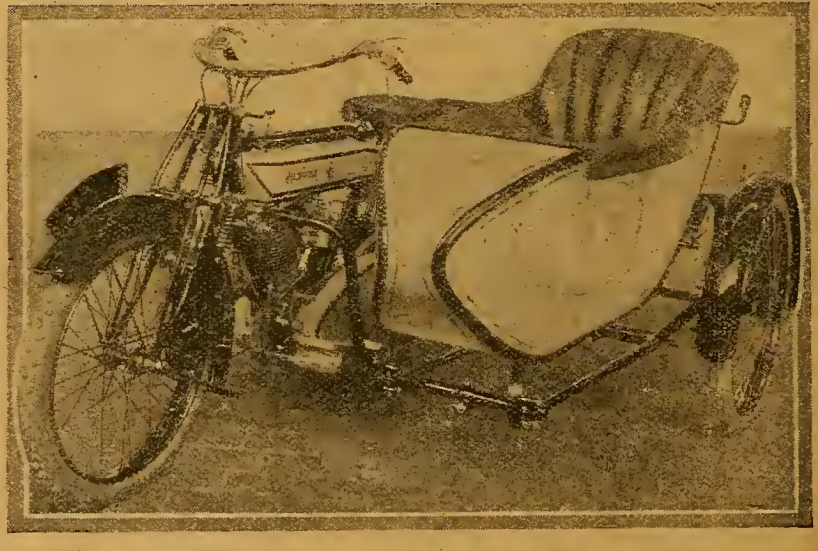
The tank capacity is 1¾ gallons of petrol and ½ gallon of oil, which enters the engine through a sight drip feed lubricator at its right-hand side. It is enamelled Hazlewood grey, with black and gold lines, and presents a very artistic appearance. The 650 by 65 mm. heavy Dunlop tyres are fitted to wheels built up with heavy-gauge spokes on stout hubs, having bearings specially designed with a view to the exclusion of water and road dust. The mudguarding is good, the forward guard having a deep valance, and the rear an extension on each side, one for intercepting the belt drum splashes and the other for mud carried round by the belt and flung upward. The long aluminium footboards provide several changes of position, and have heel pieces to prevent the feet slipping off on very bad roads. The sidecars shown on the stand are a Millford and a Canoelet.



The Hobart is a smart little mount, fitted with a 2¾ h.p. J.A.P. engine.



The 5-6 h.p. Hazlewood combination. The engine is a J.A.P. of special dimensions and 700 c.c. capacity.

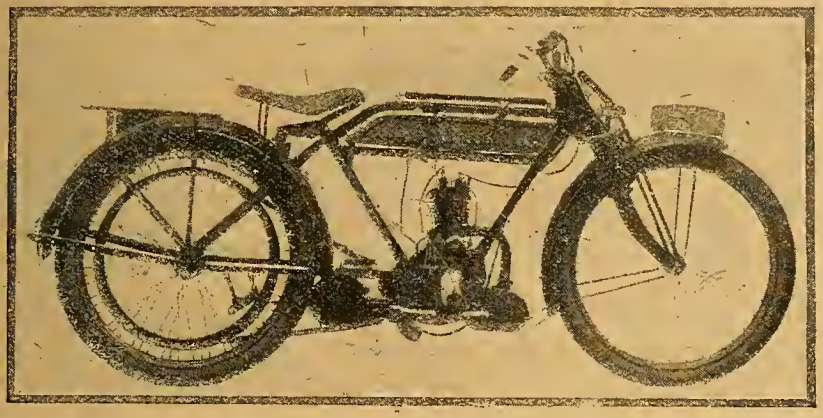


Another view of the twin Hazlewood combination.

Humber's Programme—A New Lightweight Two-stroke.

Stand No. 26.
Hoskison Mnfg. Co., Ltd., 20, Digbeth, Birmingham.

ON this stand is shown the new Hoskison lightweight motorcycle, fitted with the Union two-stroke engine, of a



The Hoskison two-stroke, a newcomer equipped with a Union engine and Burman gear.

cubic capacity of 293 c.c. The price of this model is in the neighbourhood of 65 guineas, and the manufacturers have spared nothing to make the machine as nearly perfect as it is possible for a lightweight to be. A Burman two-speed gearbox, with kick-starter and handlebar-controlled clutch is employed, transmission being by chain-cum-belt; 26 in. by 2¼ in. Kempshall non-skid tyres, B. and B. carburetter, and Runbaken magneto are standard, whilst the forks are Saxons, with the additional luxury of Terry's spring links. The mudguards are 7 ins. wide, with flap splashers both back and front. A chain case with a step boss covering the clutch is also fitted.

The tank holds 1¾ gallons petrol, and over a quart of oil, and is finished in French grey, lined black and gold. T.T. or upturned handlebars are optional, and the whole machine presents an extremely smart appearance.

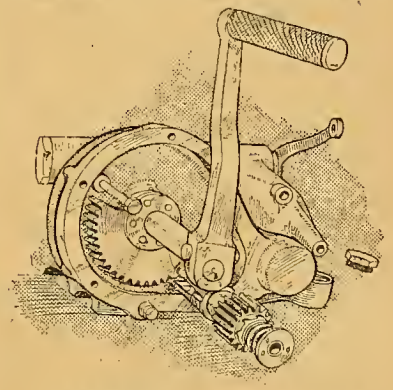
Stand No. 85.
Humber, Ltd., Coventry.

HUMBER'S are concentrating their efforts on one machine for 1920. This is an air-cooled horizontally-opposed twin equally suitable as a passenger machine or as a solo mount, rated at 4½ h.p., has undergone several modifications for 1920, the principal of which is an increase in the cylinder capacity to 600 c.c., the bore and stroke now being 75 by 68 mm. In order to increase the flow of oil to the big-ends the cranks now have dippers attached, and the tappets, which are, of course, adjustable, have stuffing boxes of a neat design.

Other features of the engine are split and white-metalled big-ends to the con-rods, and a special fitting of the valve pockets. These are held in position in pairs by a yoke and centre pin, which practice renders the removal of valve and seating for inspection a simple matter and finally overcomes that tiresome iniquity of air-cooled engines, the immovable valve cap.

A Claudel-Hobson carburetter is now fitted in place of the Longuemare of last season, and from all accounts suits the engine very well indeed, while the E.I.C. magneto is retained.

An important change has taken place in the gearbox. Last season's model had a high and low pinion constantly in mesh, and it was found that the turning effort of the larger of the low gear pinions revolving the smaller one idly on top gear was appreciable. Thus, the model exhibited has only one set of dogs for high gear, both the other ratios being engaged by the movement of a double pinion, hence, on top speed, only two pinions are idly in mesh. A kick-starter

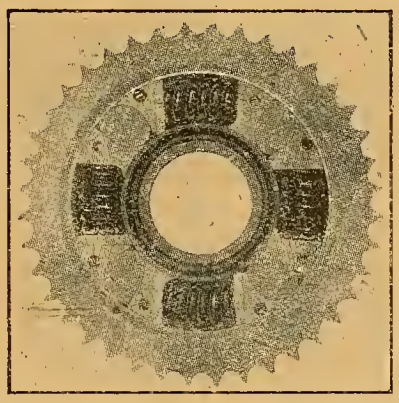


A kick-starter now replaces the handle on the 1920 Humber.

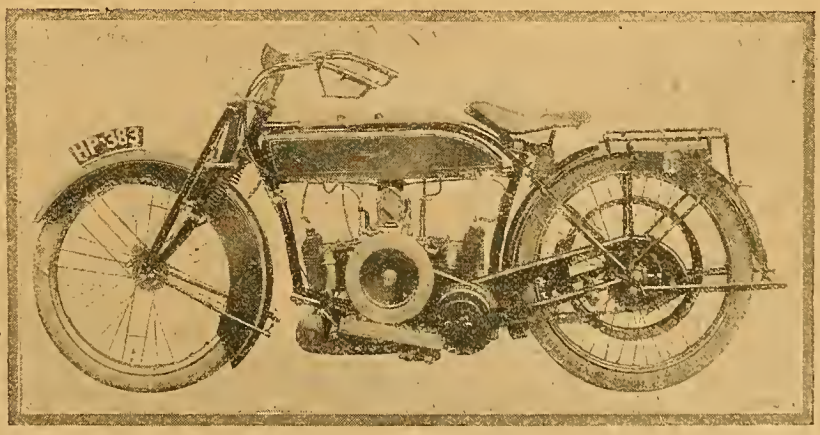
is now fitted in place of the handle, while the clutch plates formerly fixed are now floating, and the clutch is controlled from the handlebar instead of by the foot.

The capacity of the tank has been increased to 2¼ gallons, which makes possible the taking of a two-gallon can even though a little spirit remain from the previous filling.

The back brake shoe is now compensating, and grips the dummy belt drum inside, where it operates evenly for the entire length of the shoe during the whole of its life, wear taking place evenly. Other noteworthy points on the machine are the quickly detachable back wheel, the efficient chain covers, and the hinged back mudguard.

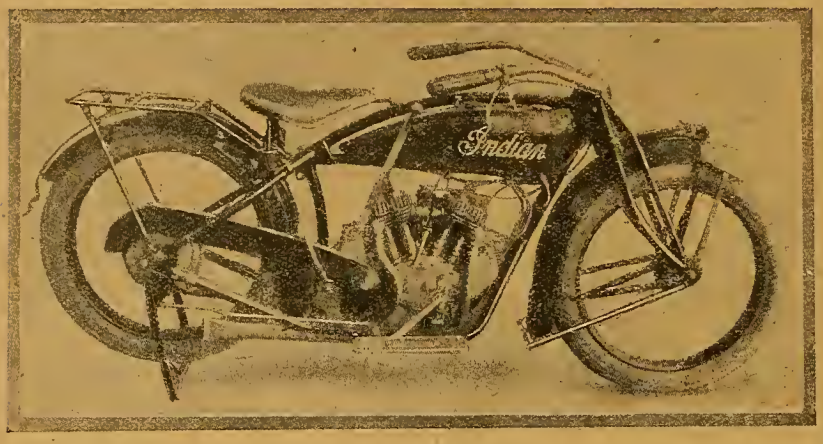


The shock absorber fitted to the Humber is composed of rubber buffers as well as springs.



The new 4½ h.p. Humber. Alterations to the gearbox have been made.

Indians Introduce a New Model—Ivy Individualities.



The new "Scout" model Indian—a welcome addition to the ranks of the small twins.

Stand No. 93.
Hendée Manufacturing Co., 366-368, Euston Road, London, N.W. 1.

THE bright and attractive colouring of Indian motorcycles comes as a welcome break in the somewhat monotonous black enamel of the bulk of the other exhibits. While only two models will be marketed next year—the well-known 7 h.p. Powerplus and the latest departure, the 4 h.p. small twin—many variations of the machines are staged. Overcrowding on the stand is overcome by suspending two of the machines in an attractive manner under the ornamental pillars of the facia.

Taking first the small 4 h.p. twin, known as the Scout model, this will be found staged firstly as a standard model, then with T.T. handlebars, and lastly in conjunction with a special light sidecar. It is a most attractive little mount, and we think that in its T.T. form it will prove an irresistible attraction to sporting riders of solo mounts. Its main features have been dealt with recently in these pages, so that there is no necessity to dwell on them at length, but we would advise those interested to pay special attention to the neatness and efficiency with which the drive is transmitted to the gearbox through gear wheels and also to note the extreme strength of the frame, which includes duplex down tubes.

The ultra-observant may notice that, as staged this model has only one brake fitted—an internal-expanding on the rear hub. The models supplied to the public will also be equipped with an external expanding band brake, Bowden operated from the handlebar.

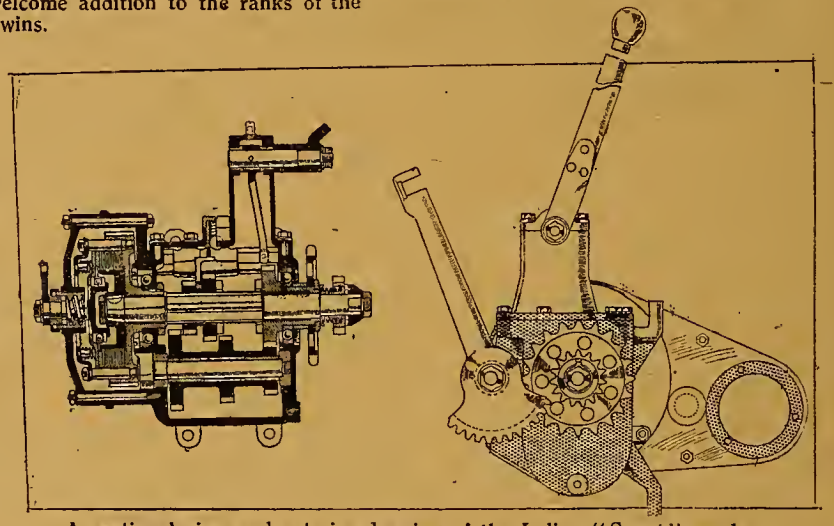
A similar range of 7 h.p. Powerplus machines are staged, and of these perhaps the sidecar combination will attract the most attention. The super elegance of the coming season's new design of sidecar body, incorporating, as it does, a bulbous back, will undoubtedly prove a centre of attraction.

Many sectional models of various parts of the Powerplus machine will be found on the stand, including one of the engine, the 7 h.p. gearbox, and another showing the composition of the clutch.

E20

"Isle of Man Sporting models." The frame is of special registered design, with dropped top rail, Duplex girder tubes being adopted instead of the usual round down tube. The engine is a two-stroke, rated at 2½ h.p., with bore and stroke of 60 mm. by 70 mm., giving a cubic capacity of 224 c.c. Albion and Sturmey-Archer two-speed gears are fitted on two models.

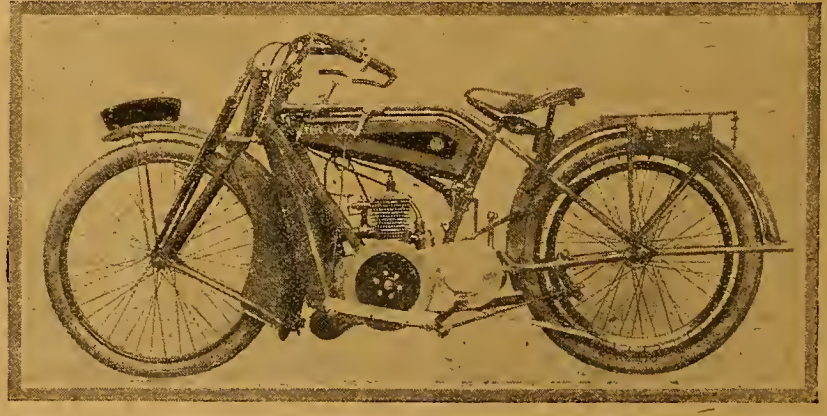
The tank is held on by three clips from the underneath rail instead of on the top, as hitherto, and has a capacity of 1¾ gallons of petrol and ½ gallon of oil on all models. The mudguards are wider, and are fitted with side valances for back and front guards. The tyres are 26 in. by 2¼ Dunlops, and the two sporting models are supplied with disc wheels. The "All-purpose" models have footboards and knee shields. The stand is a combination of the clip-up and spring-up types, a powerful spring lifting the stand the moment the machine is pushed forward, and bringing the rail into an ordinary clip at the tail of the back mudguard. It is thus held firmly and without rattle. The machines present a very smart appearance.



A sectional view and exterior drawing of the Indian "Scout" gearbox

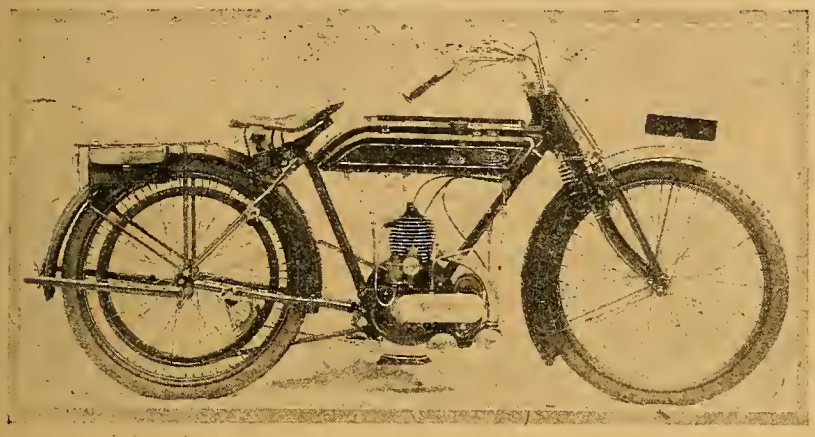
Stand No. 91.
S. A. Newman, Ltd., Lichfield Road, Aston Cross, Birmingham.

IVY motorcycles are shown this year in four models—single-speed and two-speed de luxe "All-Purpose models" and single-speed and two-speed de luxe



One of the many attractive features of the Ivy is the inclusion of leg guards.

Ixions—James continue their 3½ Twin, Big Single, 6 h.p. Twin, and Two-stroke Models.



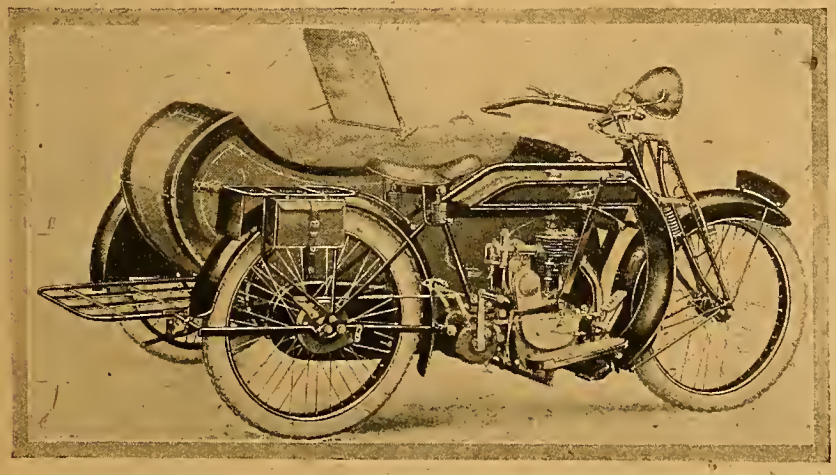
The single geared Ixion which has a Villiers engine.

Stand No. 22.

Ixion Motor Mnfg. Co., 35, Gt. Tindal Street, Ladywood, Birmingham.

THE well-known Ixion motorcycles are shown this year in four models. Model A, single gear; Model B, two-speed, with no clutch; Model B OIK2, two-speed, with kick-starter and clutch; Model D, two-speed, kick-starter and clutch, lady's model. As in the past, a 2½ h.p. Villiers engine is fitted to all types. The tyres are 26 in. by 2 in. Dunlops, the forks Druid girder type, and the saddle a Leatheries de luxe or X-L-All at option. Aluminium footboards are standard on Models BMK2 and D, and can be fitted for a small extra price on the other types.

A lady's model is particularly neat. The shields and dressguards are substantial and efficient, and the machine can be ridden without any alteration to the clothing. Above all it is particularly cleanly, light and easy to start. It should have a large market amongst ladies, for no matter what may be said to the contrary, there is no doubt that the majority of the fair sex dislike special motor-cycling clothes.



The James big single sidecar outfit has many attractive features. A 6 h.p. twin is also made.

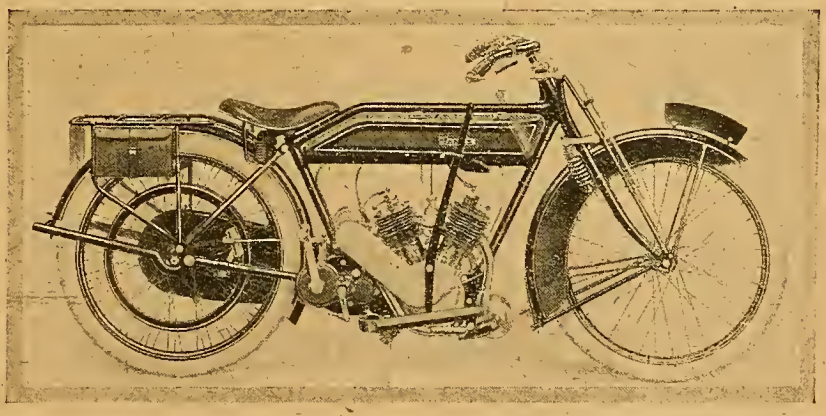
Stand No. 71.

James Cycle Co., Ltd., Greet, Birmingham.

A REPRESENTATIVE display of the four James models is on view, from the little two-stroke lightweight to the 6 h.p. combination. The two-stroke is of the three-port type, and has chain drive by two chains to a countershaft, the gears being obtained by a selective dog clutch. The wheels are now for 26 in. tyres, and with larger tank, and wide flat handlebars the small machine is much improved.

The 3½ h.p. twin is a particularly attractive solo mount. Its engine is distinctive by reason of its staggered radiating fins. All-chain drive is adopted, with handlebar-control clutch and three-speed gearbox. The sidecar models are the big single 4½ h.p. and the 6 h.p. twin. The big single has performed so well in reliability trials that it is too well known to need description. All-chain drive, totally enclosed, is a feature, and the James three-speed gearbox, embodying foot-controlled clutch, kick-starter, and three-speed gear, is particularly strong and neat. A comfortable riding position with wide handlebars and large footboards make a long tour an easy task, particularly as 28 in. wheels are now standardized on this model.

The James Canoelet sidecar is comfortable and strong, and finished in a rich brown to match the tank, the whole combination makes an irresistible appeal to the eye. The 6 h.p. twin is a powerful mount on similar lines, 28 in. wheels being fitted, and the gain in comfort by reason of the larger wheels is very great. The sidecar lugs are brazed on to the frame of the machine, and five-point attachment is provided. The Lucas Magdyno may be had on this model, and is fitted in place of the ordinary magneto, high up behind the rear cylinder.

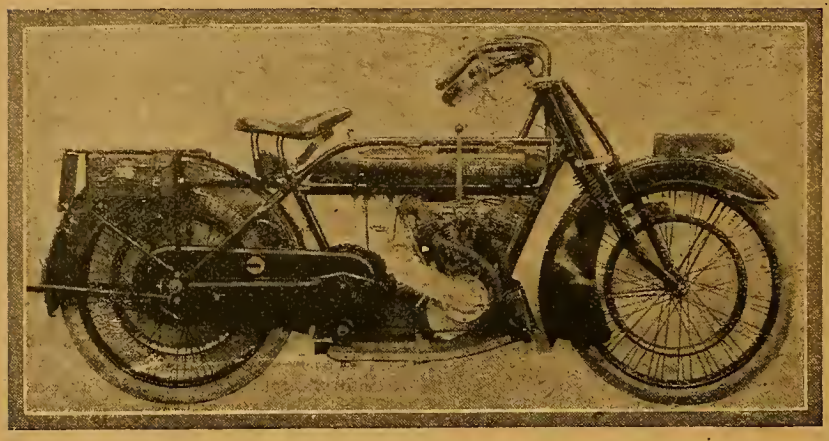


The James is one of the few remaining 3½ h.p. twin solo machines.

The rear brake on this model, as well as on the 4½ h.p. machine, is of the internal-expanding type. The mudguards are of large domed section, and when fitted with leg shields, which may be had as an extra, the outfit forms an ideal all-weather combination.

As an outfit de luxe this James combination is hard to beat. For the change-speed control a long lever is mounted on the right-hand side of the machine, and is very conveniently arranged.

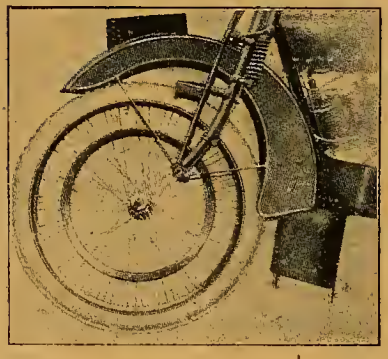
The Popular Levis Lightweight—The Lea-Francis Programme.



One of the new M.A.G.-engined Lea-Francis machines.

Stand No. 50.
Lea and Francis, Ltd., Lower Ford Street, Coventry.

FOUR Lea-Francis machines are exhibited, two with J.A.P. and two with M.A.G. engines. Owing to the uncertain conditions of present-day supplies the option has to rest with the makers, although they do their best to supply customers with engines of their choice. These machines follow very closely the models of previous seasons. The carburetter is an A.M.A.C. single-lever instrument, and a chain-driven Thomson-Bennett magneto is fitted between the gearbox and rear cylinder. This position gives ample weather protection with accessibility. The transmission is chain with a cush drive. The chains are readily accessible by removing the top half of chain cases. These latter are dust and oil tight.



Detachable wheels are standard on the new Lea-Francis machines—

The Lea-Francis two-speed gear is of the sliding-dog constant-mesh type, with ball bearings throughout. The clutch is of the multiple-disc pattern and has excellent provision for lubrication. The gear ratios are, so far as possible, adjusted to the district in which the machine is to be used; 26 in. Palmer tyres are fitted, and both wheels are instantly detachable, the front without disturbance to the brake and the rear without touching the chain cases. Both brakes operate on a dummy belt drum internally. The rear hub runs on double row self-aligning ball bearings. The tank is enamelled black with a red panel, and nicely sets off the rest of the machine; its capacity is 1½ gallon of spirit and 3 pints of oil. Lubrication is effected by a sight drip feed, combined with a hand pump, while the chains are automatically oiled from the gearbox supply.

The footboards are curved and of good length. They have a shield forward to intercept possible stray splashes that get past the front guard. Both wheels are provided with stands, the front having an underscreen incorporated in its design. The frame itself is of special design, one very creditable feature of which is the absence of cranked lugs in the chain stays. Another feature is the long steering head relieving the ball races of much strain. In designing this machine the makers were determined to build to an ideal rather than to a price.

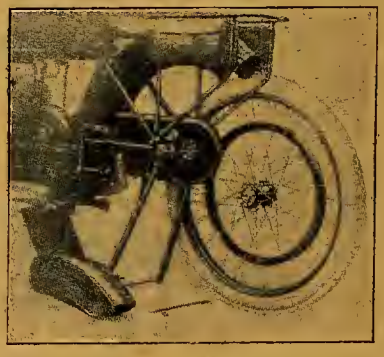
From the accompanying illustration it will be seen that the engine is placed well forward in the frame. This tends towards better weight distribution and consequent greater stability in grease. The fact that the gearbox is in a slightly raised position not only permits of a slightly longer length of driving chain being used, but gives the machine a decidedly neat and compact appearance.

Stand No. 80.
Butterfields, Ltd., Levis Motor Works, Station Road, Stechford, Birmingham.

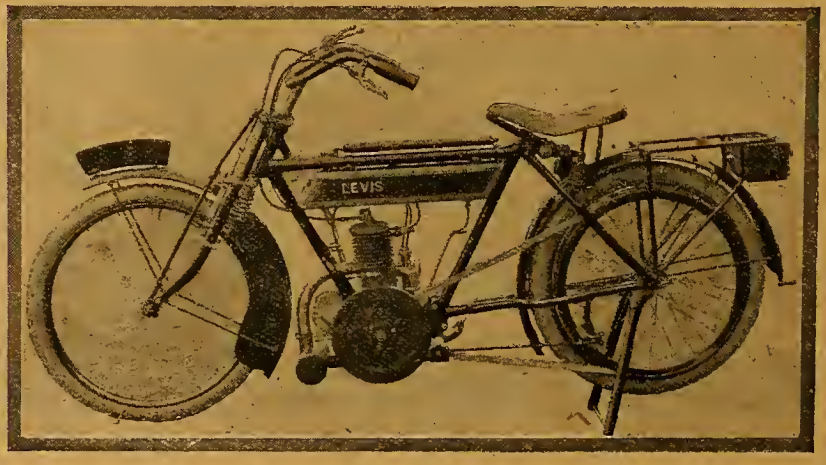
THE reputation of the Levis as a touring machine capable of covering the severest country and performing miracles of hill-climbing is well known, and three examples of the new Popular model are shown on this stand. The model differs but little from previous Levis machines, but has been improved in detail. Levis riders will at once notice the new colour scheme, for a grey tank with black panels and top is now fitted.

The 2¼ h.p. engine with bore and stroke of 62 mm. by 70 mm. is fitted, giving a cubic capacity of 211 c.c. The piston has a deflector top and two piston rings are fitted, being pegged to prevent rotation. The crankshaft is carefully balanced and ground to size. The direct belt drive is retained for this simple machine, which can truly claim to be a lightweight. The wheels are for 24-in. tyres.

A new model known as the Baby is also on view, but it will not be put into production before midsummer. The same engine is employed, but is re-designed with a roller bearing to the big-end of the connecting rod. On this model a two-speed Enfield gear is standard, with chain-cum-belt drive.

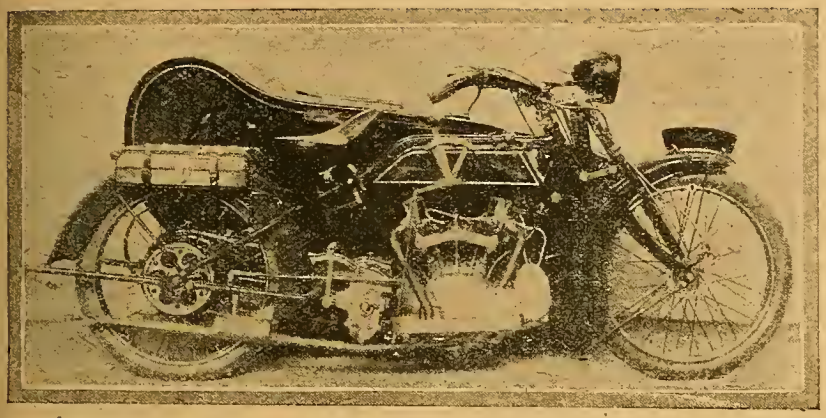


—and the rearguard is made in two pieces which can be easily removed.



The Baby Levis, which is noted for its hill-climbing powers.

The Martinsyde Makes Its Debut.



Side view of the Martinsyde combination.

Stand No. 43.
Martinsyde, Ltd., Maybury Hill, Woking.

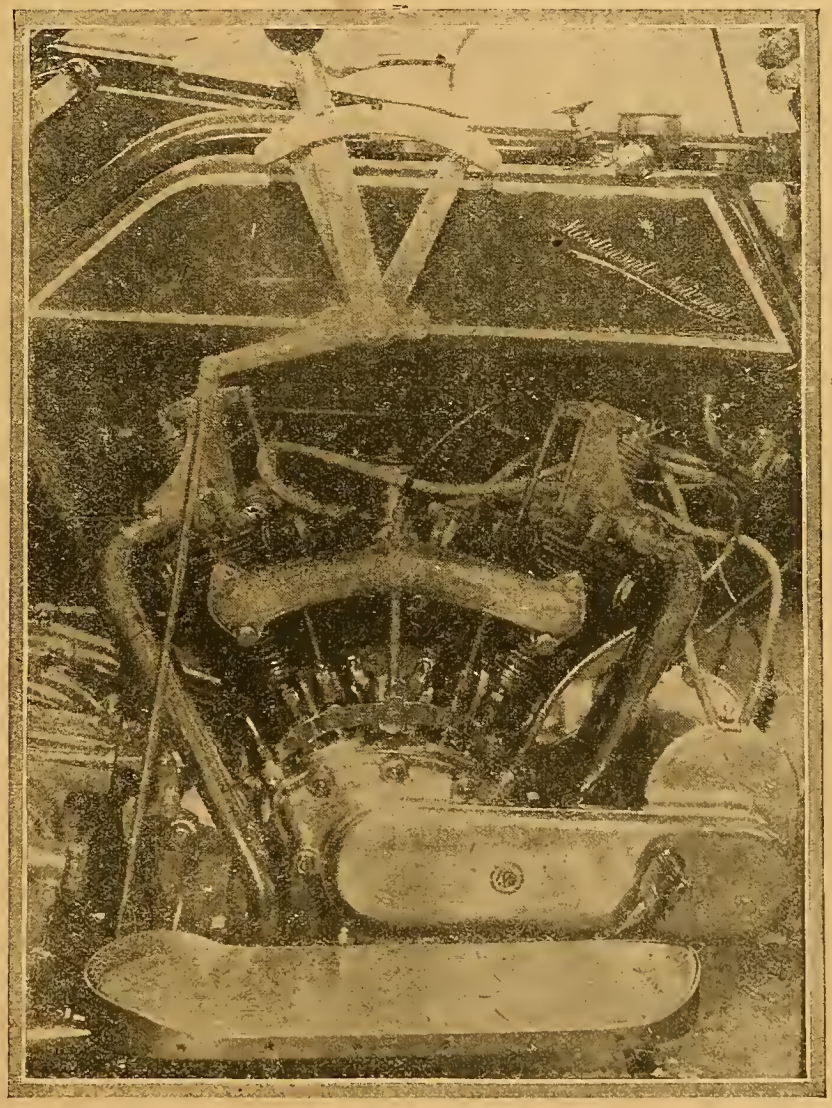
THE machine to be seen on this stand is a Martinsyde-Newman, which is an entirely newcomer to the motorcycling world, but nevertheless should make a strong appeal by reason of its being produced by a well-known aviation firm to the well-tested design of a noted motorcyclist.

To outward appearance it presents a conventional appearance, but closer examination will reveal that a feature of its 6 h.p. V twin engine is the method of placing the exhaust valves in the cylinder heads, over the inlet valves. The cylinders are set at an angle of 50 degrees, and have a bore and stroke of 70 mm. by 88 mm., giving a capacity of 680 c.c. Advantages claimed for the overhead exhaust valves are that cooling is improved and that the cylinder is completely scavenged of burnt gas on the exhaust stroke, ensuring even cylinder expansion. Roller bearings are fitted to the big-ends, and the mainshafts run on ball bearings of ample size. Foolproof automatic lubrication is employed, consisting of a sump in the timing case and a specially-designed flywheel splash action. The cast aluminium induction pipe has no angularities, so permitting of an easy passage of gas to the cylinders Snugly placed between the latter, and so continually in a warmed position, is situated the single-lever A.M.A.C. carburetter. The magneto is located in front of the engine, low down, and is very completely encased in an aluminium box. The two exhaust pipes join up just below the timing case, and the gas is conducted to an expansion box supported below the chainstay, from which a further pipe ejects it well to the rear of the machine.

Transmission is all-chain; with a three speed gearbox of the A.J.S. pattern fitted at the countershaft. The cork in set clutch is controlled from the handle bar, and a kick-starter is provided. Both chains are enclosed in oil-tight cases.

The tank is of square design, holding two gallons of petrol and half a gallon of oil. The filler caps are of large size. Brampton Biflex pattern forks are fitted, manufactured under licence, and 650 mm. by 65 mm. wheels. The foot brake is of the contracting band type, placed on the rear hub. Mudguards of good size, with side valances, ensure protection to the machine and rider. An electrical equipment is provided, consisting of Lucas head and tail lamps and accumulator, but no dynamo. Extremely good accommodation is made for carrying tools and spares by two leather bags, which run the whole length of the carrier, and have two straps in addition to the usual patent fastener. The whole machine is enamelled a pleasing shade of dark blue, and the tank is lined in gold. The engine unit is buffed and plated wherever possible, and the crankcase casting is devoid of projections to harbour dirt and mud.

It is intended that the Martinsyde sidecar shall form part of the outfit, and this comprises a handsome bulbous-back body, finished in royal blue, suspended on a well-designed chassis.

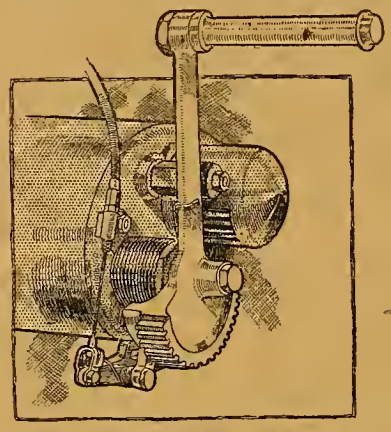


The valve side of the Martinsyde engine. Note the overhead valves and novel exhaust pipes. The engine has automatic lubrication and was designed by Mr. Newman of "Ivy" fame.

A Sumptuous Passenger Machine—Two Popular Two-strokes.

Stand No. 48.
Collier, H., and Sons, 44, Plumstead Road, Plumstead, S.E. 18.

ON this stand are shown several Matchless sidecar combinations, the latest edition of which is a striking example of the high level of excellence which the modern outfit has attained. The 8 h.p. J.A.P. engine drives through a silent chain to the three-speed gearbox,

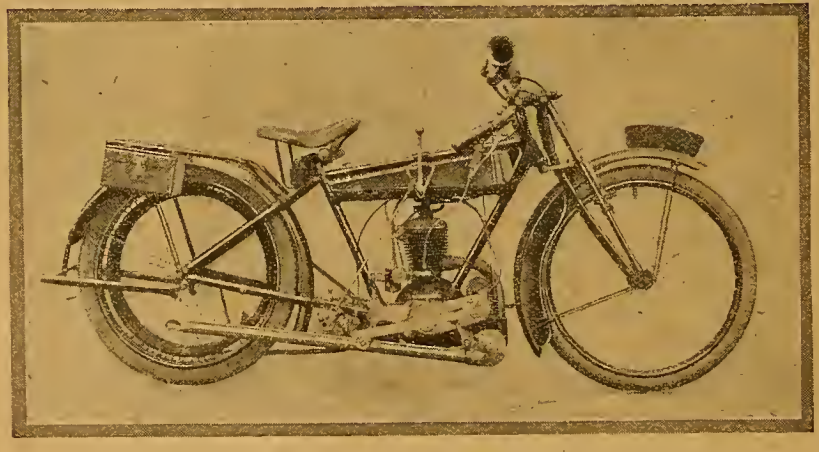


The Matchless kick-starter which auto matically raises and drops the exhaust valve by means of a cam.

which is of cylindrical shape, secured to the frame by means of two substantial metal straps. Final drive is through a Renold $\frac{5}{8}$ in. by $\frac{3}{8}$ in. roller chain. Both chains are enclosed in separate easily-detachable and oil-tight cases. Oil is supplied to the crankcase through a Best and Lloyd semi-automatic pump, lubrication to the big-end and main bearings being under pressure on the well-known J.A.P. system of utilizing crankcase compression for the purpose.

The unique feature of the machine is the rear suspension, the back and sidecar wheels being linked together by means of a tubular truss, carried on compression springs, which arrangement prevents leaning when rounding corners. This design provides extraordinary resilience, and should on no account be missed. The tyres are 28 ins. by 3 ins., mounted on detachable and interchangeable wheels. Another item of interest is the method whereby the exhaust valves are lifted by the free movement of the kick-starter crank, the valves being allowed to return to their seats at the moment when the greatest purchase is being obtained. This does away with the need for the usual valve lifter lever, and as the ignition lever is situated on the left-hand side of the tank, a remarkably clean handlebar is the result, the only levers in that position being those actuating the front brake, gas, and air.

The sidecar is a most roomy and luxurious affair, the body being mounted on laminated springs at the front and coil springs at the rear, which, in conjunction with the special springing system inculating both rear and sidecar wheels, provides extraordinary comfort. The body is built up of sheet metal panels, and has a large tool compartment under the seat, while a large locker in the back accommodates the spare can of petrol, rugs, etc.

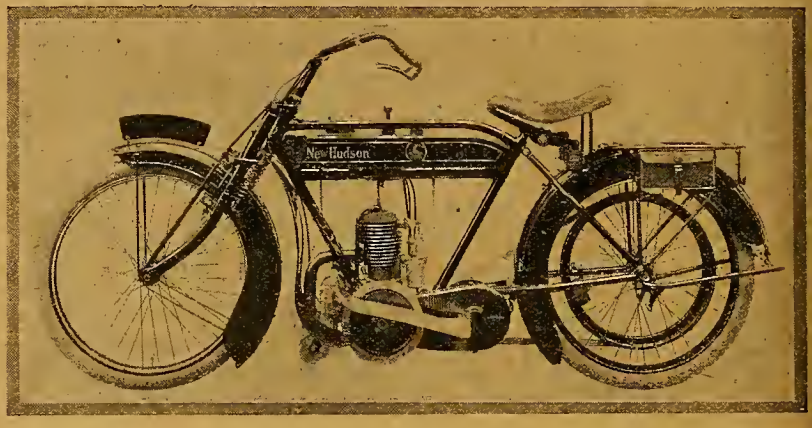


The Metro-Tyler two-stroke is a soundly designed and powerful lightweight. It hauls a light sidecar quite satisfactorily.

Stand No. 65.
Tyler Apparatus Co., Ltd., Banister Road, Kilburn Lane, North Kensington, W. 10.

THREE models of the Metro-Tyler two-stroke are to be seen at this stand, the single-speed all-belt drive model, the two-speed chain-cum-belt, and the new 1920 chain-cum-belt model. All three are equipped with a $2\frac{1}{2}$ h.p. two-stroke engine of 70 mm. by 70 mm. bore and stroke respectively.

The new model embodies a number of unique features which include a welded frame. The engine is of the three-port variety having an inspection trap over the transfer passage. The whole power unit, two-speed gearbox, and magneto comprise a complete unit and are mounted between steel housing plates. These in position form part of the main frame. The gearbox may be moved along slotted holes in the plates for chain adjustment, and the magneto, which is secured to an aluminium bracket between engine and gearbox, may be moved in a similar way. The machine is equipped with Brampton forks, X-L-All saddle, 26 in. by $2\frac{1}{4}$ in. tyres, and a particularly neat toolbox between the number plate and rear mudguard. The price will be £70.



The New Hudson two-stroke, 24 in. wheels are standard, which result in a very low riding position.

Stand No. 74.
New Hudson Cycle Co., Ltd., Icknield Street, Birmingham.

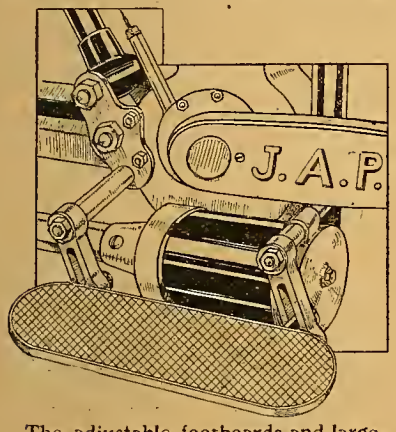
THE New Hudson policy for 1920 consists of the manufacturing of two-stroke motorcycles, both models of which are shown on this stand. The power unit has several interesting features, which were described fully in a recent issue of *Motor Cycling*. Transmission is by chain in an oil-bath case to the countershaft two-speed gearbox, and thence by belt to the back wheel. The whole machine is of very smart appearance, and an especially low riding position is obtained by the use of 24 in. wheels. Footboards and knee-shields are standard on the touring model, whilst the sporting model is fitted with footrests and T.T. bars.

New Imperial Innovations—The Norton Special Speed Models.

Stand No. 60.
New Imperial Cycles, Ltd., Princip Street, Birmingham.

ON this stand are shown three models of the New Imperial motorcycles that are to be standardized for 1920. These are as follow: — Model 1, 2¾ h.p. two-speed; Model 2, 2¾ h.p. two-speed, clutch, and kick-starter; and an 8 h.p. combination.

The two lightweight machines are fitted with J.A.P. four-stroke engines,



The adjustable footboards and large silencer now fitted to the New Imperial.

with bore and stroke of 70 mm. by 76 mm., B. and B. carburetter, E.I.C. magneto, 26 by 2¼ Dunlop tyres, and pan-seat saddle are used. The tank has been enlarged, and now has a capacity of 1½ gallons for petrol.

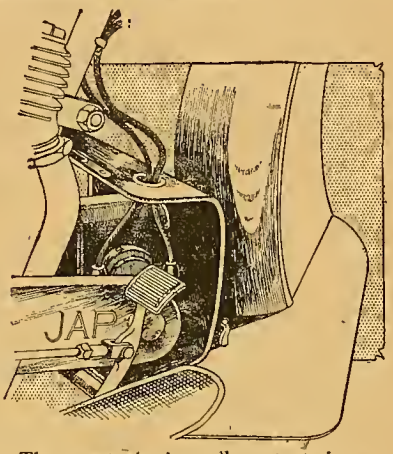
The combination has an 8 h.p. twin J.A.P. engine, three-speed countershaft gearbox, and all-chain drive; 28 in. by 3 in. Dunlop tyres are fitted, and the ground clearance of the engine is 6 ins. The chassis of the sidecar is strongly built, and the body is well upholstered.

The prices of New Imperial motorcycles are as follow:—Model 1. 58 guineas; Model 2, 65 guineas; and the 8 h.p. combination 138 guineas.

Stand No. 115.
Norton Motors, Ltd., Bracebridge Street, Birmingham.

A FULL range of Norton models are shown, with either all-chain or all-belt drive. The "Big Four" Norton is rapidly becoming a very popular sidecar machine, but is also a taking solo mount. It has a bore and stroke of 82 mm. by 120 mm., giving a capacity of 633 c.c. Heavy Druid forks and 650 mm. by 65 mm. heavy Dunlop tyres are standard. Transmission is effected by chains and a three-speed Sturmey-Archer gearbox is fitted, containing kick starter and hand-controlled clutch. A large tank is employed, with a capacity of two gallons for petrol and three pints for oil. Lubrication is by semi-automatic drip feed. The makers claim that it is capable of 50 m.p.h. with a loaded sidecar, and undoubtedly it makes a very handsome and sporting combination.

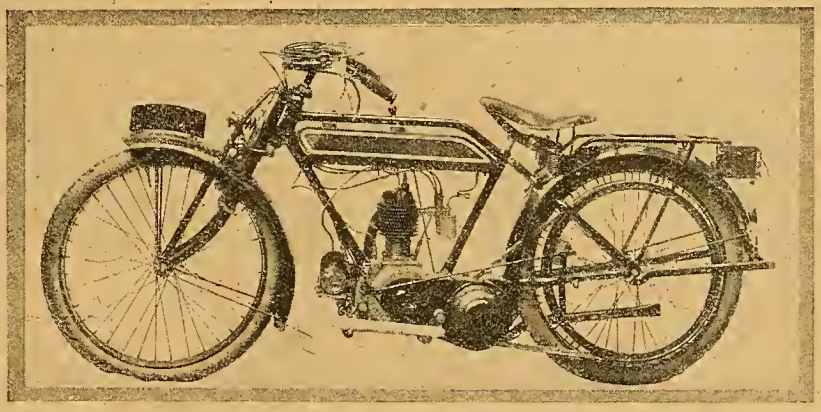
A 3½ h.p. Sports Norton is also shown, the bore and stroke being 79 mm. by 100 mm. = 490 c.c. It has all-chain drive, with three-speed Sturmey gearbox. The gears fitted are 4½, 7¾, and 13¼ to 1, and the machine is claimed to be the fastest



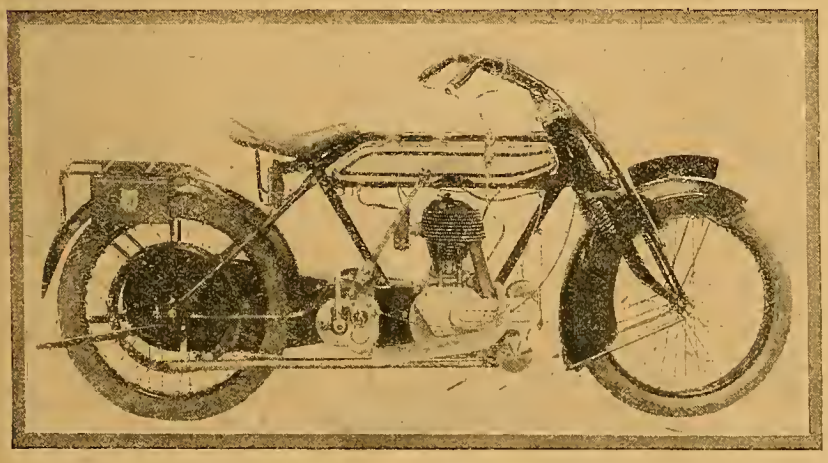
The magneto is well protected on the 8 h.p. machine.

touring model made. The tank, tyres, etc., are the same as on the utility model.

Three machines which always shine at hill-climbs and speed events are the Speed Norton, the Brooklands Road Special, and the Brooklands Special, exam



The 2¾ h.p. J.A.P.-engined New Imperial lightweight which is fitted with Saxon forks.



The 4 h.p. long-stroke Norton is an ideal all-purpose machine.

ples of which are the centre of a knot of speed enthusiasts. The 3½ h.p. machine is fitted with direct belt drive from an adjustable pulley, and spring forks, 26 in. by 2¼ in. Dunlop tyres, footrests, B. and B. carburetter, dropped handlebars, long exhaust pipe with detachable silencer are standard. Lubrication is by hand pump. A low centre of gravity and special attention to weight distribution have evolved a machine which is very steady at high speeds. An epicyclic two-speed gear may be had on the Speed Norton if desired. Adjustable tappets are now fitted.

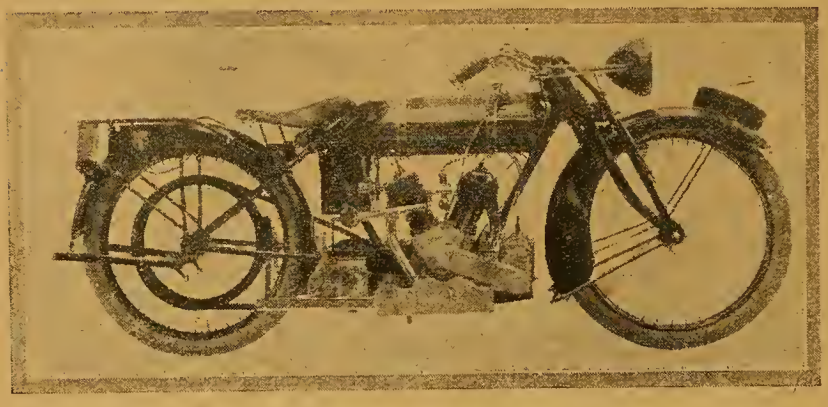
Sidecars are catered for in the Utility combination with Norton de luxe sidecar. The rear C springs are three-leaf and shackleless, with quarter-elliptic toe springs. The deep-green upholstery is spring padded and the finish is green with black band. A model with a more commodious body extension forming a child's dickey seat and also a sports combination are shown.

The New N.U.T.—The Cheapest Motorcycle (O.K.)—Omega Models.

Stand No. 116.
Newcastle-upon-Tyne Motor Co., Ltd., St. Thomas Street, Newcastle-upon-Tyne.

THE N.U.T. machine has been entirely redesigned, and is now presented in one model only—a medium-weight twin. The engine is a 3½ h.p. 50-degree V twin N.U.T., with cylinders of 64.5 mm. bore and 76 mm. stroke. The mainshaft runs on ball bearings on the driving side, and on a phosphor-bronze bush on the timing side. Side-by-side valves with adjustable tappets are fitted, and lubrication is by special automatic pressure feed in the crankcase. Ignition is by Lucas Magdyno, which also provides current for the electric lights.

The gearbox is a Sturmey-Archer three-speed, with kick-starter and hand-controlled clutch, and chain-cum-belt transmission is employed. The gear ratios are 4, 6½, and 10¾ to 1.



The N.U.T. has been a long time on the way, but now it has arrived it fulfils expectations.

The frame is of very low build, and the tank oval in shape, is help in position by two nickel-plated straps. The top of the tank is recessed, so that the top tube does not project above the tank. A Druid spring fork is fitted; the foot brake is a Ferodo-lined pad which works in the V of the belt rim. Even pressure over the whole surface of the shoe is ensured by a compensating device.

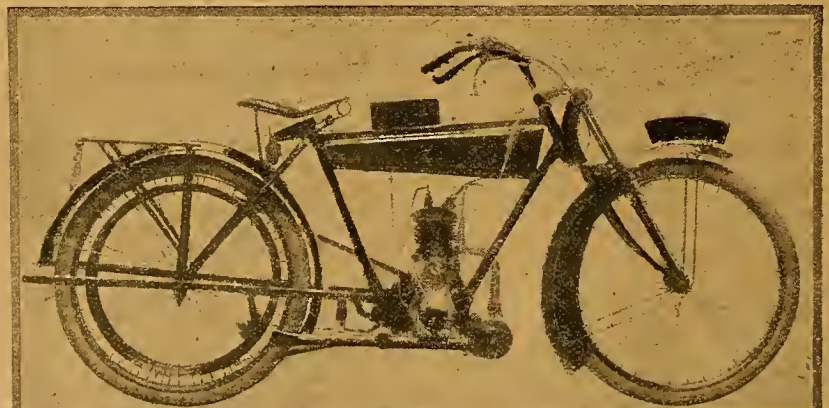
Every machine is equipped with the Lucas lighting outfit. The accumulator is fixed in a metal box on the seat tube, and is kept charged by the Magdyno.

A 5 in. headlamp is fitted, the clips for which are brazed to the handlebar, and the switch is placed at the rear end of the tank.

Mudguarding is very efficient, and the carrier strong and well-designed. Palmer cord 26 in. by 2½ in. tyres are fitted as standard, and a Brooks' saddle and pannier bags complete the equipment.

Stand No. 86.
Humphries and Dawes, Ltd., Hall Green Works, Birmingham.

MESSRS. HUMPHRIES & DAWES are this year concentrating on two models of lightweight motorcycles, both of which are exhibited at Olympia. One is a 2¾ h.p. single-geared two-stroke model, and the other a 2¾ h.p. horizontally-opposed four-stroke twin. The machines are known as the O.K.-Union, Mark VIII, and the O.K. Junior, respectively.



The cheapest motorcycle at Olympia—the O.K.-Union, selling at 38 gns.

The O.K.-Union is a remarkably cheap motorcycle, selling at the low price of 38 guineas. It is fitted with a Union engine, with a cubic capacity of 293 c.c.; 26 in. by 2 in. Hutchinson tyres, and Dunlop belt, are supplied, whilst the spring fork is the patent O.K., with the flat laminated circular spring. The low price is attained by the mass production system which is employed.

The O.K. Junior has a horizontally-opposed engine, with a cubic capacity of 347 c.c. The fork is of similar design to the two-stroke type, and the wheels are 26 ins. by 2¼ ins., and are easily detachable. The brakes are internal-expanding, as used in car practice. Foot boards with engine shield in one are fitted, and the mudguards are domed, well-valanced, and of ample size. A two-speed gear with gate change, clutch, and kick-starter is provided.

Stand No. 46.
Green, W. J., Ltd., Hill Street, Coventry.

THE Omega machines for next season have many small improvements. The principal one is the placing of the engine forward a little further for the purpose of stability on grease. Mudguards are now very much wider, that on the front wheel being 5 ins. from edge to edge. The chain is now adjusted by sliding the gearbox along a special bottom bracket instead of the front tubes. Footrests are of aluminium in place of rubber. The head lug has been strengthened considerably.

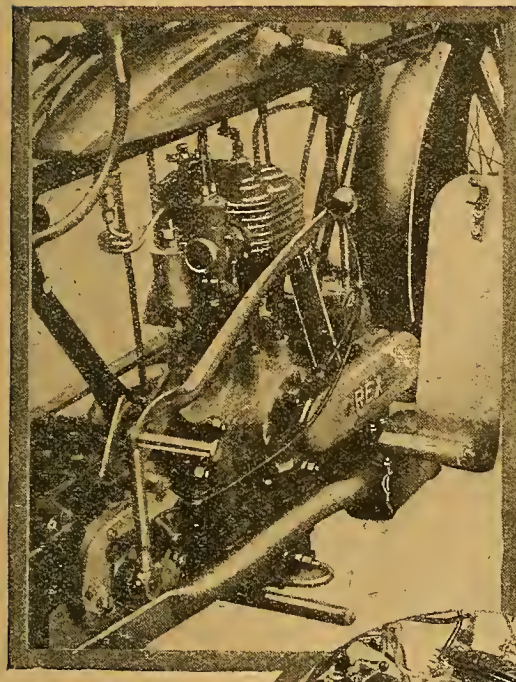
There are three standard models. Model A has a two-speed gearbox, but no clutch, and touring handlebars. Model B is similar, but has T.T. bars, nd model C, which is similar to mode A, but has the addition of a clutch and kick starter.

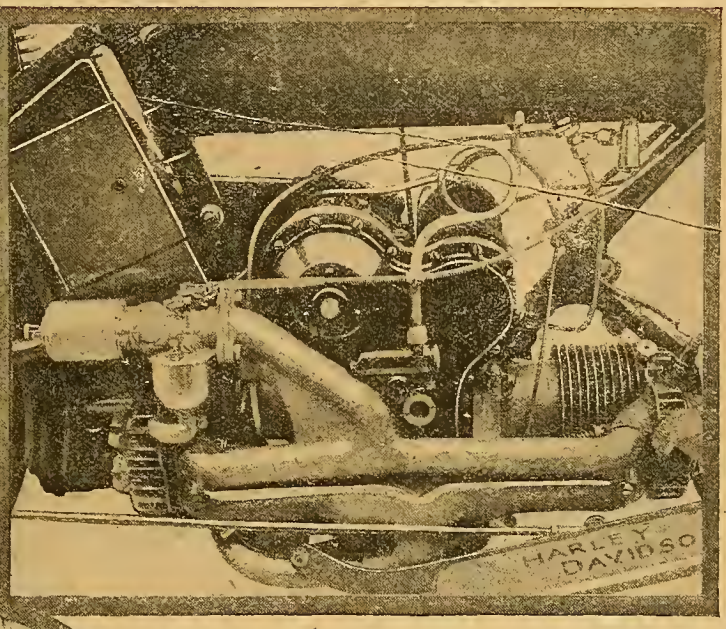
The engine is a 2½ h.p. J.A.P. (70 mm. by 76 mm., 292 c.c.), with internal exhaust lifter and adjustable tappets. A B. and B. lightweight carburetter is fitted, and a C.A.V. or M.L. magneto. The gearbox is a Burman two-speed, with pinions constantly in mesh, high and low gears being engaged by dogs of good size conducted by a lever in a gate on the right-hand side of the tank. The forks are Brampton Biflex, and the tank is finished maroon and black, having a capacity of 1¼ gallon of fuel and 1 quart of oil. Its rear panels are sunk slightly to accommodate the rider's knees. Lubrication is by a hand pump inside the tank.

Transmission is by ½-in. by 3-16-in. roller chain to the countershaft and ¾-in. Dunlop belt over larger diameter countershaft pulley to the back wheel. Chain and belt pulley are well protected by an aluminium guard. The wheels are all black, and one model is shown with discs which may be had for 50s. extra; 26-in. by 2¼-in. Dunlop studded tyres are fitted. The handlebars may be either nickel-plated or black finish at purchaser's option. The front brake is the ordinary rim pattern and the rear one a heel-operated brake gripping the outside of belt drum below the stays.

Prices are as follow:—Models A and B, 58 guineas; Model C, 68 guineas.

SOME OF THE LATEST POWER UNITS.

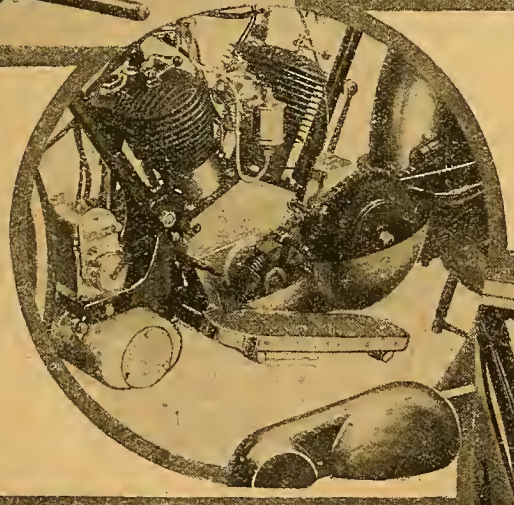


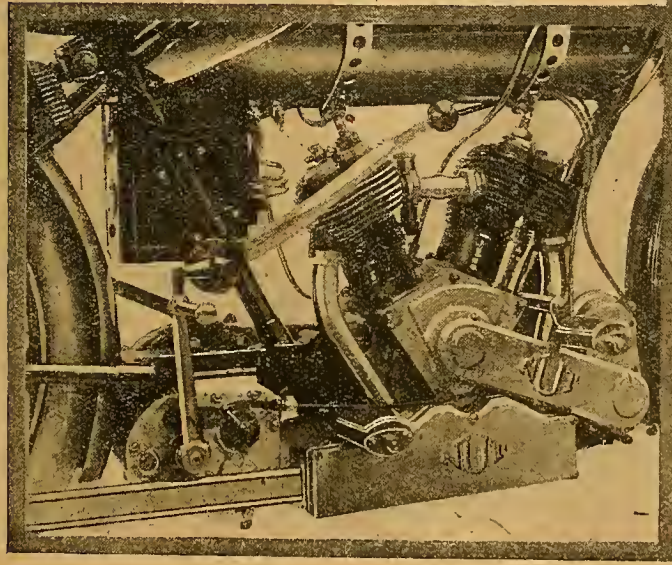


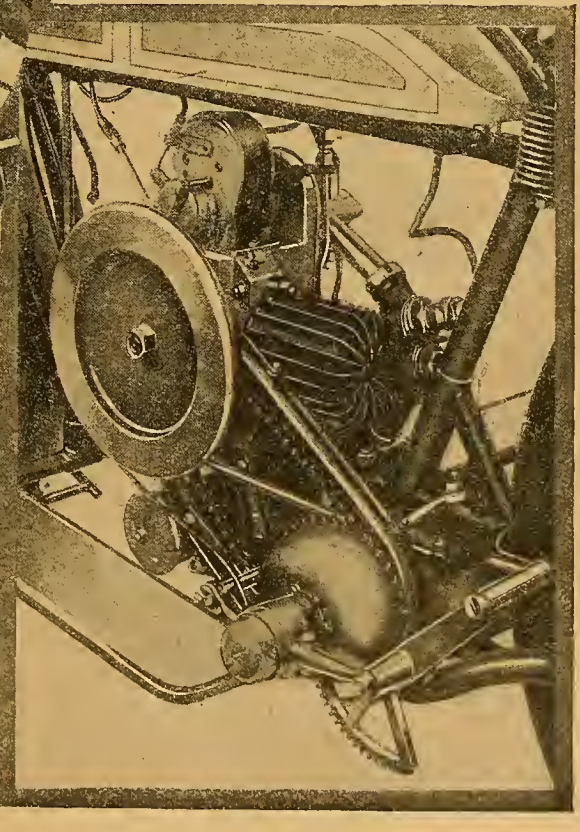
Centre: The twin B.S.A. with case removed, showing cush drive.

Bottom: The N.U.T., showing unusual silencer, and the 2¾ h.p. kick starter model Douglas.

Top: The Rex "sidecar single," and the h.o. twin Harley-Davidson.







The Immaculate P. and M.—The Spring-wheel Paragon.

Stand No. 63.

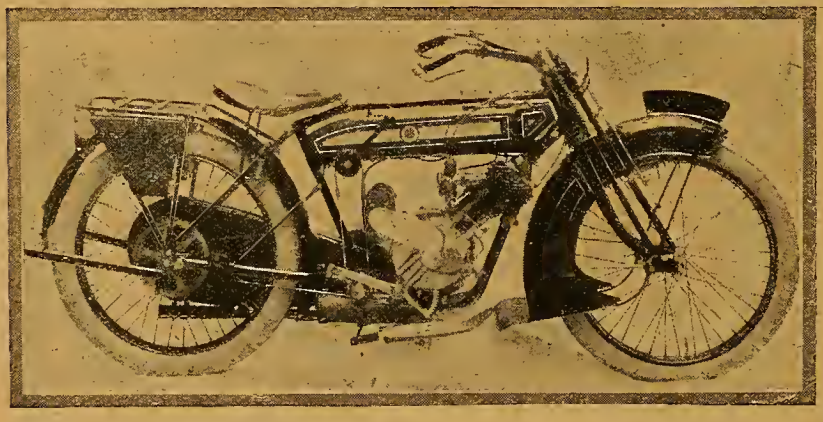
Phelon and Moore, Ltd., 4 Berners Street, London, W. 1.

THIS exhibit is sure to attract a good deal of attention if for no other reason than that of the declared policy of the concern in the matter of price, which is that all machines delivered prior to March 31st next will be sold at £95. This is a point that could be copied with advantage by other manufacturers, as it spares riders waiting for delivery the anguish of seeing prices advance perhaps a few days before the machine arrives.

In general outline the P. and M. remains more or less unchanged, although there are a number of valuable detail refinements which indicate that the manufacturers are alive to the necessity of keeping abreast with the times. The first point which attracts attention is undoubtedly the new design of cylinder, which has the radiating fins placed parallel with the ground, while internally the valve ports have been perfectly streamlined and the valves themselves are larger. This has resulted in a considerable increase of power.

Another departure is the fitting of a mechanical lubrication pump which runs at one-fortieth of engine speed, and is driven by a worm from the back of the exhaust cam wheel. The plunger delivers oil alternately to the left-hand main engine shaft (thence to the big-end), and to the rear of the cylinder. The provision of independent lubrication to the piston has resulted in the complete eliminaton of piston slap. The bore and stroke are the same as before, viz., 84.5 mm. by 88.9 mm., giving a capacity of 498 c.c.

The P. and M. toolbag has room for a spare tube and can be securely fastened.



The P. and M. has mechanical lubrication and a re-designed cylinder.

The new kick-starter is of the quadrant and pinion type, and the crank, being exceptionally long and carried well back, renders it an easy matter to start the engine, the half compression device which has so long been a feature of the Phelon and Moore assisting this materially.

The spring fork has been slightly altered, the new design incorporating two external tension springs in place of the single encased compression spring hitherto fitted. The action of the fork has been greatly improved by giving it increased movement, and it is claimed to be entirely proof against sidecar drag.

The rear external contracting brake is operated by a pedal and lever, which are interconnected, the latter working in a ratchet quadrant which holds it in any desired position. This is a very valuable feature, as it enables the machine to be left standing on a hill without any danger of running away.

Two large tool bags, which are fitted to the carrier, are secured by means of spring steel strips, a distinct improvement on the orthodox strap or lock fastenings, the latter in particular being prone to give trouble. The machine has an all-weather finish, even the handlebars being celluloid covered. The tank is enamelled in royal blue with light blue lines and grey panels, the royal blue harmonizing with the finish adopted by the makers for their sidecar bodies.

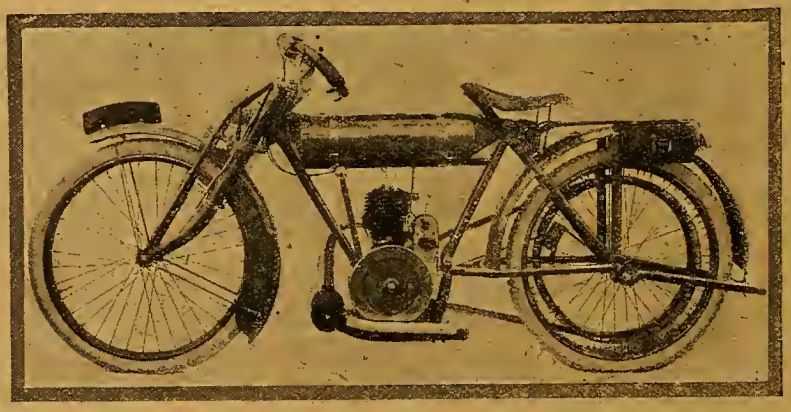
Stand No. 70.

Paragon Motor Manufacturing Co., Manningtree, Essex.

THE Paragon motorcycle takes the form of a 3 h.p. single-cylinder two-stroke, the engine forming one unit with the gearbox, mounted in a neatly-sprung frame.

The cylinder is of 76 mm. bore and with stroke of 79 mm. gives a capacity of 349 c.c. It operates on the usual two-stroke principle, with crankcase compression, but a feature is the automatic air valve mounted on the transfer port, which permits of a small quantity of air being sucked in on the upward stroke of the piston, and thus entering the cylinder in advance of the explosive charge. It is claimed that this absolutely eliminates "four-stroking" under all conditions on the road. A two-speed gear is incorporated, and the final drive to the rear wheel is by $\frac{7}{8}$ in. belt.

The back wheel is sprung in a vertical direction by means of coil springs housed in the large diameter carrier support, which permits of a movement of 2 ins. to the wheel. For all practical purposes the belt tension is unaffected in any position of the wheel. The spring fork is a Saxon, fitted with rim brake, the foot brake working on the outside of the belt rim. An oval tank fastened to the frame by metal straps holds 1½ gallons of petrol and 3 pints of oil.



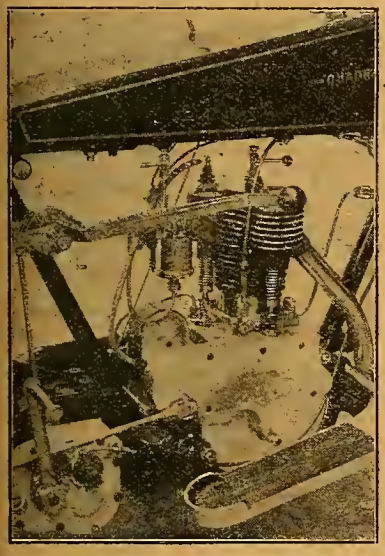
The 3 h.p. Paragon two-stroke, which has a neatly-sprung rear wheel.

Unconventional Engine Design—The Precision and New Quadrant.

Stand Nos. 207-95.
Baker, F. E., Ltd., "Precision" Works, King's Norton, Birmingham.

AN unorthodox machine which bristles with interesting features, the Precision motorcycle, attracts considerable attention, and it is well that Messrs. F. E. Baker, Ltd., have provided ten models for examination. The machine was described in detail in our issue of October 15th, so that it will suffice briefly to point out the interesting features which should be noticed.

The pressed steel tank forms the horizontal frame member and the head and seat lugs. The tank is formed in two halves and welded together, and as it has only one compartment, for petrol, there should be no trouble with leaks.



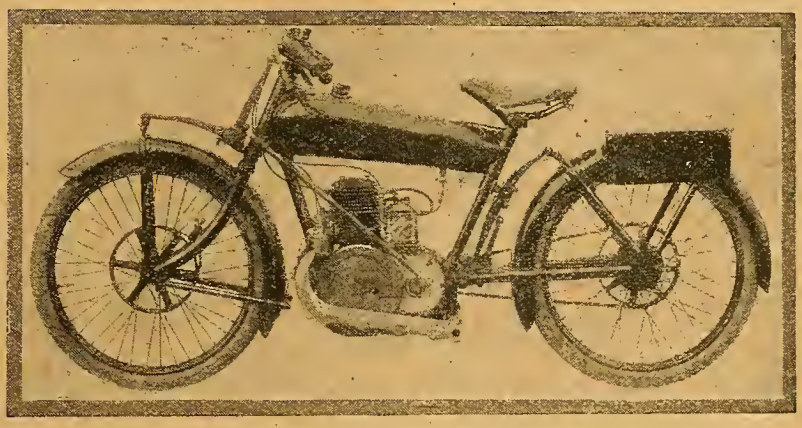
Quadrant engine and gearbox. Note the unusual position of the valves.

The front and rear springing by semi-elliptic leaf springs is very original, the front spring has been accommodated by cutting it in half and fixing the two halves at right angles to one another in the pivoted cradle.

The large mudguards are pressed from 18-gauge steel and are riveted to the frame, thus strengthening it considerably, The carrier consists of a metal box welded to the rear mudguard. The power unit is the standard 74 mm. by 81 mm. 3½ h.p. Precision two stroke.

The engine and gearbox are formed as a single unit, and the gears are obtained on the same principle as the Enfield gear. Two chains and sprockets take the drive from the engine, and by an expanding wedge bar either sprocket can be put into use. The ordinary rear brake is replaced by a contracting band brake, which works on the countershaft.

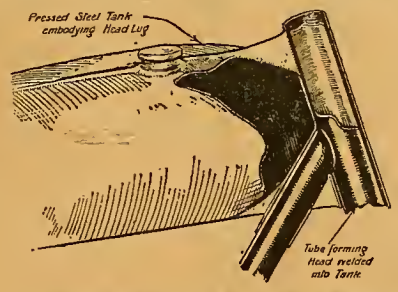
The engine and gear casing carries the oil supply, which is distributed by the magneto driving chain, and accordingly no trouble through under lubricating of the gears is possible. To absorb shocks in the chain drive devices are incorporated in the countershaft and back wheel sprocket.



A machine constructed throughout on unorthodox lines—the Precision.

Stand No. 121.
March, Newark and Co., Ltd., 45-53, Lawley Street, Birmingham.

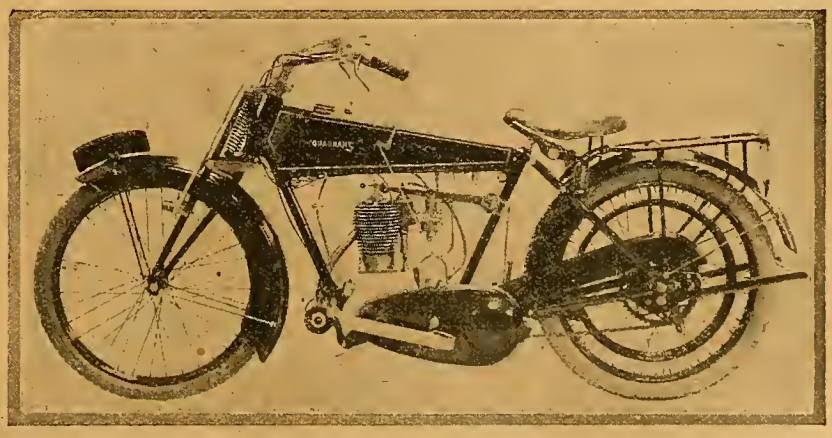
QUADRANT machines are well known as being one of the pioneers of motor cycling, and the latest models, as seen on this stand, are worthy of the high reputation they have to support. The two motorcycles are big singles, the 4 h.p. model having a bore and stroke of 87 mm. by 110 mm., giving a cubic capacity of 653 c.c. The top tube is straight, and is enclosed by the large saddle tank finished in black, with gold lines. The drive is all-chain, a slipping device being incorporated with the engine sprocket and a cushion drive with the rear wheel sprocket. The first step of the transmission is totally enclosed and the rear chain has a guard, thus making the final drive easy of access. The Sturmey-Archer three-speed gearbox is fitted, and the clutch is handlebar controlled.



The original Precision head design incorporating the front of tank.

The big 6 h.p. model has a bore of 95 mm. and stroke of 110 mm., giving a cubic capacity of 780 c.c., and it is noteworthy by reason of the combined engine and three-speed gearbox unit. Both Quadrant engines retain their unusual valve arrangement of the inlet valve at the rear of the engine and the exhaust valve at the side. The inlet valve is actuated by a small camshaft carried across the engine, and on the big 6 h.p. engine this is strengthened and provided with gearwheels, as it forms also the layshaft of the gearbox. By this means there is a considerable saving in material and in space, and the big engine fits exactly the same frame as the 4 h.p. pattern. The clutch on this model is a large Ferodo-lined cone, situated in the back wheel. The brakes actuate on V rims both front and rear.

Another interesting Quadrant production is the scooter, which has a two-stroke engine arranged in front of the rear wheel, and drives direct by a single chain. A saddle is provided, and the machine is very well mudguarded. The footboards and fork are both sprung.



The pleasing lines of the new single-cylinder Quadrant.

Arrival of the Raleigh—Radco Improvements.

Stand No. 64.
Raleigh Cycle Co., Ltd., Lenton, Nottingham.

ALTHOUGH this is the first time a Raleigh motorcycle has been exhibited at Olympia, the machine has been undergoing exhaustive road tests for nearly five years, so that prospective purchasers need not be afraid of getting a new and untried design.

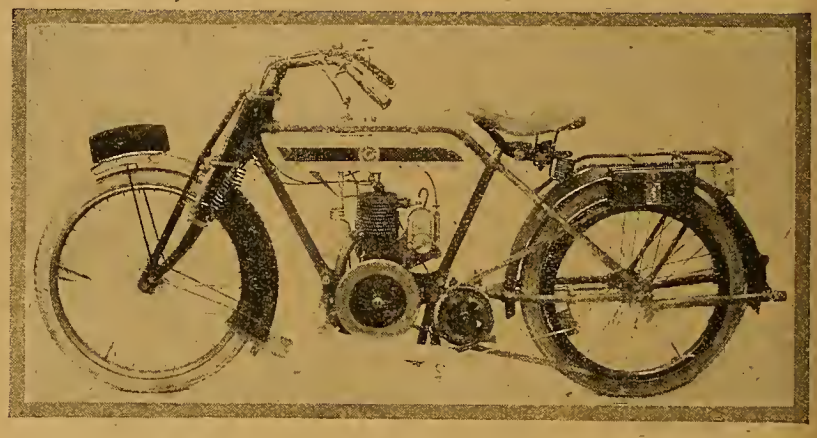
The engine is of the horizontally-opposed pattern, placed lengthways in the frame. Rated at 5 h.p., the cylinders have a bore and stroke of 77 mm. by 75 mm. and a total capacity of 700 c.c. The combustion heads are detachable and the valves are placed side by side and operated by a very simple timing gear, which employs no intermediate rockers. The tappets are adjustable, and the valve springs are conical in shape. Attention should be paid to the method of casting a portion of the induction pipe integral with the timing cover, to which the carburetter (A.M.A.C. one or two lever to order) is bolted direct. Thus only a short length of exposed induction pipe is necessary. Also, it allows the carburetter to be kept well out of the way of the rider's legs.

The forks pass through the front mudguard on the Raleigh, and so allow of a very wide guard being used.

The frame is of the duplex-tube type, and is very efficiently sprung at the rear on horizontal leaf springs. The gearbox is cast in bronze, and forms an integral part of the frame, as the rear portion hinges on lugs cast in it. As this hinge is in communication with the interior of the gearbox it is kept continually lubricated. Adjustment of the front driving chain is effected by sliding the engine, this being a simple matter. A spring shock absorber is located in the sprocket on the engine shaft. Both chain cases are solid affairs, and oil-tight. The clutch is of the cork-inset type, and operated from the handlebar.

Both wheels are easily detachable and also interchangeable, the drive being taken through a coned joint, which entails no backlash. The rear brake is internal expanding, working in the rear chain sprocket, and the front one consists of a pad wedging into the V of a dummy belt rim.

Three speeds are provided, operated by a long lever pivoting on the seat tube. Different gear ratios will be supplied, according to whether the machine is required for solo or sidecar work. A low saddle position—28 ins.—is obtained by virtue of the sloping top tube and tank; nevertheless, the latter holds 2¼ gallons of petrol and has exceedingly large fillers. The finish of the whole machine is in black, with tank lined red and gold. Its weight is 280 lb. and it will sell for 130 guineas.



The 2¼ h.p. Radco two-stroke has been improved in detail for next year.

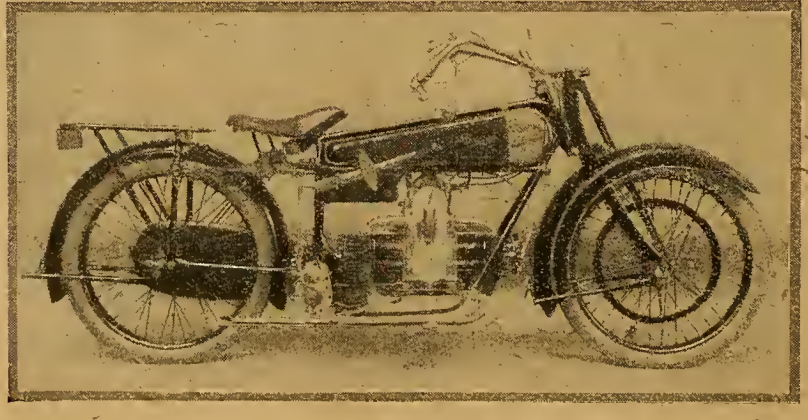
Stand Nos. 206-66.
Radnall, E. A., and Co., Dartmouth Street, Birmingham.

A VERY neat lightweight is shown on this stand by Messrs. E. A. Radnall and Co., Most motorcyclists will remember that the Radco, when it was first introduced in about 1912, was priced at 23 guineas, and although, unfortunately, the price is no longer possible, the workmanship and finish are as good as ever.

The engine is the well-known 2¼ h.p. Radco two-stroke, and is similar to earlier models, with the exception of one or two detail improvements. The frame has been improved considerably, especially in respect of the rear portion, which is built up with round tubes, giving a very large wheel clearance. The rear fork ends are constructed to take 6 in. heavy-type hubs, and the whole of these alterations add considerably to the rigidity of the machine.

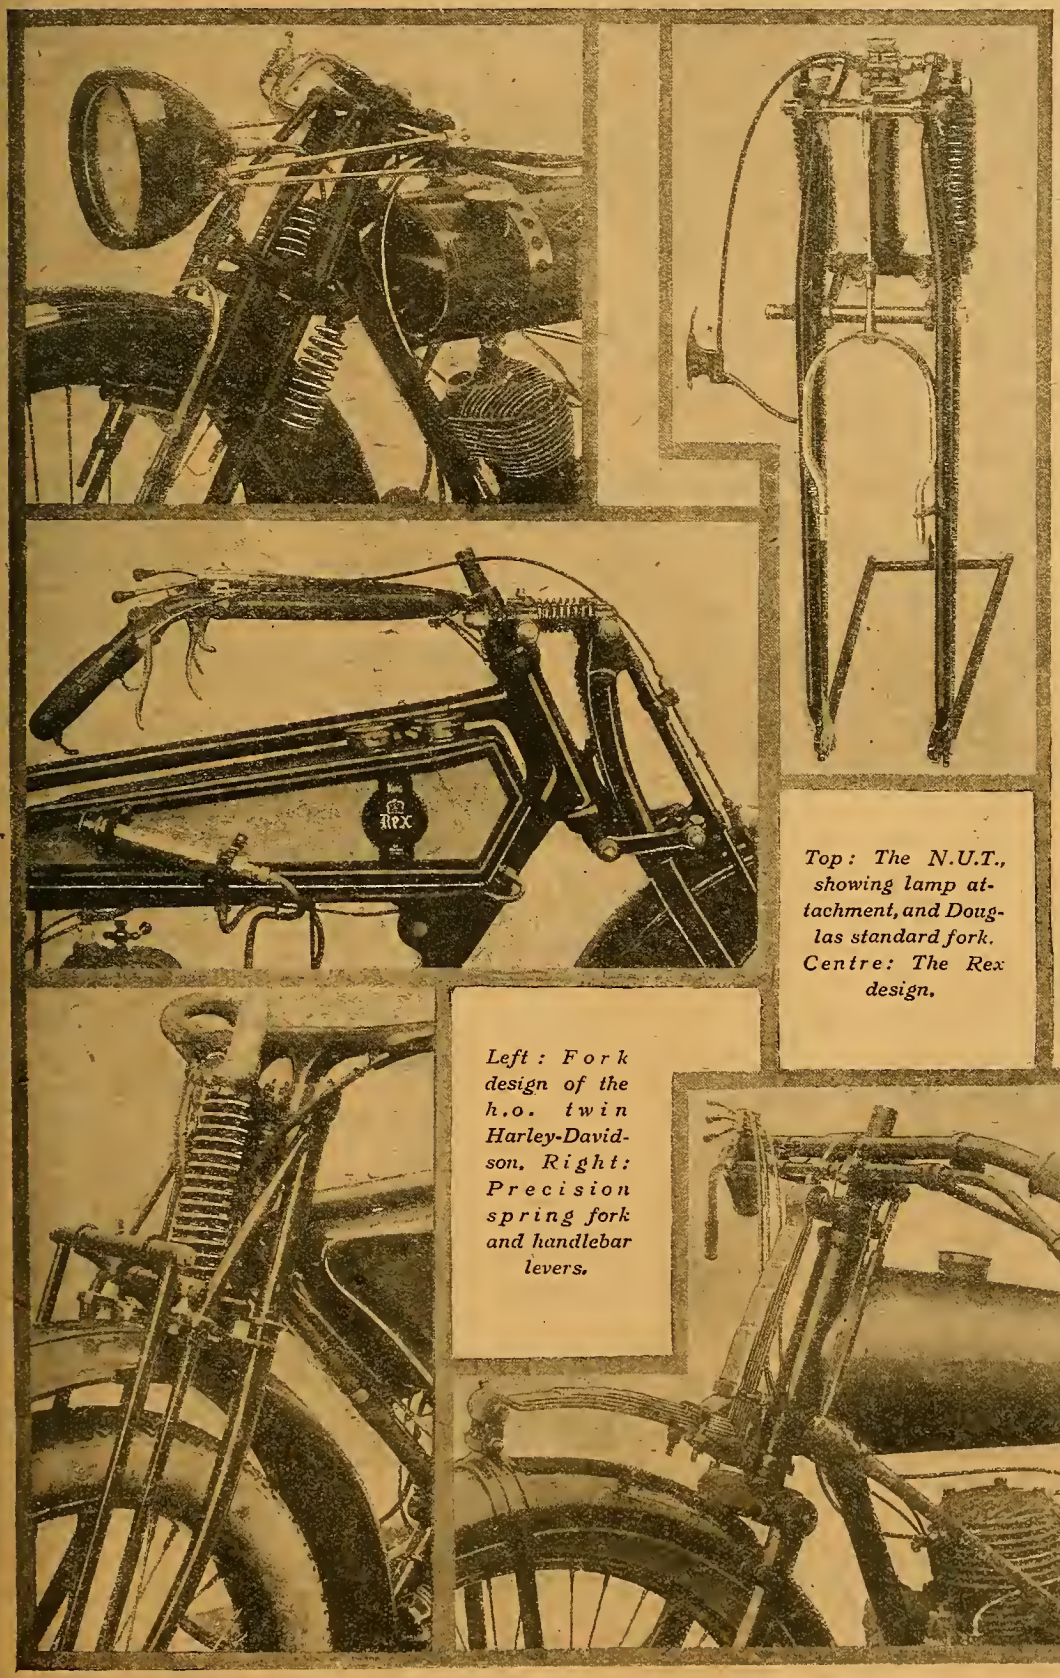
Round tubes are now employed in the rear portion of the Radco.

Footboards are fitted as standard, and these are supported on rubber-cushioned rods—a device which deadens all vibration to the foot. The toe pedal to the rear brake has been discarded, and the new models are fitted with an improved heel brake, which is much more convenient and get-at-able.



The 5 h.p. Raleigh is second to none on the point of appearance.

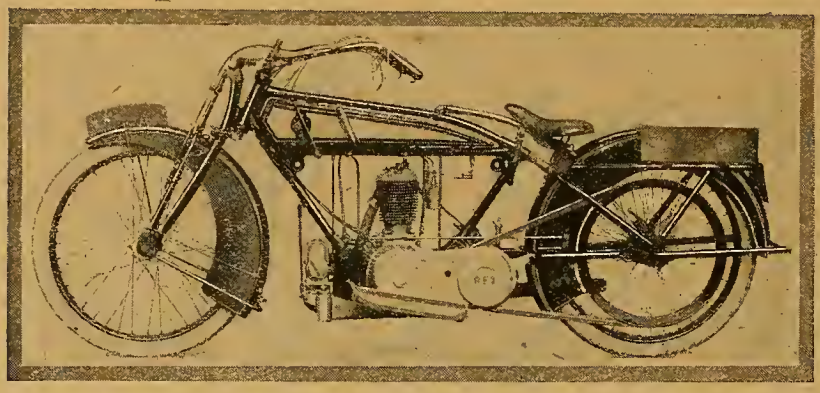
SOME HANDLEBAR AND FORK DESIGNS.



Top: The N.U.T., showing lamp attachment, and Douglas standard fork. Centre: The Rex design.

Left: Fork design of the h.o. twin Harley-Davidson. Right: Precision spring fork and handlebar levers.

Reading Standard Improvements—Rex Sidecar Single.



The 4 h.p. Rex is a single-cylinder mount equally suitable for solo or sidecar work.

Stand Nos. 119-195.
Watson, Stanley J., Berners Works, 37, Sheen Road, Richmond, London, S.W.

THE Reading Standard has improved out of recognition since its original introduction to this country, and the models exhibited will be found to be of most advanced design. The engine is of large cubic capacity—3⅜ ins. bore by 4 ins. stroke—and is rated at 10 h.p. It follows standard American practice to a great extent, and incorporates what is rapidly being recognized as an essential feature—mechanical lubrication. The power unit is especially commendable for its clean and well-arranged appearance.

A three-speed gearbox with gear wheels and sliding dogs of very ample proportions is fitted, and a noteworthy feature is the inter-connecting of gear control and clutch lever, so that a change cannot be made until all driving load is off the engine. The kick-starter is on the off side, thus conforming with English requirements.

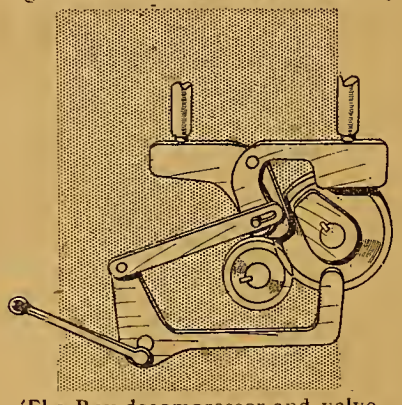
Visitors to the stand should particularly note the large tanks fitted (three gallons of petrol and three quarts of oil can be carried), the high quality of the mechanical and general finish of the machine of the popular large-powered sidecar machines.

We have heard nothing but praise regarding the performance of the first few 1920 machines which have seen road service so far, and feel confident that the Reading Standard will speedily become one of the popular large-powered sidecar machines.

Stand No. 55.
Rex Motor Manufacturing Co., Ltd., Earlsdon, Coventry.

EVER since the birth of the motor-cycle, the Rex Co. has been famed for its design, and the Rex of the season 1920, which, except in small details, is the Rex of 1919, is true to its forerunners.

For this season the concern is concentrating upon the single-cylinder model, which, although very little heavier, if at all, than the average single, has a sufficiency of power for sidecar work. The cylinder capacity is 550 c.c., the bore being 84½ mm. and the stroke 98 mm. The mainshaft runs on roller and ball bearings, while the crank pinion has twin cage rollers. Lubrication is studied very seriously, and is carried out on car lines by a mechanical pump through crankcase and sump to the sight feed on the side of the tank, whence it runs through a distributor to cylinder, piston, and bearings, and back again to the sump. The tank is finished purple, and with a purple sidecar to match certainly makes one of the most handsome outfits in the Show. It is sloping and tapered, and has a capacity of 2½ gallons.



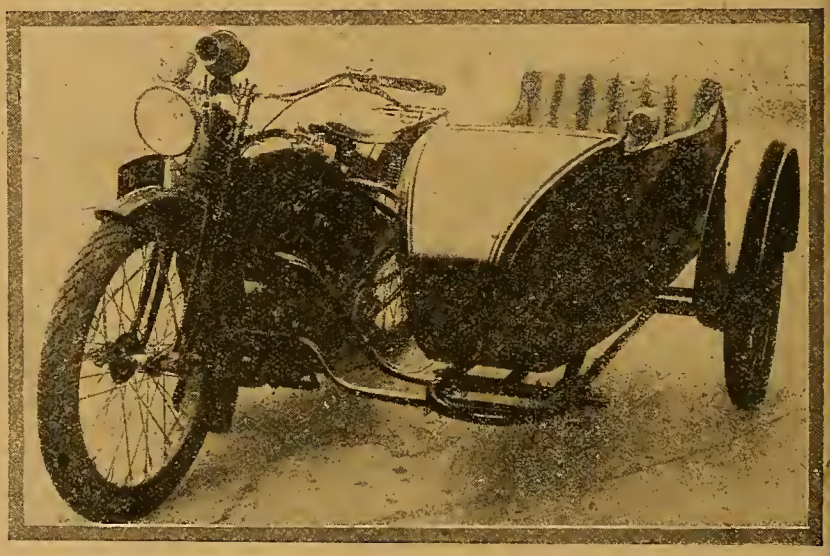
The Rex decompressor and valve gear.

The gearbox is a Sturmey-Archer three-speed, having a hand-controlled clutch, and with 28 in. wheels gives ratios of 5.2, 8.3, and 13.6 to 1. Other features to be noticed include the cantilever-sprung seat pillar, large carrier with permanent box, detachable wheels, and business-like footboards.

The single-lever A.M.A.C. carburetter is standard, as also are Brampton front forks. Sidecar lugs are cast integral with the frame lugs, and are so disposed as to allow the fitting of the sidecar on either side.

While limiting themselves to a single model as regards the machine, plenty of variety is found among the sidecars. In addition to the English models, a Continental pattern is shown fitted to the right of the bicycle in accordance with the rule of the road of the rest of Europe. The registered design of boat body promises comfort and area for the passenger, spacious accommodation for tools and spares, without appearing the least ungainly. The spare wheel is carried at the rear in a strong bracket, and having its tyre held by the lower fixture, cannot vibrate against the body on the worst roads. The chassis is attached to the machine at four points; the connections are braced by a tube running from the forward coupling to the rear.

Developments in the commercial sidecars are exhibited, and embrace tradesmen's carriers and the newspaper cars which have done, and are doing, yeoman service among town and country journals. Another interesting item is a sidecar designed for extra heavy work, with a steel body and 28 in. by 3 in. tyre.



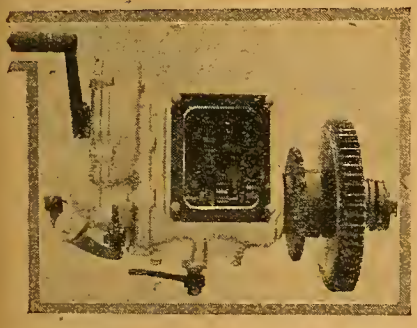
The 10 h.p. Reading Standard outfit is probably the highest powered combination on the market.

Rover Detail Improvements and New Sidecar Body.

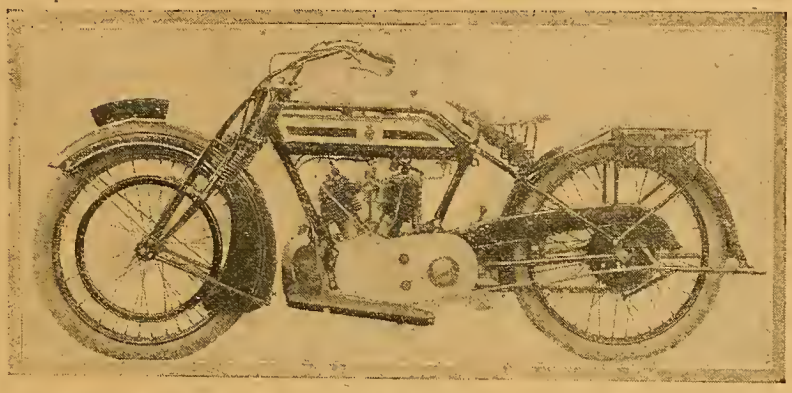
Stand No. 79.
The New Rover Cycle Co., Ltd., Queen Victoria Road, Coventry.

THE most noticeable alteration in the Rover for 1920 is the redesigned fork, which is now very much wider in order to accommodate the new mudguard without excessive trapping. The spring links, taking end shocks, are fitted with larger bearing surfaces, and sideplay has been positively eliminated.

The 3½ h.p. standard model has now an all-chain transmission in place of the chain-cum-belt, though the popular T.T. model still retains its simple belt drive, and may be had either with or without a Philipson pulley. Two chains are used on the standard: a silent chain from engine to gearbox and a Brampton spring chain to the back wheel. This latter embodies in itself the functions of a shock absorber, and under test has been found in every way satisfactory. It is serpentine in form, and its springs automatically take up any shock that might prove harmful to an ordinary roller chain. The conventional front rim brake of last year's model has been superseded by one of the dummy belt-drum pattern now coming to the fore on account of its simplicity combined with practically no inconvenience to wheel removal. The rear brake follows last season's practice on the chain-driven model, operating internally on the chain sprocket. The big-ends are now equipped with roller bearings in place of the phosphor-bronze bushes previously fitted, and a less important item worthy of notice is an increase in the size of the toolbags.



The three-speed countershaft gearbox.

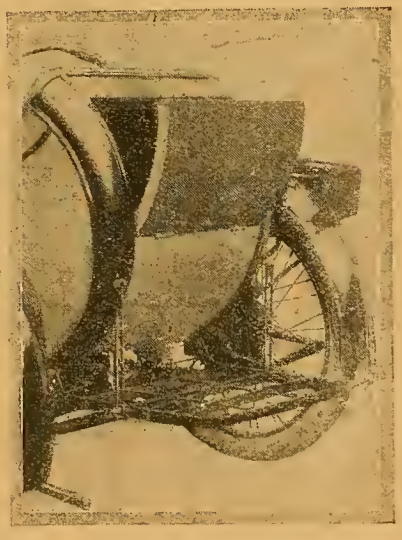


Transmission side of the 5-6 h.p. twin Rover. The dummy belt rim front brake will be noted.

Apart from the new fork and front brake, little alteration has taken place in the 5-6 h.p. twin, except in the matter of chain protection, the totally-enclosed rear system having given way to a chain guard over the upper portion of the chain, which quite sufficiently protects it from the elements, and renders the back wheel easily detachable. The tyres on the twin are 28 in. by 3 in. Dunlops, while the single has 650 mm. by 65 mm.

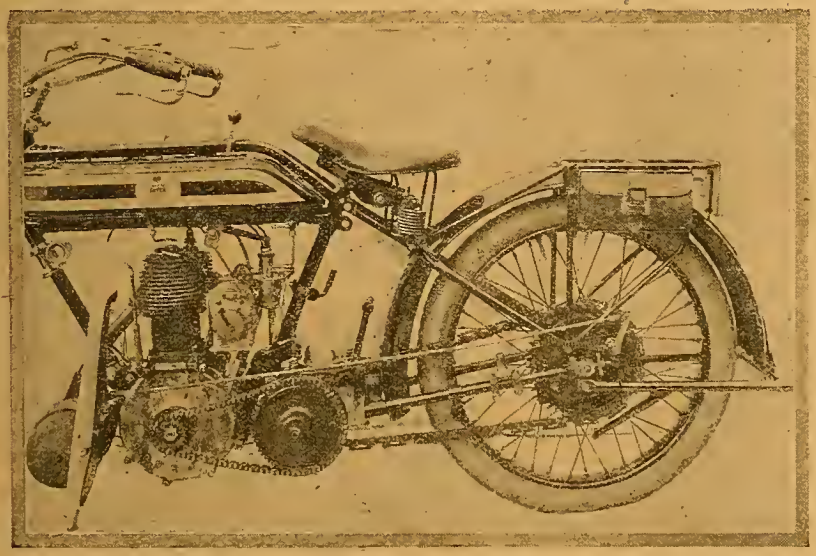
All models have received attention to their mudguarding arrangements, the new blades being very handsome and of 5-in. dome section. The gearbox is unchanged on either model, but the clutch, instead of cork insets, is of the Ferodo ring pattern, which stands up better in the hands of a careless driver, and every concern has, of course, to study possible unfeeling pilots. The gear lever is still taken up through the centre of the tank, where it is out of the way, yet close to the hand. The gear ratios are, on the twin, 5½, 9, and 17 to 1, while on the single they are 5, 8½, and 15 to 1. Cylinder dimensions are, for the single 85 mm. by 88 mm., and for the twin 70 mm. by 85 mm., their respective capacities being 499 c.c. and 654 c.c.

A notable improvement is observable in the Rover sidecar. The body has been entirely redesigned, and is now much longer and roomier, with far more leg room than previously. Also, a commodious locker is located in the bulbous back, which forms a means of carrying a can of petrol in addition to other sundries. The finish is quite up to the high Rover standard of coachwork, and the same may be said of the upholstery.



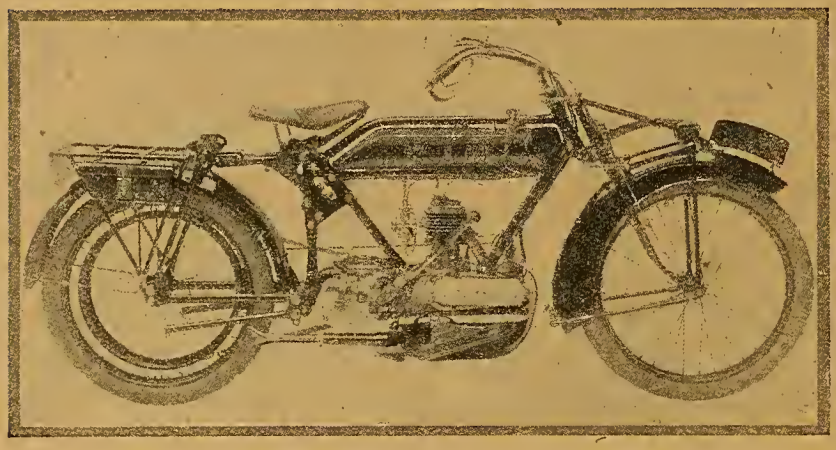
An improvement in the Rover sidecar is the new bulbous back body.

Altogether the Rover outfit, whether 3½ h.p. or 5-6 h.p., is one of those dignified-looking combinations that invariably attract admiration in any company.



The 3½ h.p. Standard Rover is now fitted with chain-drive. The Brampton spring chain forms the shock absorber.

The New 3 h.p. Royal Ruby—Rudge Programme.



The new 3 h.p. Royal Ruby embodies an inconspicuous spring frame.

Stand No. 101.

Ruby Cycle Co., Ltd., Cannel Street, Ancoats, Manchester.

ON this stand will be found examples of the latest 3 h.p. spring frame Royal Ruby (which was fully described and illustrated in our last week's issue), together with the spring frame 8 h.p. twin passenger machine.

The principal feature of the new 3 h.p. model is the spring suspension, both fore and aft, of the frame. To obviate wear no links are employed in connection with these springs, the eyes working on special roller bearings. Incidentally, should a spring frame not be desired, it can be converted in a few moments.

The 3 h.p. engine has a bore and stroke of 74.5 mm. by 80 mm., giving a capacity of 349 c.c., and operates on the four-stroke principle. It is made throughout by the company, as is the gearbox, which provides two speeds and is located on the countershaft. Transmission is by chain and belt, and a handlebar clutch and kick-starter are provided.

The chain is easily adjustable, and is enclosed in an aluminium case. The foot brake works on the belt rim, and has a device which ensures even pressure throughout the length of the shoe. Mudguards of good size ensure reasonable protection for the rider, and adjustable footboards enable a riding position suitable to persons of different heights.

The 8 h.p. model is fitted with a J.A.P. engine, and has a spring frame. Noticeable features of this machine are the large size of the pannier bags and the patented additional safety (duplex) stays from the steering head to the engine. A Sturmey-Archer three-speed gearbox is located on the countershaft, and transmission is by all-chain fully enclosed. An ingenious eccentric device operated by a hexagon head slides the gearbox to effect chain adjustment.

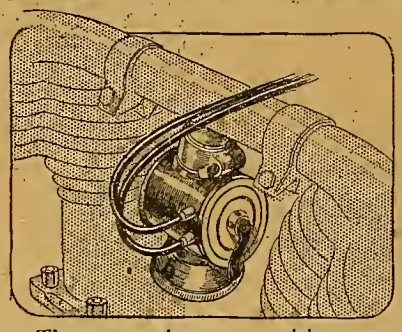
A commendable feature of the sidecar construction is the ample provision made for luggage. In addition to personal luggage and the spare wheel, two tins of petrol are securely slung on the underside of the grid.

E40

Stand No. 92.

Rudge-Whitworth, Ltd., Coventry.

THIS stand is very popular with everybody on account of the working models exhibited. The Multi gear cannot be properly demonstrated



The new carburetter position on the twin Rudge.

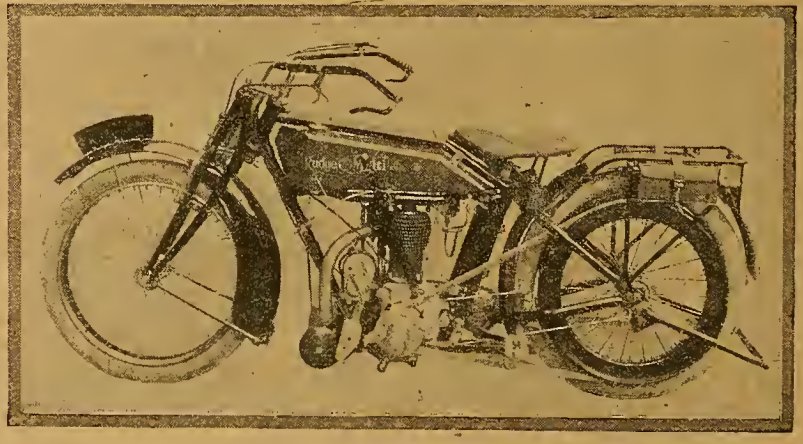
unless the machine is in motion, so Messrs. Rudge-Whitworth, ever enterprising, have supplied the necessary movement.

Practically no change has taken place in the Rudge machines for next year, but the sidecar is considerably improved. The body has been made wider in front and an adjustable foot piece to suit the needs of tall or short riders is placed under the mat. The chassis is a remarkably fine piece of work without any bent tubes, and the body quite luxurious. In addition to the seat locker there is another at the rear large enough to accommodate a suit case. The petrol can holder and luggage grid has the benefit of the springing, as does also the mudguard.

The Rudge engine has roller bearings to both ends of the connecting rod, and a single ring at the top and bottom of its pistons. The mainshaft runs on ball bearings. The 3½, 5-6 and 7-9 h.p. models have capacities respectively of 499 c.c. (85 mm. by 88 mm.), 750 c.c. (85 mm. by 132 mm.), and 998 c.c. (85 mm. by 88 mm.). The inlet valves are overhead and easily detachable, while the flywheels are large and carefully balanced. Vernier adjustment is incorporated in valve and magneto timing. The silencer is large and includes a long tail pipe.

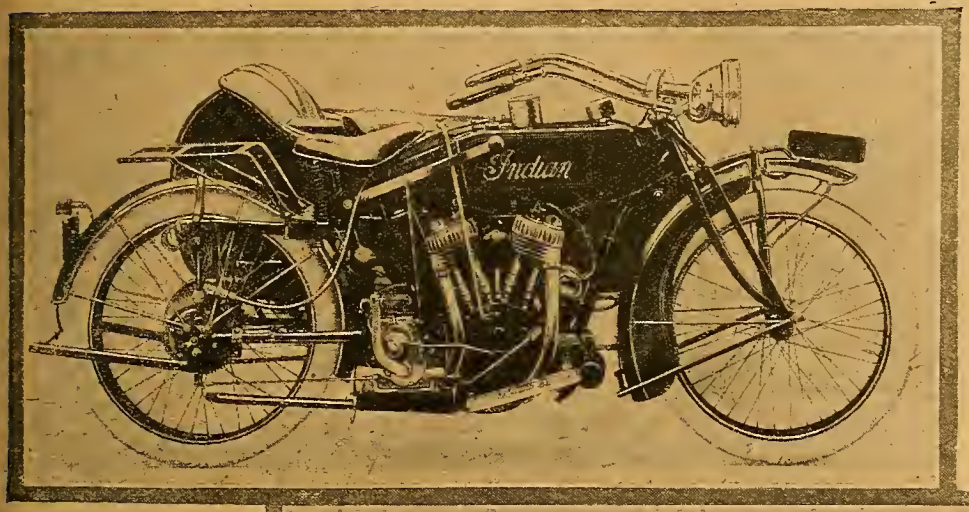
The tanks are finished in a dark olive and a paler green. The Isle of Man tank, as fitted to the T.T. and Multwin models, is particularly good, furnishing a very low saddle position. The filler cap should be inspected and the captive one on the oil tank, held in place by a spring, is also good. Carrying the oil in a separate tank gives the petrol tank a full two-gallon capacity.

The multi gear gives any ratio between 3½ and 7 to 1, 20 different positions of the lever being allowed for. The clutch is handlebar controlled, and footrests rubber covered. The pedals may be brought to their lowest position together to take the place of the second pair. The wheels are 650 mm. by 65 mm., with ribbed tyres and 10 gauge spokes. These tyres are identical with those on the T.T. winner of 1914. They are considered to be the fastest, safest, and most durable obtainable. The 3½ h.p. models Roadster or T.T. are priced at £90, the 5-6 h.p. single at £98, the 7-9 h.p. Multwin at £107, and the sidecar at £33 10s.



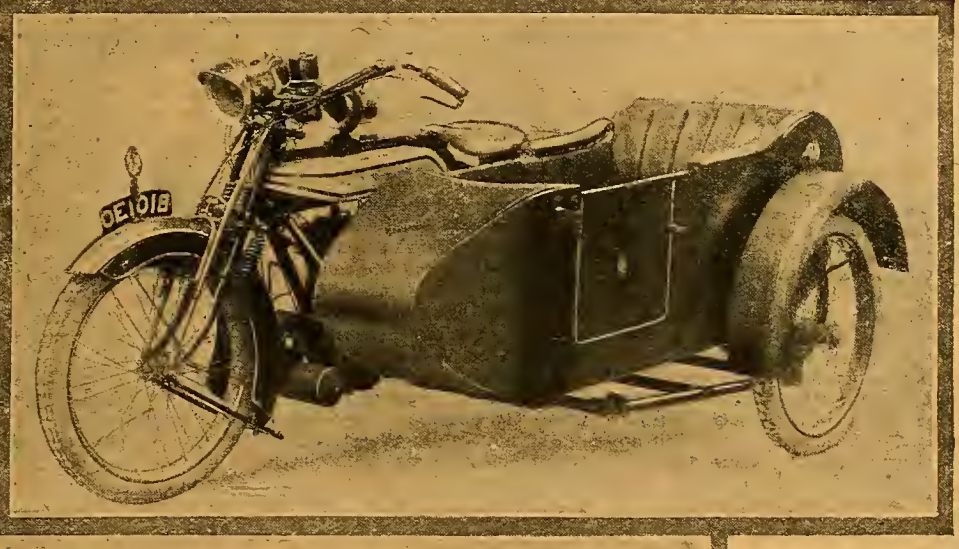
The 3½ h.p. T.T. roadster Rudge-Multi.

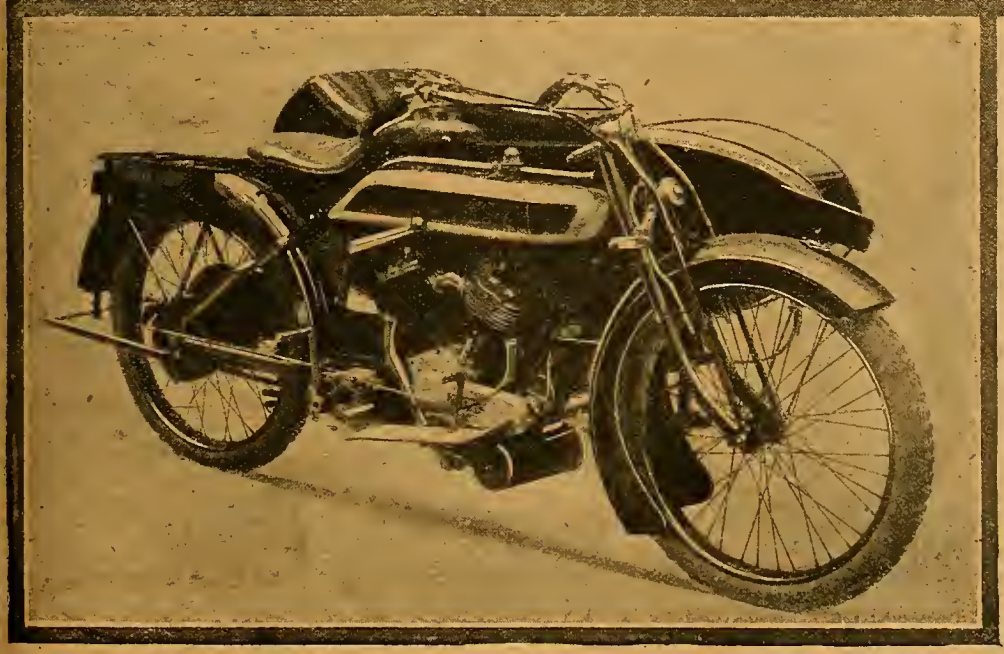
REPRESENTATIVE TYPES OF PASSENGER OUTFITS.



The 7·9 h.p. Indian incorporates leaf springing fore and aft and is particularly well equipped.

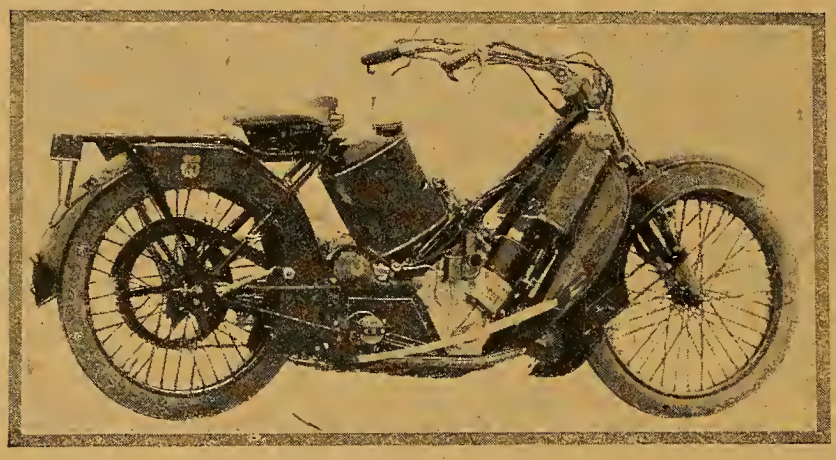
The famous "Big Four" Norton. All-chain drive and the Sturmey-Archer countershaft gear are standard.





The 8 h.p. Dot is of strong construction. The special frame design permits of a very low riding position.

Scott Improvements and New Features.



Still the sole representative of its class—the Scott water cooled twin two-stroke.

Stand No. 122.

The Scott Engineering Co., Ltd., Shipley Work, Saltaire.

FOUR models of this firm's two-stroke are on view, the touring model solo and with sidecar, another with semi-T.T. handlebars, and the T.T. machine. With the exception of the fitting of a double sight drip-feed lubricator at the foot of the tank just under the eye of the rider, practically no alteration has taken place in last year's design. Owing to its low engine position and scientific design of steering column and frame generally, the Scott is perhaps the finest to ride among all our excellent machines. Those who have seen it in competition will appreciate what can be done by a good "corner man," and its performances in the Tourist Trophy races are instances of its excellent behaviour in this respect.

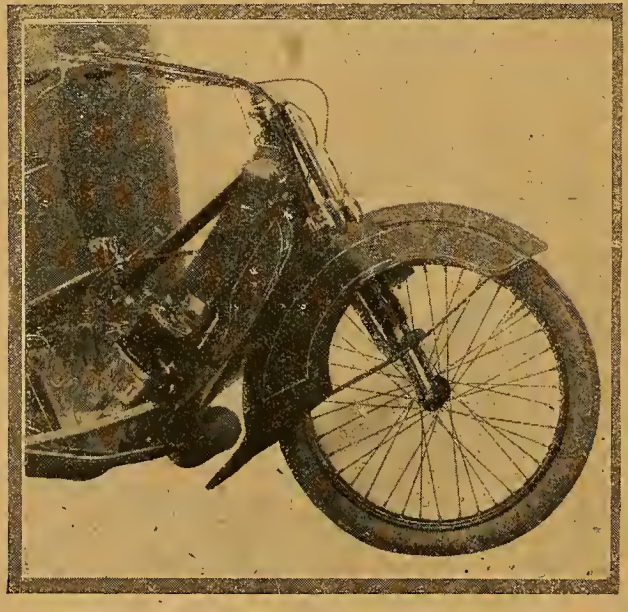
The engine is a water-cooled twin two-stroke, with side-by-side cylinders. It has a torque equal to a four-cylinder four-stroke engine, and consequently is light on transmission and tyres. The connecting rod big-ends are fitted with roller bearings, the races being pressed in and removable when necessary, and the piston has three rings, two at the top and one at the bottom. A Binks carburetter and Thomson-Bennett magneto are fitted as standard.

The absence of loose clips of any sort is noticeable, everything requiring attachment to the frame having a special lug brazed up with the whole. We particularly noticed the stop to the kick-starter as an example.

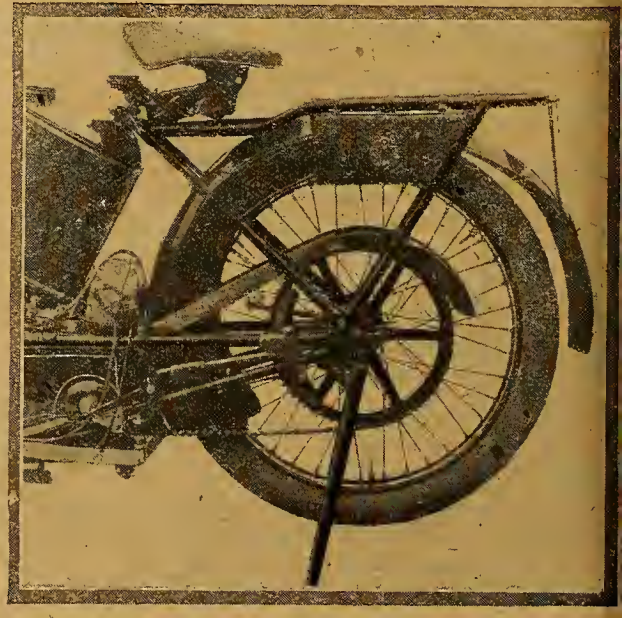
The two-speed gear is the simplest possible, relying only on two expanding rings, one for high and one for low gear. It will stand up to all sorts of abuse, and it is safe to say that nothing more reliable in the way of change-speed devices has yet been evolved. Two chains having different sprocket ratios constitute high and low gear between engine and countershaft, whence another chain takes the energy to the back wheel. This last chain is not cased in, but has a deep guard over its upper portion to protect it from the ill-effects of rain and mud.

Thorough mudguarding has always been a feature of this machine, and the new model is no exception. Wide valances are fitted to the rear as well as the front guards, the latter having a splasher in addition. Broad shields reaching below the curved aluminium footboards further protect the rider, while side and under shields all quickly spring into position, ensure a clean engine. Other noteworthy details include the seat pillar filler cap, the long shoe of the rear sprocket brake, and the concern's patent design of spring fork.

The sidecar, finished to match the machine, has a large comfortably-upholstered body, sprung on the cantilever principle. The moving parts are all phospbor-bronze bushed, and, with the screw-down greasers provided, should give indefinite service. The main portion of the chassis is an isosceles triangle, strengthened, of course, with extra members, attached to the machine at four points. The solo machine costs 110 guineas, while the combination is sold for 140 guineas.



The new Scott spring fork and front guard. The former has a sump containing a month's supply of oil.



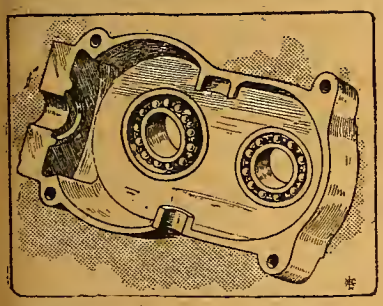
The protected position of the magneto is one of the many good points on the Scott.

Two representative two-strokes, the Sparkbrook and Sun-Vitesse.

Stand No. 77.

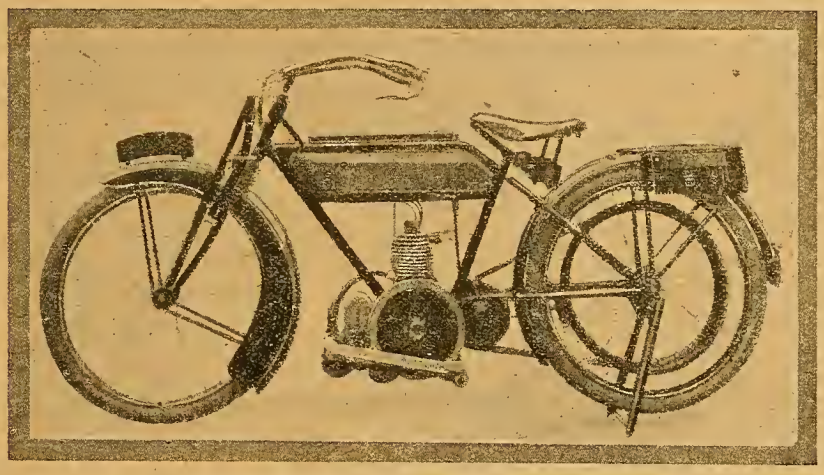
Sparkbrook Manufacturing Co., Ltd., Paynes Lane, Coventry.

HERE we find an exceedingly sturdy and well-finished two-speed lightweight of 2½ h.p., fitted with the well-known Villiers engine. The carburetter is a B. and B. two-stroke model and the magneto a C.A.V. KU1. The tank is attractively finished in green and black and is supported on brackets brazed to the frame, instead of the commoner top-tube clips. Mounted on the tank in a convenient position is a Best and Lloyd sight-feed lubricator, supplying oil to the engine. The wheels are 26 ins. by 2 ins., shod with Dunlop tyres; they have bearing caps and felt washers to exclude rain and grit. The spring forks have a specially-designed long bearing link, which ought to run many thousands of miles without developing play. The saddle is a Brooks B150. The transmission is chain-cum-belt over a large diameter rear pulley. The gearbox has its pinions always in mesh; these are made from special gear steel and run on self-aligning ball bearings. Lubrication is amply provided for in a small reservoir on the top of the gearbox, which slides along



The Sparkbrook gearbox has self-aligning ball bearings.

the bottom bracket tubes for the adjustment of the chain. This year the gear lever is mounted on a special lug brazed to the frame and works in a gate on the tank top. Long aluminium footboards are fitted, which, by the undoing of a single nut, may be swung back out of the way to facilitate cleaning or repairs. The finish is black as far as possible, including handlebars and hubs. Some half-dozen machines are exhibited. The price of the single speed is £59 and the two-speed model £65.



The 2½ h.p. Sparkbrook with Villiers 2-stroke engine.

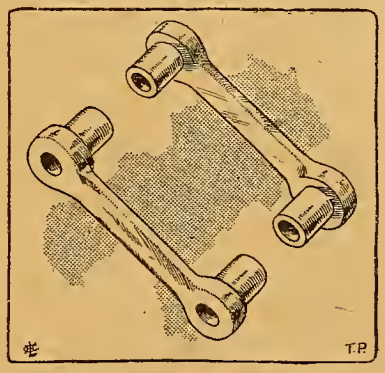
Stand No. 57.

Sun Cycle and Fittings Co., Ltd., Aston Brook Street, Birmingham.

1920 Sun-Vitesse motorcycles are displayed in their various models on this stand.

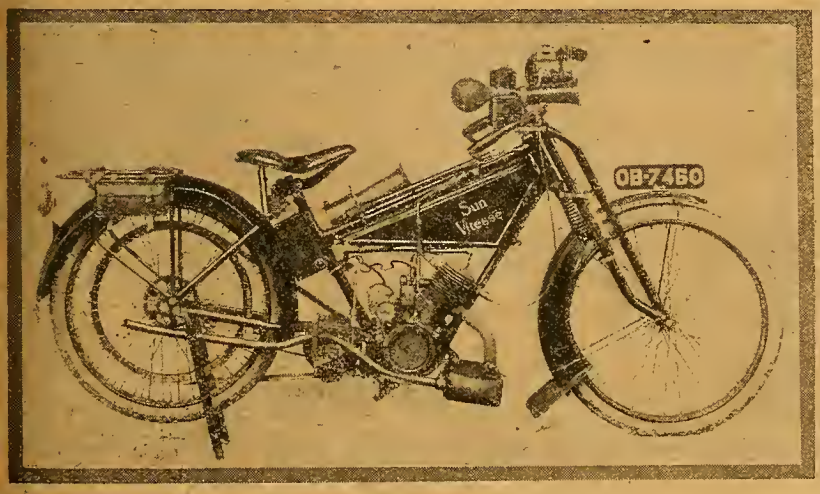
The engine is set on the slope, running parallel with the front tube. The principal claims made for the new model are the simplicity in the construction of the engine and the frame and the compactness in which the whole of the following important members are carried.

The cradle, which is cast in one piece, has three bolt holes for the engine, two bolt holes for the footboards, and further bolt holes on which the two-speed bridge is carried. By disconnecting the exhaust pipe and removing three nuts on the cradle, the engine, complete with carburetter and magneto, can be lifted bodily from the frame. Simplicity and efficiency in the engine have been aimed at by the construction of a one-piece crank chamber, with a single-bearing scientifically balanced crankshaft, which is so made that no crankcase compression can be lost. A sectional model of this engine is shown as well, so that those interested may see the exact working of it.



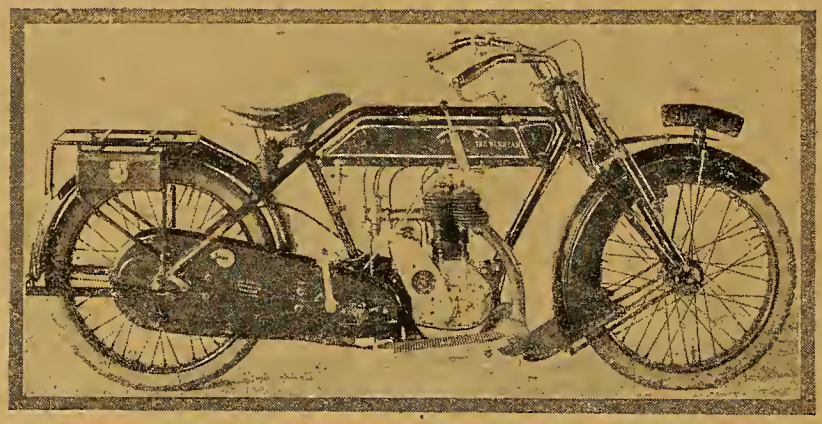
Specially long bearings are fitted to the Sparkbrook fork links.

The flywheel is in the usual position on the left-hand side of the engine, and the drive is by means of a chain to the gearbox and thence by belt to the back wheel. Between the driving sprocket and the engine is placed another sprocket for the magneto drive, the magneto being placed on the top of the crankcase just behind the cylinder. The back mudguard is of a 7¼ in. section, and the front, though narrower, is well equipped with side valances. The whole machine, of which single-speed and two-speed models are made, is tastefully finished in black and gold.



The 2¾ h.p. Sun-Vitesse is a distinctive-looking little mount.

Sunbeam's Adopt Detachable Wheels and Leaf Spring Fork on the 3½ h.p.



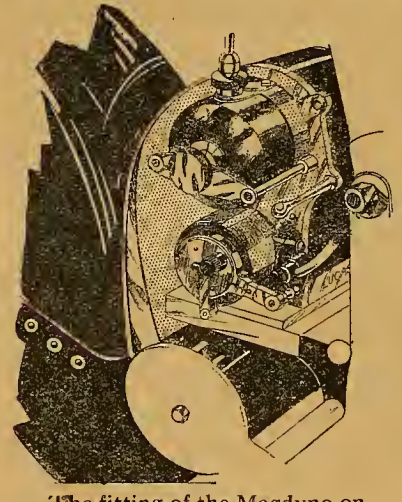
Note the new type of front fork fitted to 1920 3½ h.p. Sunbeams.

Stand No. 49.

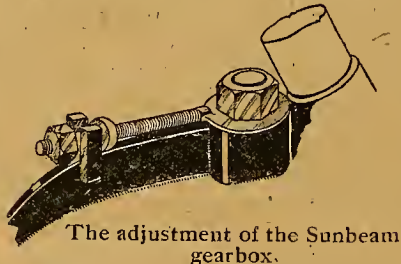
John Marston, Ltd., Sunbeamland, Wolverhampton.

WHILE the 8 b.p. model, except for the substitution of the Lucas Magdyno in the original magneto position, remains practically as last season, the 3½ h.p. has been modified in several ways, perhaps the most noticeable of which is the front fork. This is shown with a leaf spring parallel with the front mudguard, which is now 5 ins. in width, and has a large splasher at its foot protecting the engine from mud.

The silencer is now welded up in one piece, and the cylinder head fins are of slightly different formation from those of last season. Otherwise the engine is unchanged, its dimensions being 85 by 88 and its capacity 499 c.c. The carburetter is an A.M.A.C., while an E.I.C. magneto is standard. The new rear brake should be noted. It is now of the internal-expanding type operating on a drum formed by the rear chain sprocket, and is connected to its large size pedal by a Bowden cable. The front brake shoe also is worthy of a few minutes' attention for by unscrewing its securing nut half a turn or so it may be released from its slot, enabling the wheel to be pulled clear.

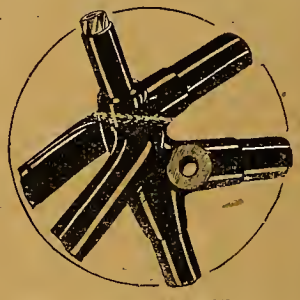


The fitting of the Magdyno on the Sunbeam.



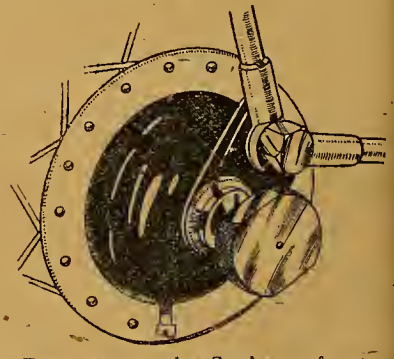
The adjustment of the Sunbeam gearbox.

The wheels are now detachable and interchangeable, a spare being optional on the sidecar outfits. The back wheel is secured to the rear sprocket by pegs meshing with holes in a flange of the hub instead of by the more usual dogs. By undoing a nut, withdrawing spindle and taking out a small distance piece, the wheel may be changed in a matter of minutes without disturbance to the sprockets or chain cases in any way. The wheels are 650 by 65, fitted with Dunlop tyres on the T.T. model and Bates on the roadster. The hubs are large and waterproof, the front especially having a neat deflector resembling more than anything else, a miniature shrapnel helmet, effectively throwing off mud running down the front fork.



Sunbeam seat pillar.

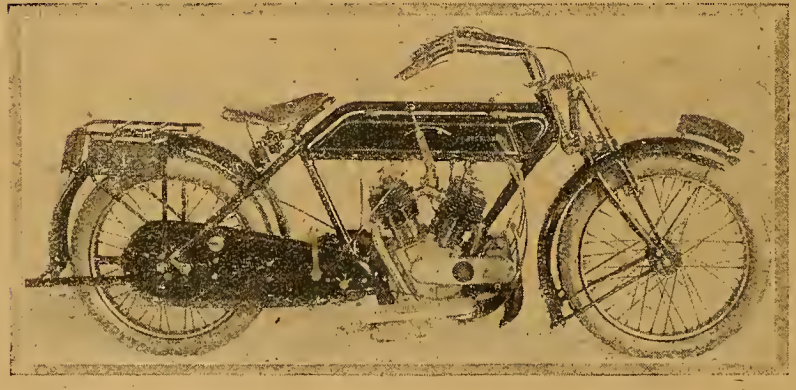
The same gearbox is used on either model and its works may be inspected in a skeleton model on the stand. It should be noticed that two separate sliding dogs are used and that all the six pinions are constantly in mesh. The ingenious cam system effecting the requisite right and left movement in the dogs should not be missed. The gears are oiled through the sight feed, which has a two-way tap to engine or gearbox.



Dust cap on the Sunbeam front wheel.

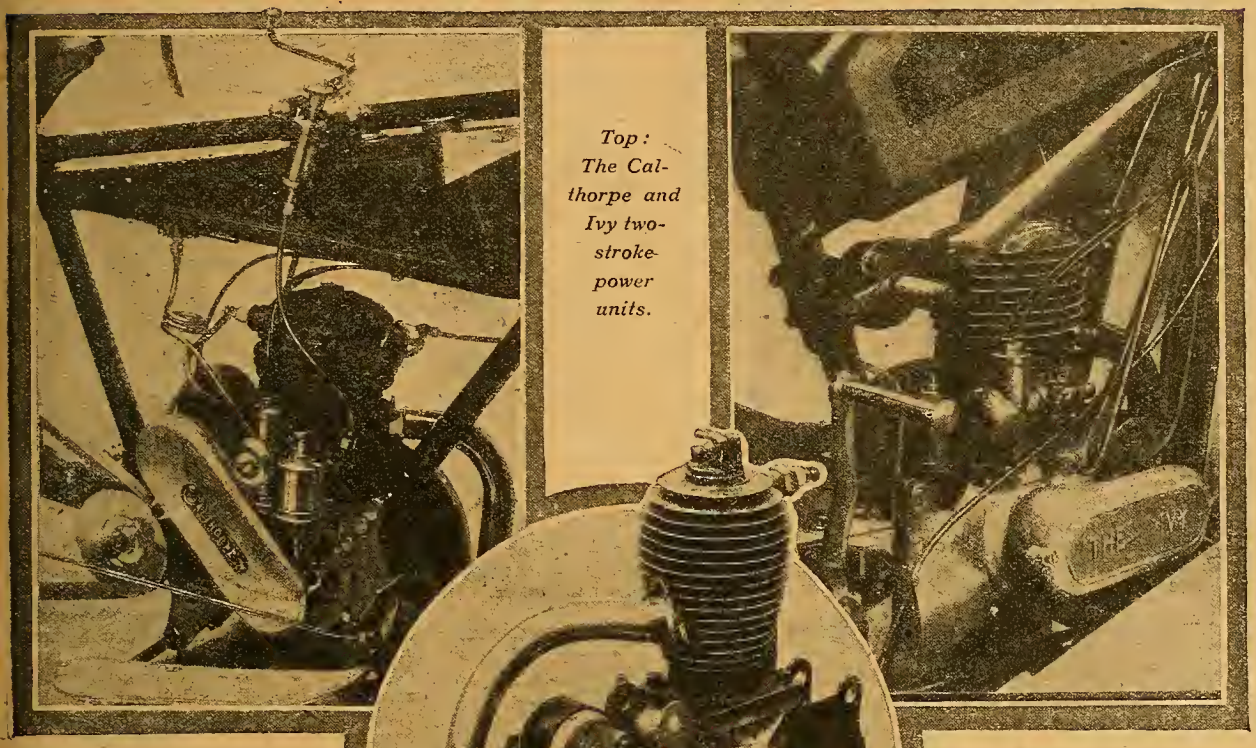
Both models have roller chain transmission in oiltight chain cases, the forward case being an aluminium casting. They are easily detachable, and the rear one has an inspection port closed by a circular cover.

Both sidecars are very handsome and roomy vehicles, the heavier model possessing every useful refinement ever crowded on a chassis. Sectional engines and individual parts are displayed in variety for the benefit of discerning purchasers.

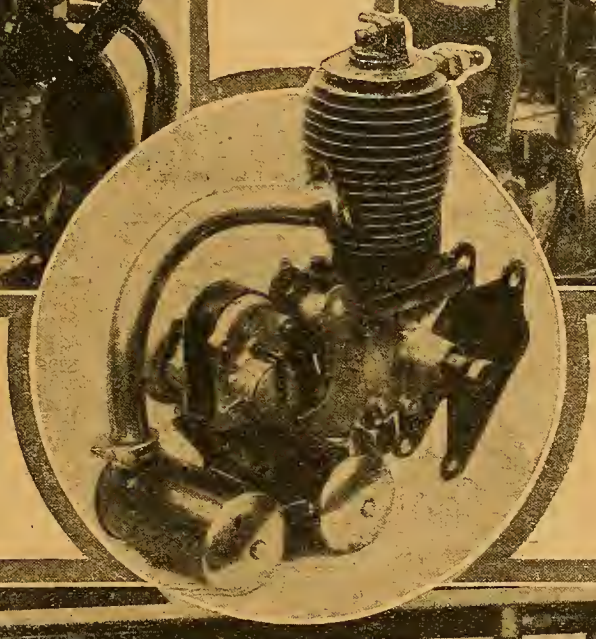


The luxurious 8 h.p. Sunbeam—an ideal passenger machine.

TWO-STROKE AND FOUR-CYLINDER ENGINES.

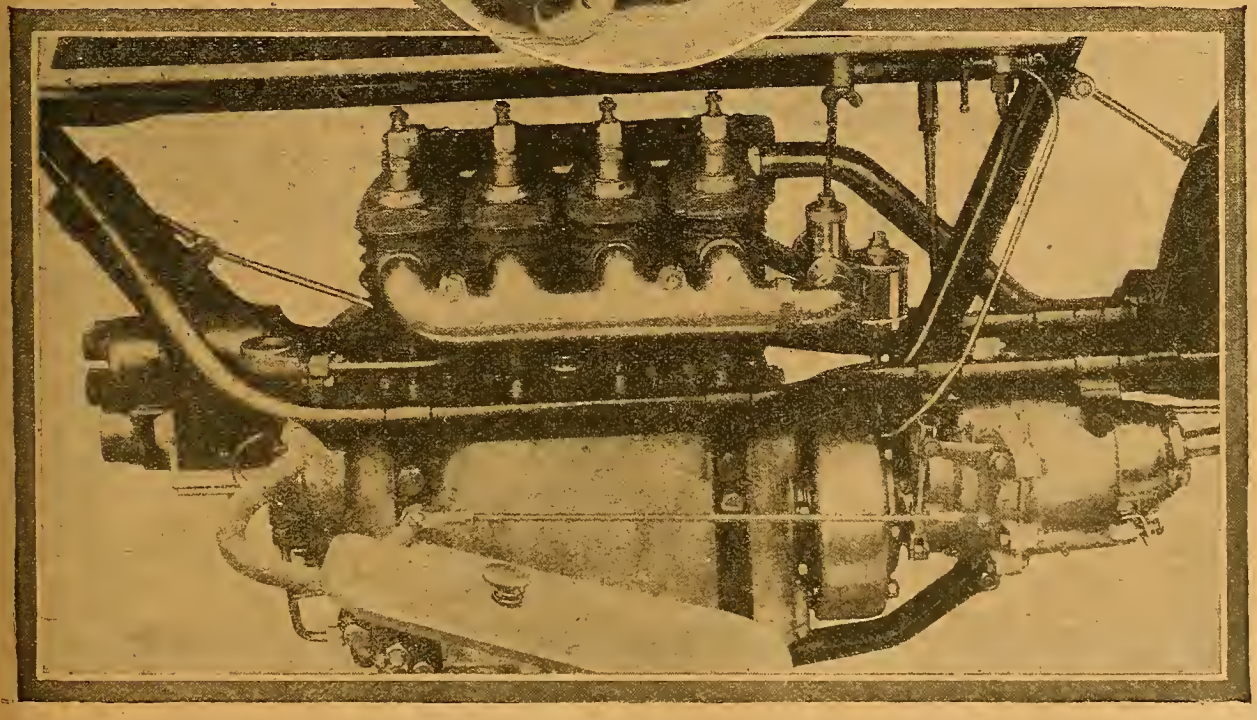


Top: The Calthorpe and Ivy two-stroke power units.



Centre. The popular Villiers two-stroke power unit. Note the dual silencers.

Bottom: The 7 h.p. four-cylinder F.N., which has made its re-appearance.



The Trusty Triumph Programme—Velocette Two-stroke.

Stand No. 96.

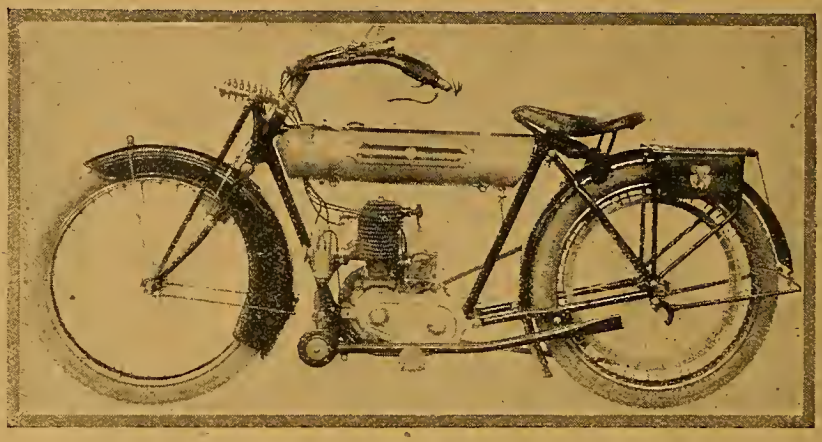
Triumph Cycle Co., Ltd., Priory Street, Coventry.

THREE Triumph models are shown—two being variations of the 4 h.p. model, and the other the lightweight. A new departure is seen in the all-chain drive machine, which has a gearbox of Triumph manufacture. It operates on the sliding gear-wheel principle, low gear being obtained by internal dogs engaging with projections on the mainshaft, middle by the teeth of the wheel meshing with another wheel on the layshaft, and top speed by the wheel sliding bodily into a larger wheel with internal teeth.

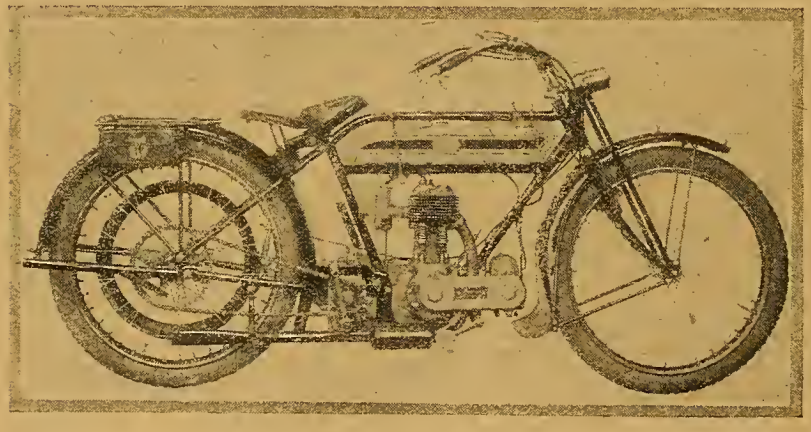
A very ingenious shock absorber is embodied, by means of which all engine snatch is absorbed by a strong spring. A metal plate clutch having alternate plates of copper and steel, and operated from the handlebar, is fitted, and particular notice should be taken of the chaincase, which encloses the front driving chain. This case is absolutely oil-tight, and it is from here that the gearbox receives its lubricant. The method is to pour a pint of oil into the case, when a correct quantity will pass into the gearbox by way of a hollow stud forming one of the anchorages for the chaincase. Thus the chain and plate clutch continually run in a bath of oil. The lubrication of the shock absorber is effected by a force-feed device, worked by the constantly meshing and revolving kick-starter pinions, which squeeze oil through special ducts and the hollow mainshaft to the desired point.

The plain barrel fork spring has been replaced by a device which eliminates the powerful rebound and so prevents breakage at this point. It has also been proved to have a very beneficial effect on front tyre wear.

The popular 4 h.p. engine remains unaltered. It is of 85 mm. bore and 97 mm. stroke, with side-by-side valves, operated by a single camwheel. A very efficient decompressor is provided, which greatly facilitates starting-up. The carburetter is of special design, and is of the two-lever pattern, although when on the road the air lever is opened fully and does not need touching, so that it may be truly called semi-automatic.



The Baby Triumph two-stroke, with handlebar control for the gears.



The new 4 h.p. chain-driven Triumph has an excellent shock absorber, and many other novel features.

The all-chain machine is called model SD, the other 4 h.p. machine being model H, and fitted with Sturmey-Archer three-speed gearbox and chain-cum-belt transmission, but otherwise identical with model SD.

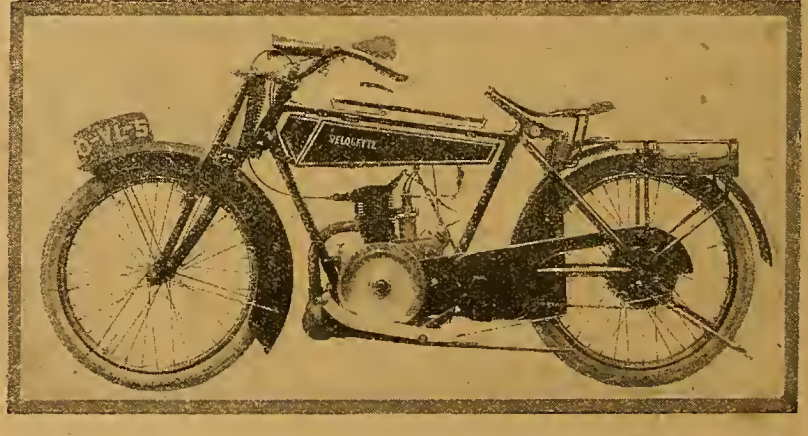
The Junior Triumph is a two-stroke lightweight of 64 mm. by 70 mm. bore and stroke, and 225 c.c. capacity. It is fitted with a simple two-speed gearbox controlled from the handlebar, and has no clutch or kick-starter. The wheels are 24 ins. by 2 ins., so that a very low saddle position is obtained, and the weight is only 125 lb. The frame is continued under the crankcase, and has a straight top tube, to which the round tank is attached by metal straps.

An annoying feature of many two-stroke machines—the noise made when the decompressor is operated—is eliminated on the Junior Triumph by providing a separate lead to the exhaust pipe from the compression release valve.

Stand No. 19.

Veloce, Ltd., Fleet Street, Birmingham.

MANY novelties are incorporated in the 1920 Veloce exhibited on this stand. First, particular attention should be paid to the simple yet efficient manner in which the engine is supported in the frame, the down tubes of which are duplex. The power unit itself is full



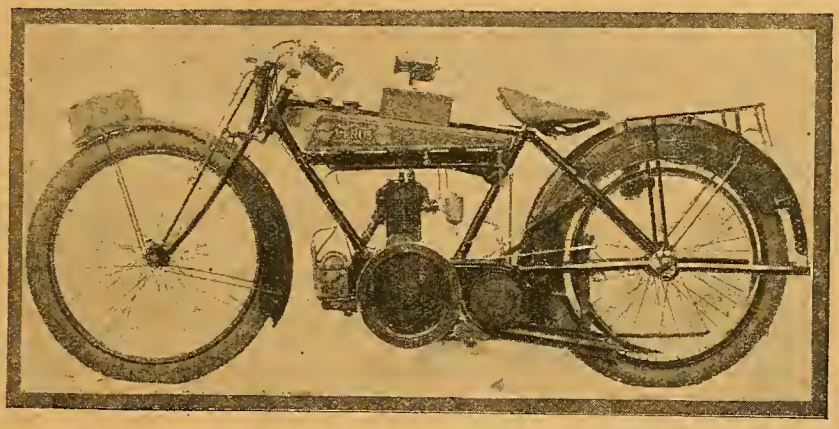
The two-stroke Velocette, which has a splendidly designed lubrication system.

The New Verus Models—A Heavy Sidecar Machine.

of appealing points, but space limits more than passing mention of the ample lengths of the main shaft bearings, the steel cylinder used in conjunction with an aluminium piston, and the unique crankshaft assembly. A new and entirely successful method of mechanical lubrication is utilized.

To turn to other features of the machine the gear change is noteworthy. The control is by means of a flat-shaped knob, which just fits the hand. The shaft to which this is attached passes through a bracket fitted to the top tube in a most get-at-able position, and the changing of the gears is obtained by partial rotation of the knob. The gear itself is a two-speed, although a three-speed box is being made.

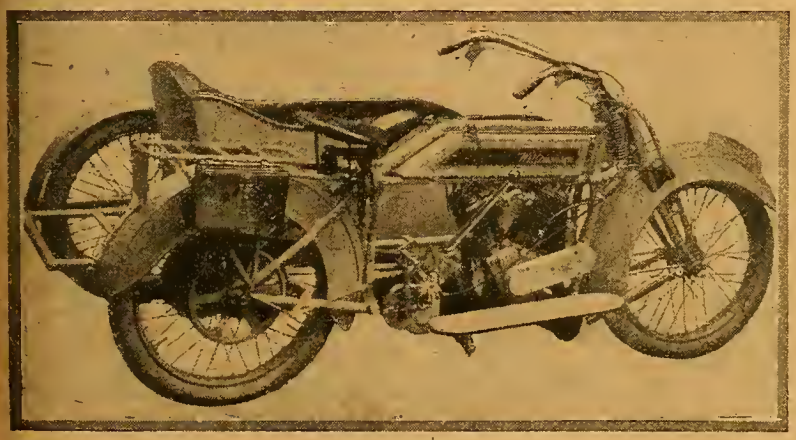
All workmanship throughout is unusually good, and the exhibit is worth the closest inspection.



The 4 h.p. Blackburne-engined Verus.

Stand No. 17a.
Wiseman, Alfred, Ltd., Glover Street, Birmingham.

FOUR very attractive Verus machines are to be seen on this stand. The single-speed 2¼ h.p. two-stroke model is to sell at a low figure, and will undoubtedly help to tap a huge market. The 2½ h.p. two-stroke with two-speed gearbox, kick-starter and chain-cum-belt drive is a good example of the modern light touring machine; it is priced at £75. A very interesting feature of these two models is the amount of work actually carried out on them by the makers. The cast-iron cylinder and piston and aluminium crankcase and footboards are cast by Messrs. Wiseman in their own foundry. The other two models are fitted with 2¾ h.p. and 4 h.p. Blackburne engines, the more powerful machine having a Sturmey three-speed gearbox. The colour scheme and lines of all models are very taking, a purple tank with gold lines being fitted. Attention to detail is very marked on these Verus machines. For example, the accessibility of the brake pedal, the strengthening of the tank, and the fitting of a small filter, as well as the usual filter gauzes, in the filler caps. These interesting machines were described in detail in our issue of October 29th.



The Williamson is ideal for sidecar work.

Stand No. 78.
Williamson Motor Co., Ltd., Earlsdon, Coventry.

THE Williamson Motor Co. are showing their 8 h.p. model, fitted with a well-tried water-cooled engine, harnessed to their sidecar, which shows many improvements for 1920. The water-cooled model has been with us for many seasons, and its general outlines will be known by those who follow the movement closely. It is fitted with an 8 h.p. water-cooled horizontally-opposed Douglas engine of 964 c.c., and Douglas three-speed gearbox, suitably strengthened for the additional horse-power. A Gallay honeycomb radiator is included in the design. Valves are horizontal and of large diameter, fitted with tappets which are easily removable. The company's duplex frame of great strength has shown up remarkably well in many competitions since 1913, and is too well known for a detailed description. It has a solid steel stamping ball head of a very substantial nature. Douglas forks of an extra heavy pattern are standard.

The tank has a petrol capacity of 2 gallons and ½ gallon of oil, which finds its way to the engine via a sight-feed semi-automatic lubricator fitted at the rear of the tank in a convenient position. The filler caps are 2⅛ in. diameter. It is finished in Ailsa grey with panel of royal blue edged with gold, and presents a very handsome appearance.

The carburetter is an Amac, and a B.L.I.C. magneto is used. The footboards are long and wide, carried on heavy cross tubes, the front pair being part of the frame and the rear pair secured to the bottom bracket.

The drive is all-chain, its cush drive being housed in the exceptionally large sprocket on the rear hub. Much attention has been paid to the mudguarding, and the front guard is a particularly thorough job. To the front wheel is fitted a front brake of conventional design; the rear one, however, is of the external-contracting pattern, having a drum 10 ins. in diameter, which should be capable of arresting the machine's progress on any hill where the surface is sufficiently good to provide a grip. The tyres are 700 mm. by 80 mm.

An innovation is the 6 h.p. air-cooled model, fitted with a J.A.P. V-twin engine and bottom bracket three-speed gearbox giving ratios of 5, 7, and 13 to 1 approximately. This model follows the general design of its bigger brother with a few detail alterations incidental to its construction. The frame has been suitably altered to accommodate the shorter limits of the engine plates. The magneto platform is carried on two short tubes of the frame, which supplies rigid and accessible adjustment to the magneto chain. Adjustment of the driving chain is on similar lines, the gearbox sliding along two tubes at the bottom bracket. The clutch on this model is handlebar-controlled, and the kick-starter mechanism is partly enclosed by the chain guard.

The Williamson sidecar for 1920 has been redesigned, and is now rather more roomy, with a shorter apex at the front. It is finished up to the usual Williamson standard, and the colours on the stand are eloquent of the firm's good taste. Some half-dozen sidecars are shown unattached, and a sidecar chassis alone is also exhibited. It will be noted that not a single bent tube is used in the chassis design, and the springing is of an exceptionally high order.

The Wolf Lightweights—The Unorthodox Wooler.

Stand No. 118.
Wulfruna Engineering Co., Ltd., Great Brickkiln Street, Wolverhampton.

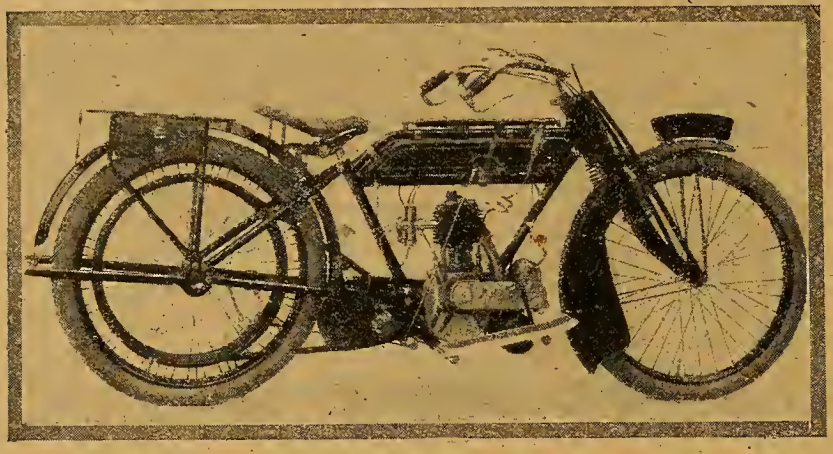
HERE are shown two exceedingly workmanlike lightweights, similar in design but differing as regards power unit, Model B having a Villiers two-stroke engine of 2½ h.p., while model C has a standard 2¾ h.p. J.A.P. engine.

Model B has an Albion two-speed gearbox of the constant mesh sliding dog type, while model C is fitted with a Burman gear, clutch and kick-starter.

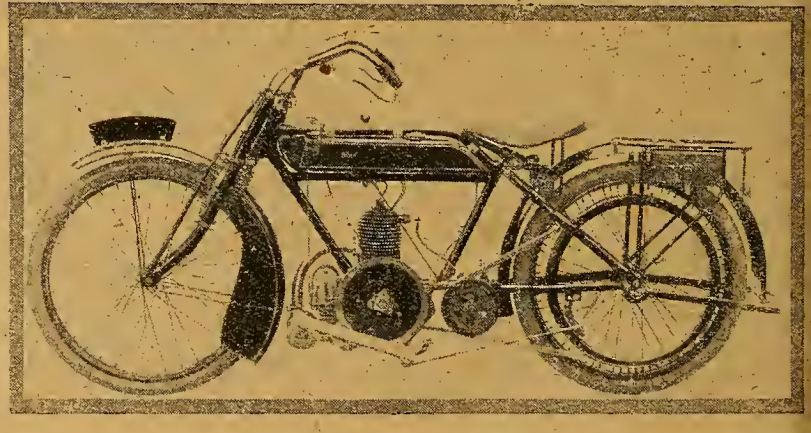
The carburetters on the machines displayed are A.M.A.C. lightweight models, but a Senspray can be supplied without extra cost to those who prefer it. Ignition is effected by an E.I.C., M.L. or O.A.V. magneto.

The frames are of exceptional strength, built up from weldless steel tubes, and are guaranteed to stand the worst Colonial roads. The spring forks are either the Druid or Brampton, the company being fully satisfied as to the merits of both forks. The wheels are 26 ins. by 2 ins., fitted with Dunlop studded tyres, and are amply mudguarded for the worst weather.

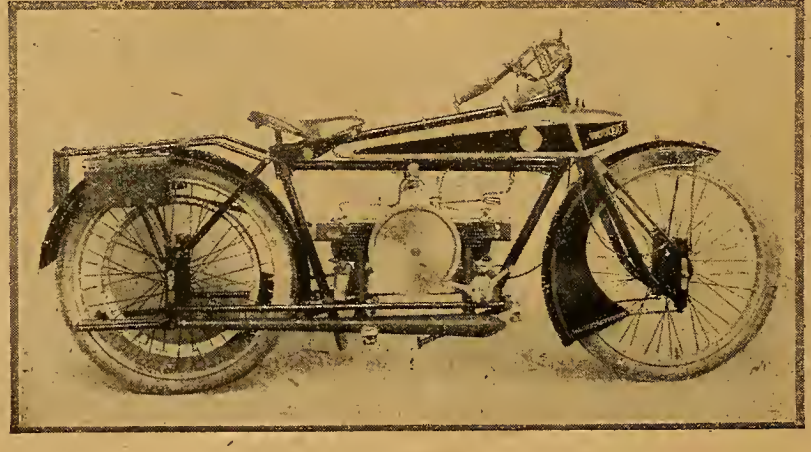
Model B with Albion gear costs £59 10s.; Model B with Sturmey-Archer or Burman and kick-starter, £65 10s.; Model C with Albion gear, £64; Model C with Sturmey-Archer or Burman and kick-starter, £70.



The Wolf is fitted either with two- or four-stroke engine. This model has the 2¾ h.p. J.A.P.—



—while this has a 2½ h.p. two-stroke Villiers.



The 2¾ h.p. Wooler has many original features and an unusual appearance.

Stand No. 47.
Wooler Engineering Co., Ltd., Alperton, London.

TWO models of the new horizontally-opposed 2¾ h.p. Wooler motorcycle are on show at this stand, the T.T. model which has dropped bars and foot rests, and the roadster with upturned bars and wide footboards.

A special working model is on view, which clearly indicates the action of the nine-speed variable pulley gear and the special lubrication system employed for the engine. As is well known, the principal features of the horizontally-opposed Wooler are its extreme accessibility and economy in running. The actual engine can be taken to pieces in the remarkable time of 6½ mins., which fact is demonstrated. Side exhaust valves are fitted and overhead inlet valves. The valve gear is self-oiling, owing to the valve tappet rods being hollow, and thus conducting an ample supply of oil to neat oil-tight chambers containing the valve rockers. The oil is raised from a sump beneath the engine by means of an endless chain elevator, which throws the oil into the timing gearcase. From here it drains through ducts to the crankcase, which is fitted with overflow pipes, thus ensuring a constant level. The lubrication of the cylinders and the bearings is effected by the splash method. A pedal on the right-hand side of the machine operates the gear. The pulley is under-geared and of large diameter.

A very satisfactory form of springing is incorporated, both wheel spindles being mounted on a system of springs giving a vertical movement. Each spindle passes through a pair of sliding pistons working in cylinders at the side of the wheel, coil springs being interposed above and below the pistons. No side play can possibly result from this method.

The road wheels are provided with hollow hubs and knock-out spindles and are consequently easily detachable. The front portion or nose of the tank forms a reserve petrol receptacle, which ensures the rider against any possibility of running short of petrol.

The present price of the Wooler is £85, and deliveries at the rate of 40 a week are anticipated.

The New Horizontal-Twin Zenith and its Brothers.

Stand No. 108.

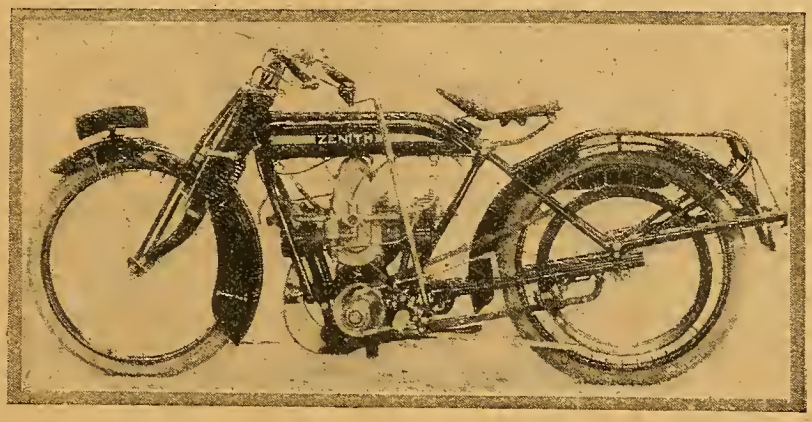
Zenith Motors, Ltd., Hampton Court.

ZENITHS are showing three types of machines—the 2¾ h.p. horizontally-opposed twin, the 5 h.p. sporting, and 8 h.p. passenger models. Of these, the first-named is naturally the centre of attraction.

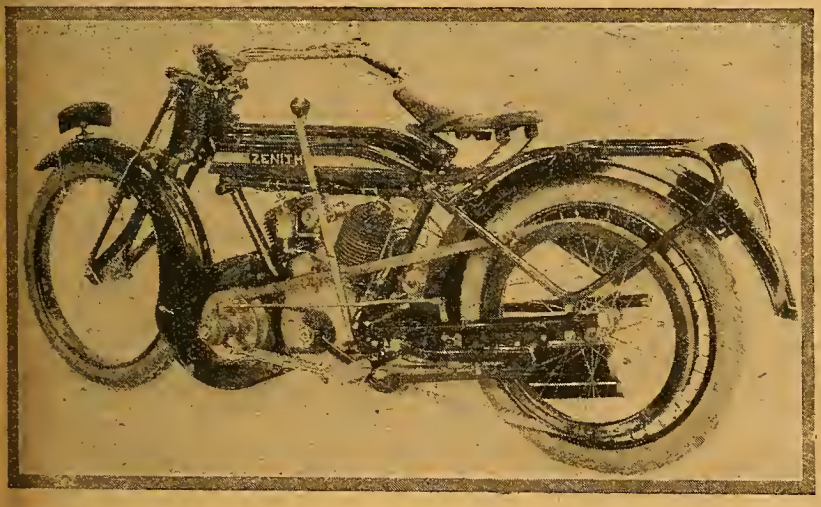
It has an engine with a bore and stroke of 58¼ by 65 mm. respectively, giving 347 c.c., fitted with an outside flywheel, side-by-side valves on top of the cylinders slightly inclined.

The drive is transmitted through a chain to a countershaft running on Skefko double row ball bearings, on the left hand end of which is fitted the well-known Gradua gear, which on this model gives a range of speeds from 5¼—1 to 11—1. The air release pipe is bent so as to discharge on to the driving chain, which, together with the Gradua gear, is well protected from mud by a large shield.

The frame embodies duplex front and rear down tubes, and is a successful attempt neatly to accommodate a type of engine notoriously difficult to house. This type of frame, in addition to possessing a symmetrical appearance, allows the cylinder to be detached without disturbing the crankcase. The rear stand is pivoted about 3½ ins. above the centre of the rear axle, with the idea of providing the extra leverage necessary for jacking up the machine easily.



This new Zenith model is the centre of many admiring crowds.



The 8 h.p. Zenith has a J.A.P. engine, and is intended for passenger work.

The saddle on all three models is mounted on quarter-elliptic springs, two supporting the rear, and one, with a roller end working in a groove, the peak. The old method of operating the back brake by means of a Bowden wire has been abandoned in favour of a system employing rods throughout. All models will have the back stays and carrier in one unit, immensely strong and easily detachable in case of accidental damage.

The 5 h.p. and 8 h.p. models are developments of similar machines marketed by the concern for many years past, and contain many detail refinements. The 5 h.p. has a J.A.P. engine of 70 mm. by 85 mm. bore and stroke, and is intended to be used as a sporting solo machine. It is direct driven through the Gradua gear, giving gear ratios of from 3½—1 to 7½—1.

The 8 h.p. Zenith is intended for passenger work, and is fitted with a J.A.P. engine of 85 mm. bore and 85 mm. stroke, driving by chain to a countershaft placed in front of the engine, incorporating a clutch and kick starter. Touring bars are fitted on this model.

An extremely large mudflap and undershield is a feature, protecting the chain and Gradua gear mechanism from the elements. The finish on all models is excellent, being black and grey.

Visitors to this stand will be interested in the many little detail improvements and departures from the orthodox, which a close inspection will reveal. As an instance of the latter, we would draw attention to the new pattern stand clip on the horizontally-opposed twin model, which does away with the ordinary method of attachment to the rear mudguard. On the two other types shown, the stand is fixed just behind the engine, and this position being almost the point of balance, the front wheel can be very easily lifted for cleaning.

It will be within the recollection of our readers that Zenith machines were very favourably commented on in the recent A.-C.U. trial on the score of silence.

The cylinder, camshaft and crankshaft assembly of the 2¾ h.p. Zenith engine.

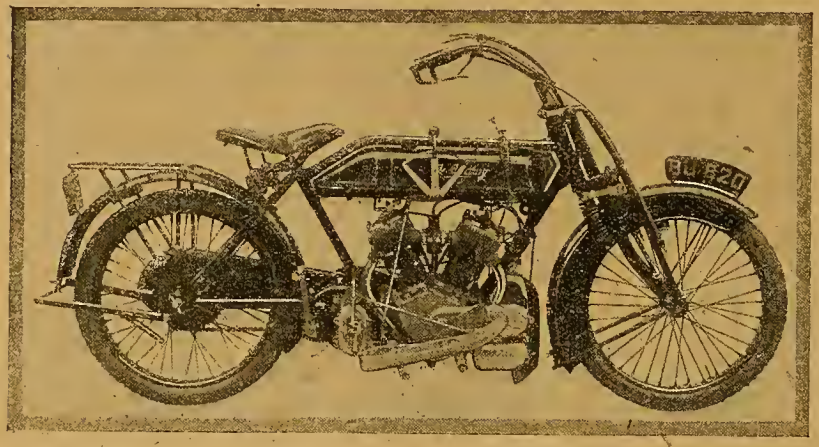
E51

LATE ARRIVALS AT OLYMPIA—The Kingsbury, Olympic, and Victoria.

Stand No. 1.
London and Midland Motors, Ltd., 445, Oxford Street, W. 1.

THE well-known Kingsbury scooter, with and without seat, and a new production in the form of the Kingsbury motorcycle are exhibited on this stand.

The Kingsbury scooter is fitted with a two-stroke engine developing 2¼ h.p. A particularly good feature is the position of the engine, which is placed neither over the back wheel nor over the front, but centrally in the frame, thus assuring good balance and stability. The drive is conveyed from the engine to a ball-bearing countershaft by chain, and thence by chain to the rear wheels. The wheels are disc and are fitted with 16 in. by 2⅜ in. tyres. The brakes are of the band type on the back wheel and are controlled by heel and Bowden lever. The price is 40 guineas, and a seat can be supplied for a small extra charge.



The 6 h.p. twin Bradbury which is described on page 117.

The Kingsbury Motorcycle.

THE Kingsbury motorcycle is fitted with a single-cylinder two-stroke engine with bore and stroke of 68 mm. by 70 mm., giving a cubic capacity of 254 c.c. High-speed white metal bearings are fitted to the big-end and main bearings of the crankshaft. A 9½-in. flywheel ensures steady running and an efficient silencer with tail pipe is fitted. The magneto is chain-driven and rapidly adjustable and Senspray or A.M.A.C. carburetters are optional. Transmission is all-chain, through a two-speed gearbox fitted at countershaft and a special cushioning device to absorb engine shocks. The spring forks are of Kingsbury design, and two pairs of footrests are fitted as standard. The tank tapers from front to rear and has a capacity of 1½ gallon petrol and 1 quart of oil, semi-automatic sight-feed lubrication being employed.

One of the most interesting features of all is, however, the price, which, at £50 only, comes several pounds below the majority of motorcycles of this type. Deliveries are expected shortly after the Show.

£50

Stand No. 123.
Olympic Cycle and Motor Co., Ltd., Granville Street, Wolverhampton.

LIGHTWEIGHT enthusiasts should not pass this stand without an examination of the 2½ h.p. Olympic. Perhaps its most original feature is the frame, which has a patented design of gearbox suspension, adaptable to any make of gearbox, providing positive, simple, and instant adjustment to the chain portion of the transmission by merely turning a conveniently-placed bolt.

The gearbox, during the process of chain adjustment, can swing for a limited distance around the forward bolt, and thus provides an arc of travel more than equal to a whole link in the length of chain, therefore, it should not be necessary to carry half links in the tool kit, as the entire process takes only a matter of seconds.

Straight tubes only are used in the frame construction, the rear as well as the head being reinforced with a web. The bridge for the rear mudguard is exceptionally strong, and permits of very wide guards being used where necessary. The stand support is also ingenious, having two flat surfaces in contact when in operation.

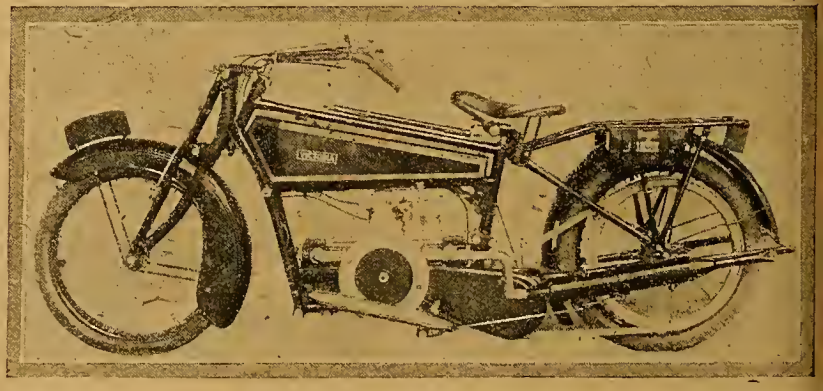
The gearbox on the model shown is a Burman two-speed, with kick-starter and hand-controlled clutch. The power unit is a Verus of 2½ h.p., its dimensions being 70 mm. by 70 mm., and its capacity 296 c.c. It is of the three-port type, and has clean, tapering fins to its cylinder, while the sparking plug placed at an angle of 40 degrees requires the shortest possible high-tension wire.

The wheels are 26 by 2¼, and are fitted with Red Streak tyres and all black hubs.

Stand No. 87.
Victoria Motor and Cycle Co., Ltd., Dennistoun, Glasgow.

The exhibits on this stand consist of Victoria motorcycles, and attention is directed principally to the 5-7 h.p. horizontally-opposed twin model. A Coventry Victor engine, with outside flywheel, forms the power unit, and this is supplied with gas from a single-lever Amac carburetter fixed in an unusual position above the induction pipe. Full details of this engine will be found in the engine section of this issue.

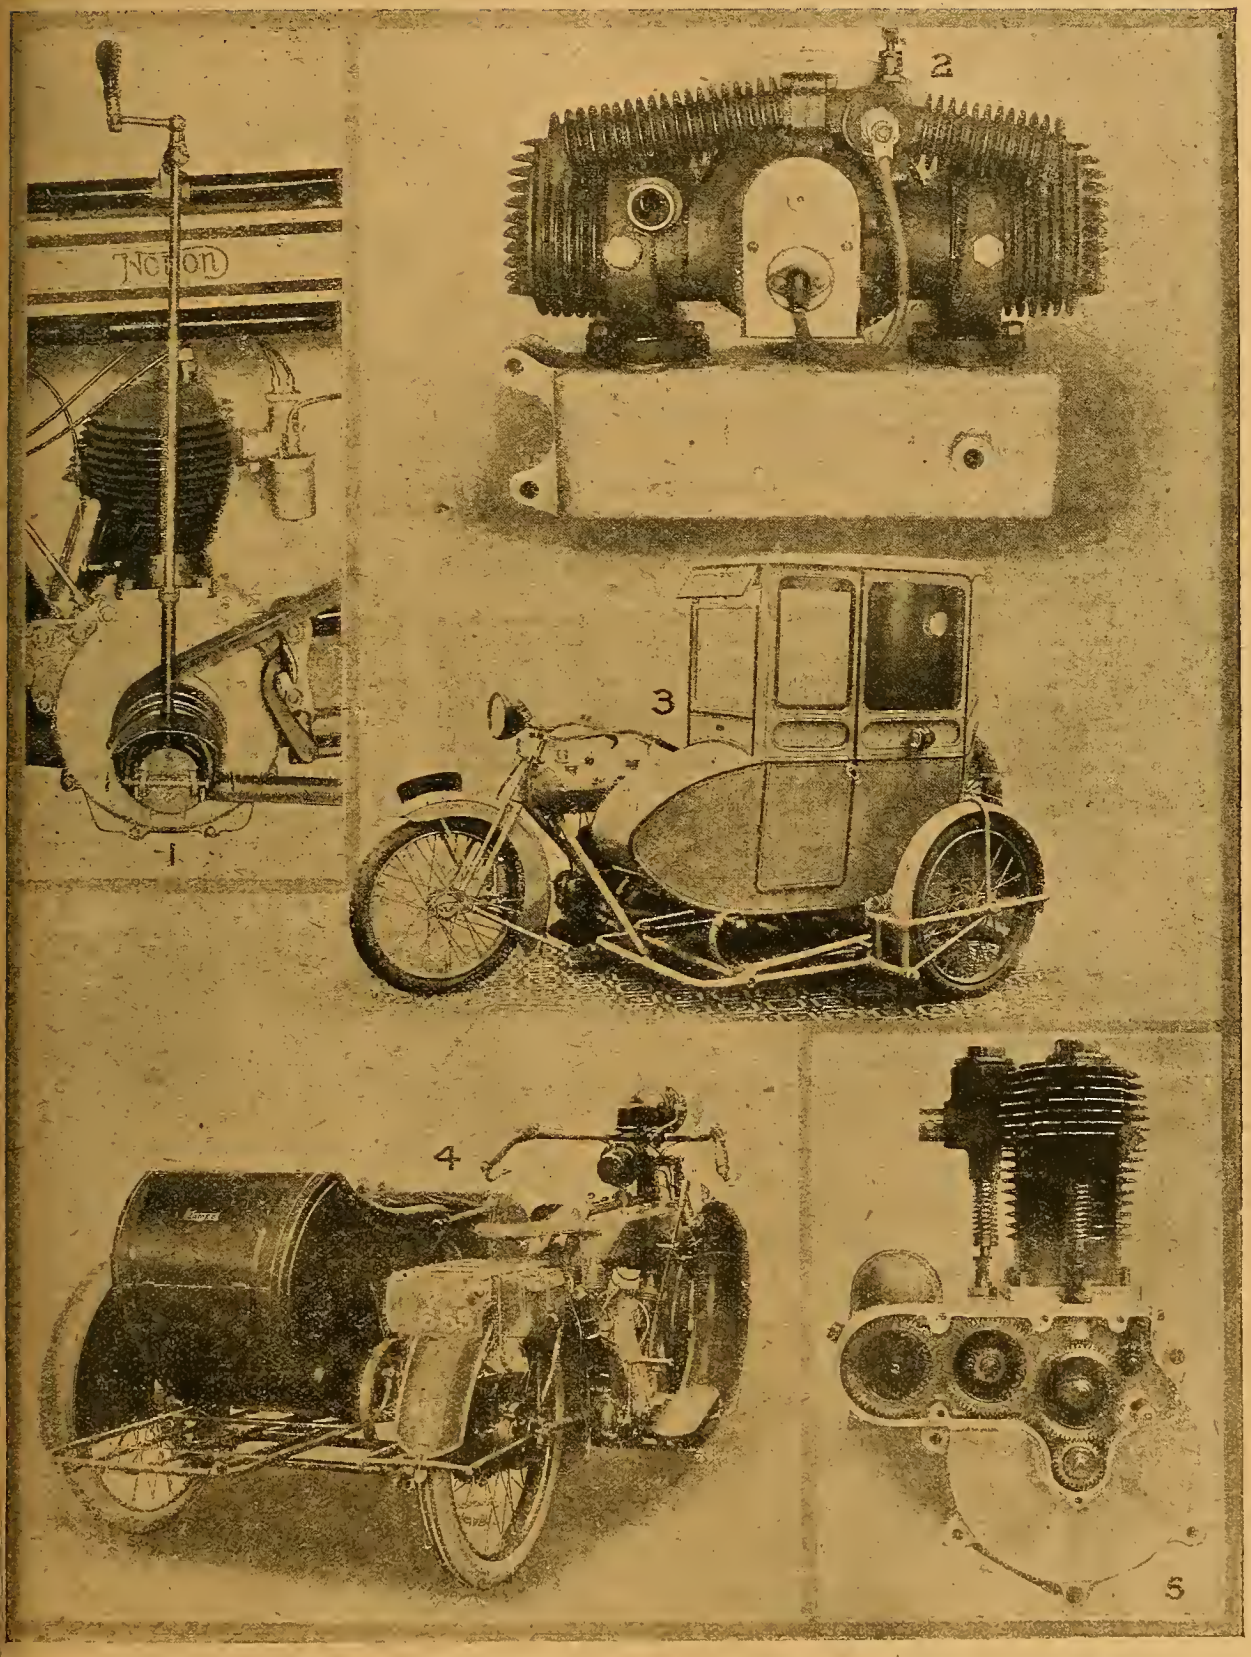
The frame has a sloping top rail, thus allowing a low saddle and a lengthy wheelbase. Duplex front down tubes support the parallel stays which form the engine cradle, and Brampton forks are fitted, with the usual rim brake. A three-speed Sturmey-Archer gearbox is located at the countershaft, with kick starter and handlebar-controlled clutch. Chain-cum-belt transmission is employed. A noticeable point is the large silencer, which is attached to the near-side chain stay. The gas enters it from the engine by a single exhaust pipe with two right-angled bends, and reaches the atmosphere by a short fish-tailed pipe. The petrol tank is of good capacity, and lubrication is by hand pump. The machine is finished in black, with gold-lined tank.



The 1920 Victoria is a horizontal twin with Coventry Victor engine and countershaft gear. Note the novel silencer design.

Another Victoria model is the 2½ h.p. two-stroke lightweight, which has a Villiers engine. Three types of this model are made, one a fixed gear, another having a two-speed countershaft gear, and the third a similar gearbox with clutch and kick starter.

INTERESTING EXHIBITS AT THE SHOW.



1. The Bradbury gear fitted to the speed model Norton. 2. The horizontally opposed twin engine of the Black Prince. 3, Studying the lady passenger's comfort—the Bat cabriolet. 4. A rear view of the handsome James combination. 5. The Quadrant engine showing the unusual valve position.

LATE ARRIVALS (contd.)—Private Shows.

Stand No. 230.
Midland Gear Case Co.

A LARGE selection of leather goods of interest to motorcyclists is shown on this stand, including leg shields and tool bags. The leather knee-grips for fitting to the tank are worth examination.

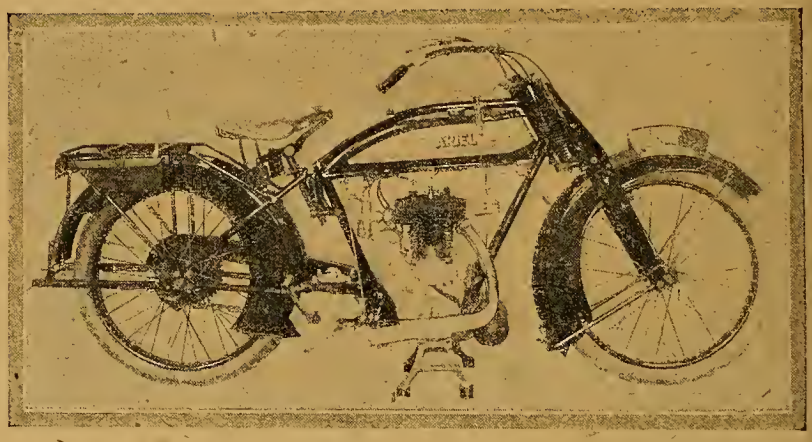
Stand No. 174.
Perry and Co., Ltd., Tyseley, Birmingham.

ALTHOUGH the majority of exhibits on this stand are of pedal cycle goods, there are one or two items that are of interest to motorcyclists. Two sizes of chains are made, viz., $\frac{5}{8}$ in. by $\frac{1}{4}$ in. and $\frac{5}{8}$ in. by $\frac{3}{8}$ in. Free wheels for motorcycles are also made in two types, for 20-tooth and 22-tooth sprockets. All the articles are well up to the Perry standard of manufacture and finish.

Stand No. 228.
British Lighting and Ignition Co., Ltd., B.L.I.C. Works, Cheston Road, Aston, Birmingham.

THE B.L.I.C. magnetos are well known, and six models of this instrument are shown, the ZA1 for small single-cylinder engines, the ZE1 for large singles, the ZEV for twin-cylinder engines, the ZE2 for horizontally-opposed engines, the ZA2, a similar model for Bowden control, and the ZA4 for four-cylinder motorcycle engines.

In design and construction the B.L.I.C. magnetos are particularly sound, as may be seen from the many component parts on view. Armatures, carbon brush holders, distributors, contact breakers, and other component parts are all on view.



An entirely new Ariel, the 4½ h.p. single with chain drive, new forks and redesigned frame.

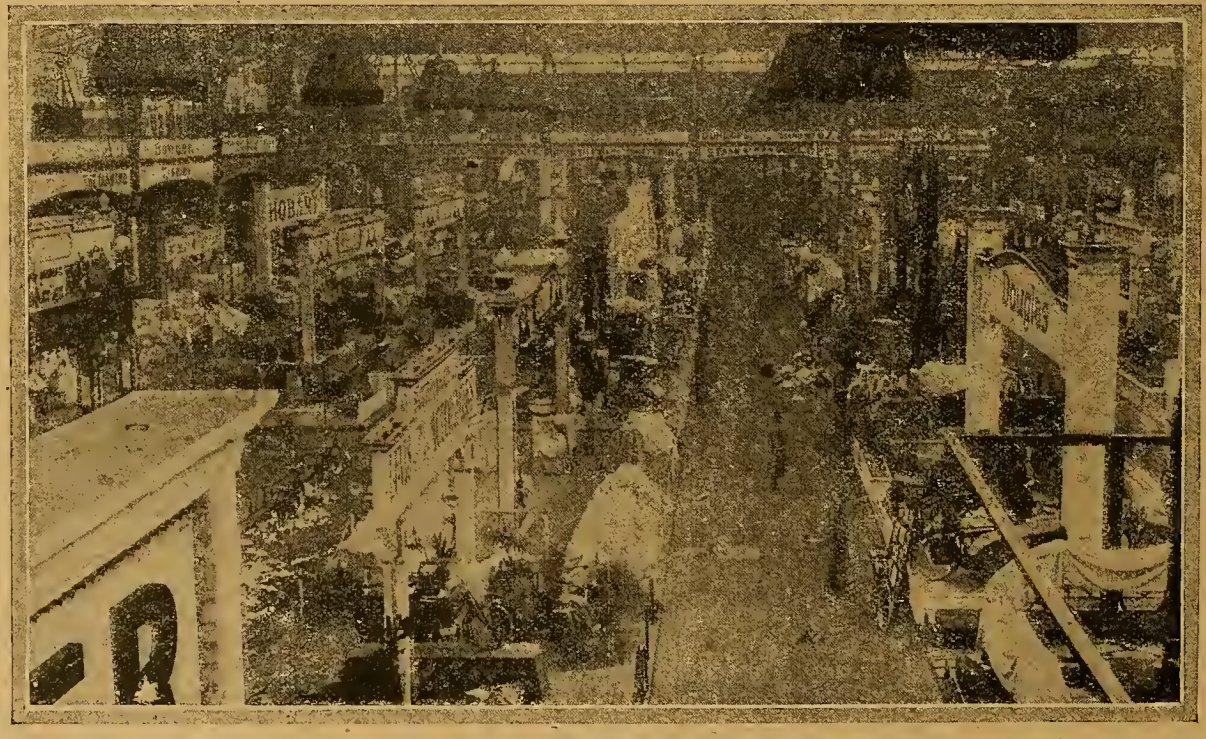
Stand No. 13.
The Red Streak Tyre Co., 62, Basinghall Street, London, E.C. 2.

THE motorcycle tyres here shown have a tread of the finest red rubber, the wearing qualities of which have been demonstrated during past seasons, while the walls are of tough white rubber. This combination is claimed to have a life unattained by any other pattern, and is expected to appeal to hard riders who grudge time spent on changing covers. Both ribbed and studded treads are on view. Another exhibit, costing a little less, is their No. 6 studded cover of the same high-grade materials as the former, but all grey on conventional lines.

Crowded Out.

MESSRS. Burney and Blackburne have been unfortunate enough to be crowded out. At their Shaftesbury Avenue showrooms a full range of their productions is on view, and they cordially invite all motorcyclists to pay them a visit.

MESSRS. Pearson and Sopwith, the makers of the P. and S. motorcycle, have also been crowded out. It will be remembered that the P. and S. was recently described in *Motor Cycling*. Messrs. Pearson and Sopwith are holding a special show at their showrooms at 60, Mortimer Street, London, W.,—to which all interested are invited.



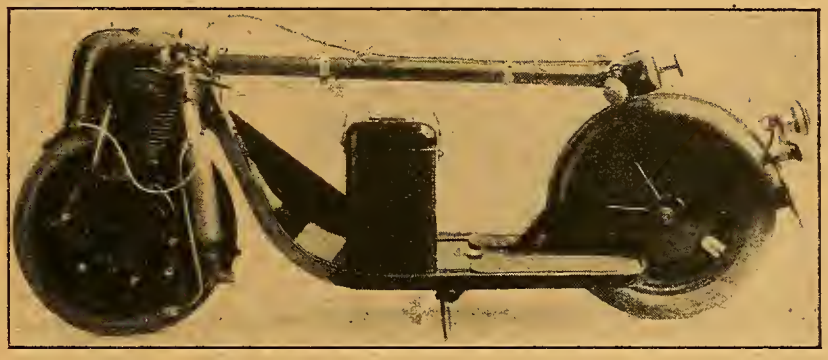
What Olympia looked like just before the opening. Last minute preparations in progress.

OF INTEREST TO LADIES, CYCLISTS, AND SCOOTER RIDERS.

SECTION 2.—Scooters and Lightweight Sets.

Stand No. 28.
W.T.T. Eng. Co., Ltd., 6-10, Dalling Road, Hammersmith, London, W.

THE Autoped scooter and the British Johnson Motor Wheel attachment for bicycles are exhibited here. The Autoped scooter is controlled principally by the steering column. Pushing the steering column forward engages the clutch, and when pulled right back the brake is put on. Twist-grip control is fitted for the throttle, and large diameter tyres are used. The complete weight of the machine is somewhere in the neighbourhood of 100 lb. The steering column can be folded down to form a handle for carrying, and consequently the machine can be stored in almost any small space. The Johnson Motor Wheel consists of a small twin-opposed engine, which is complete with a magneto and electric lighting generator fitted into the flywheel. It will propel an ordinary cycle at the rate of 35 m.p.h., and is capable of 150 m.p.g.



The Autoped scooter, shown on the W.T.T. Engineering Co.'s stand.

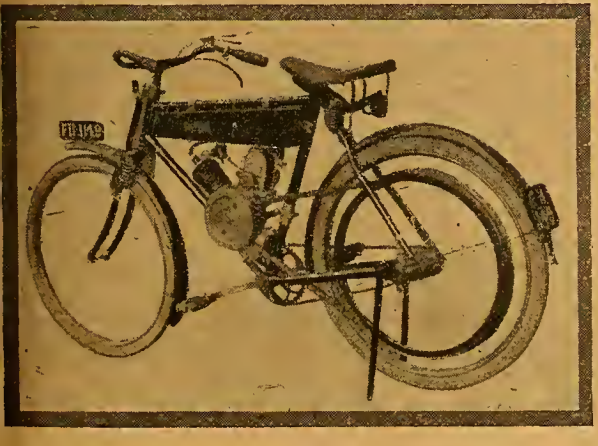
Stand No. 40.
Chas. Day Manufacturing Co., Ltd., 221-222, Shoreditch, London, E. 1.

THE only item likely to be of interest to motorcyclists at this stand is the Dayton motor-driven invalid tricar. This has been designed to meet the needs of the disabled. The power unit employed is the Dayton two-stroke engine, and the transmission is effected by chain and belt. The engine is geared down to give a maximum speed of 8 m.p.h., and the steering is by a lever operating on a ratchet. The petrol consumption is very low, being approximately 75 m.p.g., consequently the running cost is very small. The price is 80 guineas.

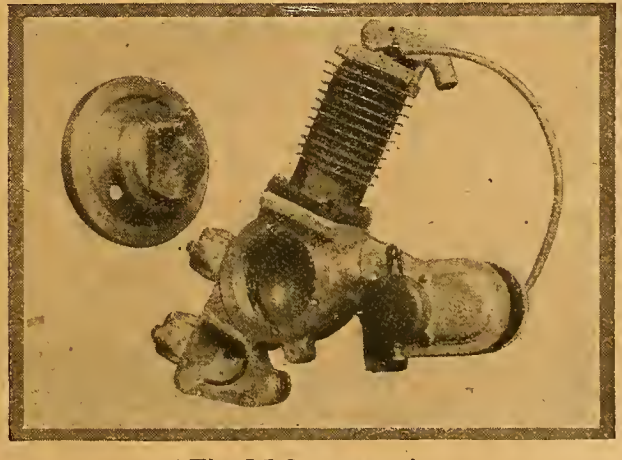
Stand No. 39.
J.E.S. Motor Works, Worcester Street, Gloucester.

LIGHTWEIGHT motorcycle enthusiasts will find plenty of interest in the latest 1½ h.p. J.E.S. attachment and motorcyclette, on view at Stand No. 39.

The J.E.S. is exhibited both as a separate auxiliary motor attachment ready for fitting to an ordinary cycle, priced at 23 guineas, and in the complete form with special cycle, engine, tank, etc., at 38 guineas. The 1919-20 model contains many improvements over the previous models. An interesting new feature is the patent single-lever floatless carburet-



The J.E.S. motorcyclette.



The J.E.S. power unit.

The Simplex-engined Motorped—Commercial Skootamotas.

ter, which is claimed to give 200 m.p.g. on a gearing of 8 to 1. The inlet valve is mechanically operated by a lever situated in the inlet pipe. An oil sump, containing a quantity of oil sufficient for nearly 300 miles, and incorporating a mechanical oil pump, is a feature of the latest model. The engine has a bore and stroke of $2\frac{3}{16}$ ins. by $2\frac{3}{8}$ ins. respectively, and develops a full $1\frac{1}{2}$ h.p. An aluminium piston is incorporated, and the gudgeon pin floats in the piston, instead of in the connecting rod, as is usual. A new method of cooling and oiling the gudgeon pin is embodied.

Stand No. 36.
Patrick Engineering Co., Ltd., New Summer Street, Birmingham.

AT the present time anything which offers a prospect of providing cheap motor cycling for the million attracts unbounded interest. The Motorped cycles exhibited on this stand form a link between the bicycle and the lightweight motorcycle. The machine is an ordinary bicycle fitted with a Simplex power unit, and this was described at considerable length in our issue of September 17th, 1919. Briefly, a self-contained power unit, consisting of a 1 h.p. two-stroke engine with magneto ignition and clutch, is carried by suitable stays over the rear wheel, which it drives through an additional chain sprocket and roller chain. The tiny power unit is remarkable for the neatness of design and economy of space. The unit can be obtained separately for attachment to any machine; it weighs 22 lb. and costs £24 3s.

The Skootamota, made by Gilbert Campling, Ltd. Commercial Scooters are also on view.

Stand No. 41.
Campling, Gilbert, Ltd., 1, Albemarle Street, London, W. 1.

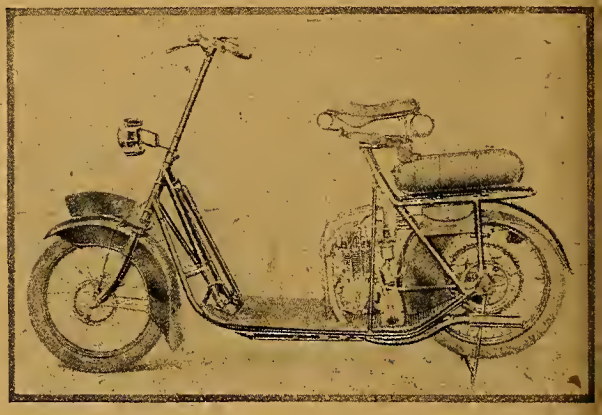
THE A.B.C. Skootamota is the only exhibit at this stand. Two commercial types are shown, having a box for parcels fitted in place of the usual seat. A spring saddle being attached direct to the top of this. A tropical model is also shown, enamelled in light colours, and fitted with a canopy. Three standard models are exhibited, one of which is nickel-plated all over. As is well known, this scooter is fitted with a small four-stroke engine of 124 c.c. The cylinder is placed horizontally over the back wheel, and is fitted with a detachable head, while the transmission is direct by chain to the back wheel. The valves are both located in the head, the inlet valve being at the side and the exhaust valve overhead. The power is transmitted through the camshaft, which allows of a sufficiently low gear being obtained without the use of sprockets of undue size, the wheels being 16 ins. by $2\frac{1}{2}$ ins.

Stand No. 17.
T. and T. Mtr., Ltd., 52a, Condnit Street, London, W. 1.

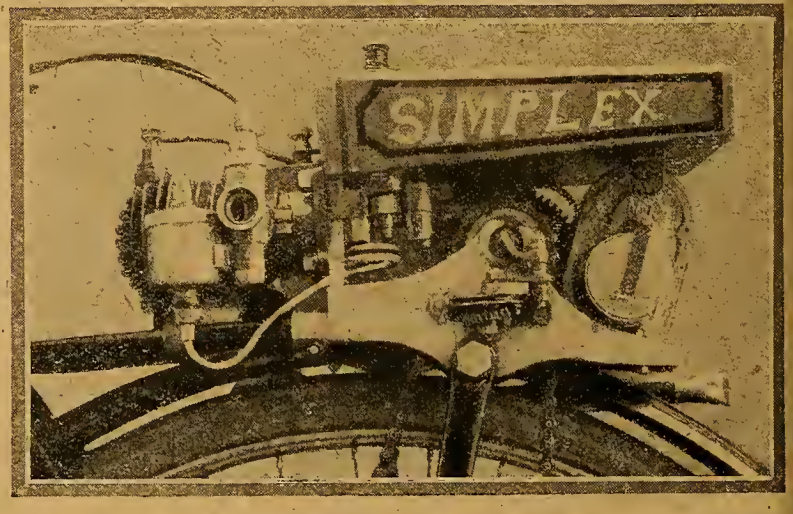
THE Silva scooter is shown at this stand. It is fitted with a modified Auto-Wheel power unit, the small road wheel of which forms the front wheel of the scooter. The footboard is mounted on springs and covered with rubber corrugated matting. The rear wheel is 12 ins. in diameter and fitted with 300 mm. by 60 mm. special Palmer tyres. A working model of the engine in section is also on view. The present price is £55, or with a seat £56.

Stand No. 1a.
Sumner, Vaughan and Co., 28, Victoria Street, Westminster, S.W. 1.

TWO models of the Whippet motor scooter, together with one of the power units employed, are shown on this stand. The scooter is a well-made article, the frame is of the duplex type, and the engine, a four-stroke of $1\frac{1}{2}$ h.p., is built on advanced aero lines. The transmission is effected by a roller chain from the engine to a countershaft, and from thence to the rear wheel. Both chains are easily adjustable, and a shock absorber is incorporated. The wheels are quickly detachable, and are fitted with 18 in. by 2 in. Palmer cord tyres. Internal-expanding brakes are fitted to both wheels, the rear being foot-operated and the front by handlebar grip. The machine is equipped with a Runbaken magneto, Amac carburetter, and the price, which includes free registration and one year's free insurance against all risks, is 47 guineas. The Whippet should not be missed.



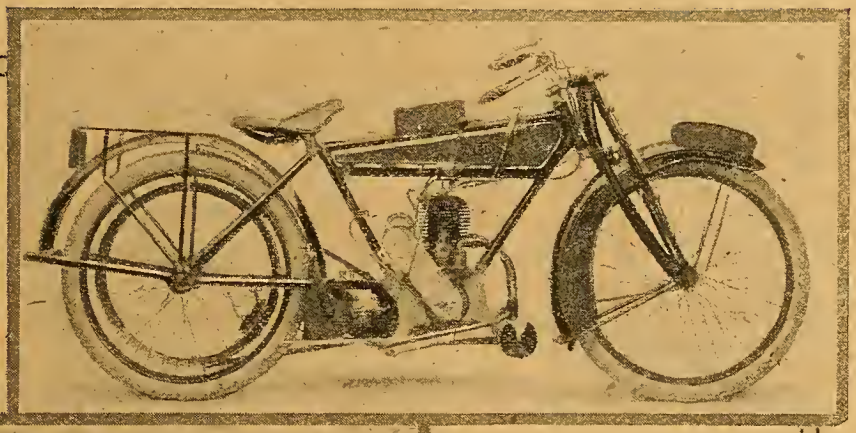
The Whippet scooter of $1\frac{1}{2}$ h.p.

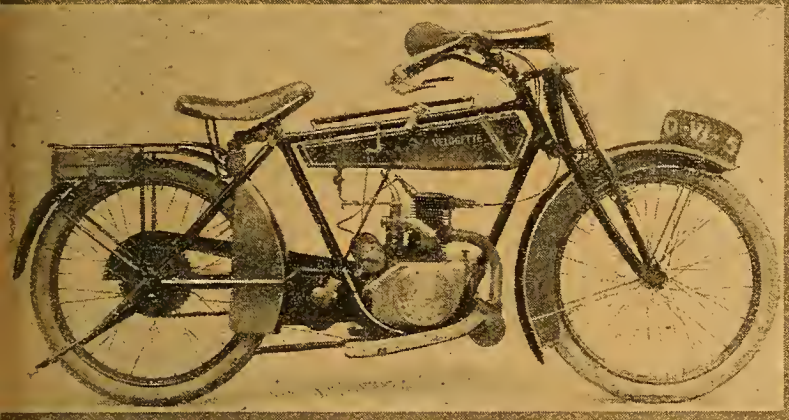


The Simplex power unit, which is placed over the back wheel of the Motorped.

TYPICAL TWO-STROKE LIGHTWEIGHTS.

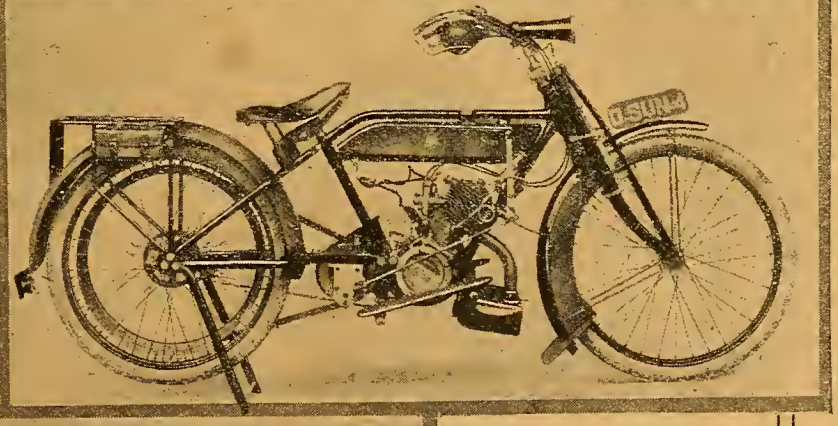
The Verus which is equipped with a 2½ h.p. two-stroke engine, Brampton forks and Burman two-speed gear.

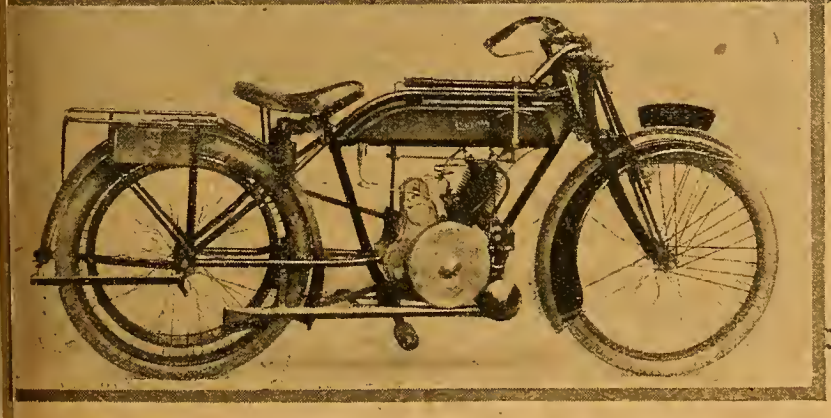




The Velocette, one of the few all-chain driven lightweights, incorporates an automatic lubrication system. The two-stroke engine has many novel and ingenious features.

The Sun two-stroke is fitted with a two-stroke engine of efficient and simple design. The crankcase is a one piece casting.





The Clyno two-stroke, a well made lightweight, in which the engine and gearbox form one unit.

SECTION 3—SIDECARS.—Mills-Fulford—Grindlay.

Stand No. 53.
Mills-Fulford, Ltd., Crown Works, Coventry.

EVER since we have had sidecars, the above names have been inseparably associated with the movement. We therefore looked for something of exceeding merit, and can honestly say we found it. The De Luxe model is a sidecar of exceptionally fine construction. The body is somewhat on the lines of this concern's very successful Empress model of a few seasons ago, but is roomier and has a larger chassis. This latter has a special double frame, and one might almost describe it as one chassis superimposed upon another. Deep springs in the back and seat, in combination with the large Cee springs of the chassis, insulate the passenger from road shocks. The luggage grid is quite novel; when not in use it is stowed out of sight in the back of the sidecar, and is hinged and merely let down when it is desired to carry luggage. This device does not interfere with the seat locker. This model has been introduced to meet the desires of big-twin enthusiasts, such as riders of Harleys, Indians, Zeniths, etc.

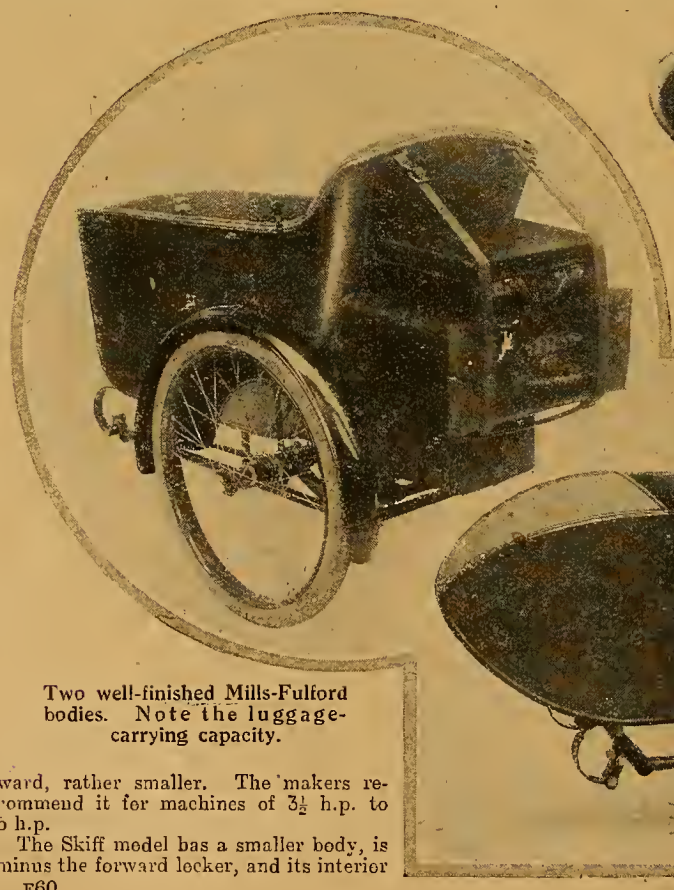
Four samples each of the Corvette and Skiff are shown. The first, which has been with us for eight years, was supplied to nearly all the Allies during the period 1914 to 1918. The body is roomy and thoroughly well upholstered. It has a locker under the seat and another forward, rather smaller. The makers recommend it for machines of 3½ h.p. to 6 h.p.

The Skiff model has a smaller body, is minus the forward locker, and its interior is not quite so well appointed as the car just described. It is intended for machines of low horse-power, where weight is a consideration, and is an excellent compromise between luxury and lightness. The Corvette costs £25 5s. and the Skiff £23. An Olympian Corvette, a larger model, is also shown for £26 5s., but deliveries do not commence until April next.

The Family model has an additional seat for a child and removable screen, and costs 28 guineas. It has also four points of attachment, while the above models have only three, although any model not so fitted can have a fourth attachment for an additional 30s.

The Double Purpose model should not be missed. While principally a tradesman's sidecar, it has a comfortable seat and upholstered back, and can be used for the conveyance of goods or persons. It is constructed of wicker, and in common with the rest of the exhibits here, is well finished. The price is £23.

Screens and hoods are shown, the former at £3 5s. and the latter at £4 4s. A new luggage grid and petrol can holder are two other interesting items on view.

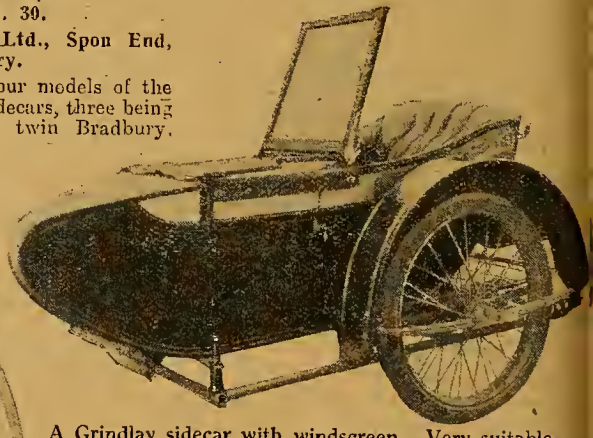


Two well-finished Mills-Fulford bodies. Note the luggage-carrying capacity.

Stand No. 30.
Grindlay (Coventry), Ltd., Spon End, Coventry.

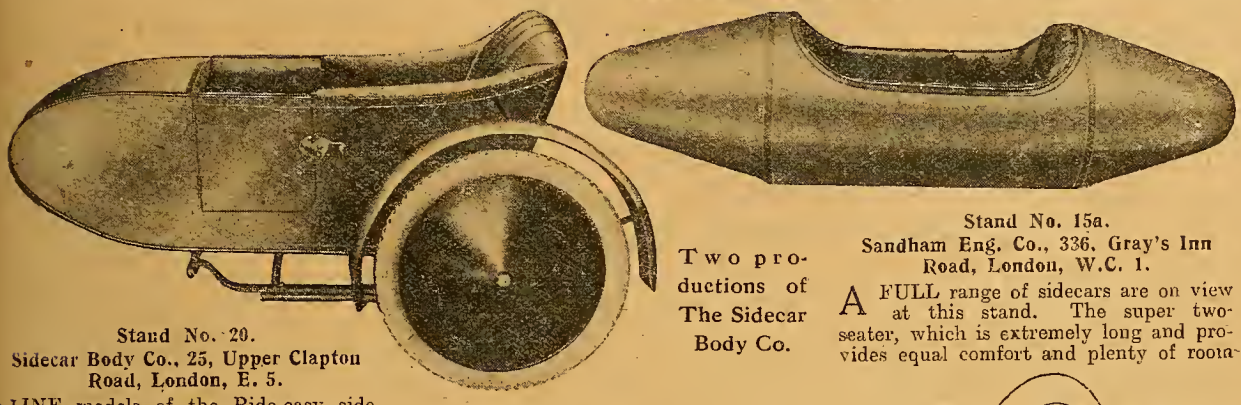
ON this stand are four models of the double-sprung sidecars, three being attached to Triumph, twin Bradbury, and Harley-Davidson motorcycles and one unattached. The 1920 models have their new windscreen (protected), which is adjustable to any position and makes allowance for the accommodation of a second passenger. This model has a new form of luggage grid and petrol-can holder on very novel lines. The chassis of a patented design is constructed of weldless tubing with not a single bent tube. The wheel is sprung with half elliptic springs shackled at rear ends. It boasts a very substantial mudguard 7 ins. wide with side valance. This is fixed to body and not to wheel, thus getting the benefit of the whole system of springing.

The body is of exceptionally roomy proportions, of handsome appearance, soundly upholstered, on cantilever springs (patented system). The front panel is of aluminium. In addition to the locker under the seat, a small one is provided in the dash. This model sells at £33 (approximately), hood, screen, luggage grid and petrol-can holder being obtainable at extra cost. The additional cost of a 28 in. wheel instead of 26 in., making the sidecar suitable for American machines, is £2. Purchasers have the choice between Dunlop and Palmer tyres.



A Grindlay sidecar with windscreen. Very suitable for Harley-Davidsons.

Sidecars for all Purposes—A Spring Wheel Suspension.



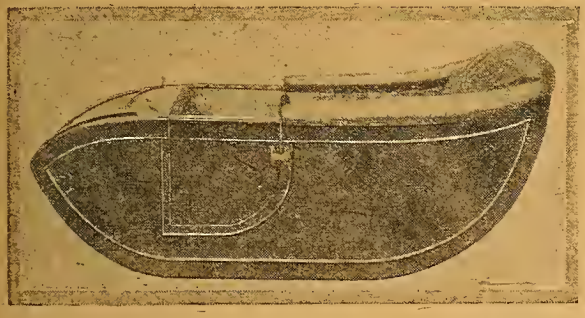
Two productions of The Sidecar Body Co.

Stand No. 20.
Sidecar Body Co., 25, Upper Clapton Road, London, E. 5.

NINE models of the Ride-easy sidecar bodies and chassis constitute the programme of this concern for 1920. The standard body has a very neat underslung chassis, which is beautifully finished and well sprung. A novelty is the projectile super-sporting body, which is made of aluminium to the exact shape of a shell. The nose, which is polished, is spun out of one piece of aluminium. To give it a realistic effect, copper bands are fitted to the side. Although strongly built, this sidecar is very light and comfortable and has ample locker room.

much on the lines of the boot of a car. The tourist will be particularly attracted by this, as there is also room for more luggage on the lid of the locker. The comfort of the passenger is assured by the springing system, which is by coil buffer springs at the front and by large three-leaved C springs at the rear, additional coil springs also being used for a very heavy body. On both models the upholstery is carried out in the best leather cloth with spring cushion and back.

The R34 is designed for the sporting



A smart sidecar body by Birch Aircraft described on page 167.

Stand No. 25.
Watsonian Folding Sidecar Co., Ltd., 129-131, Conybere Street, Birmingham.

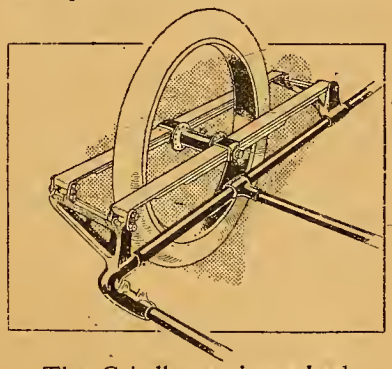
WATSONIAN sidecars are well known for their comfort and sporting appearance, and the chief interest on this stand centres round the new chassis known as model U and the two new bodies known as the Monarch and R34 or Zeppelin. The chassis is triangulated and gives the greatest strength for the weight. It has four-point attachment and is suitable for machines of 4 h.p. and upwards, being capable of resisting the severest stresses occasioned by bad roads or a powerful machine.

The axle is very strong and is of the best steel reinforced by double D-section tubes. The wheel is built on an extra wide hub, designed to exclude dust and grit and retain oil. The mudguard is intended to be fitted to the bodywork, and is of large size and dome-shaped. The two bodies are both on sporting lines, and great attention has been given to wind resistance.

On the Monarch there is a large luggage locker in the tail, formed very rider, and, as its name suggests, it is cigar-shaped. A locker is arranged behind the seat, the back of which hinges forward to give access to it. The standard colour is Watsonian blue, and so finished the appearance of both models is very attractive.

Stand No. 15a.
Sandham Eng. Co., 336, Gray's Inn Road, London, W.C. 1.

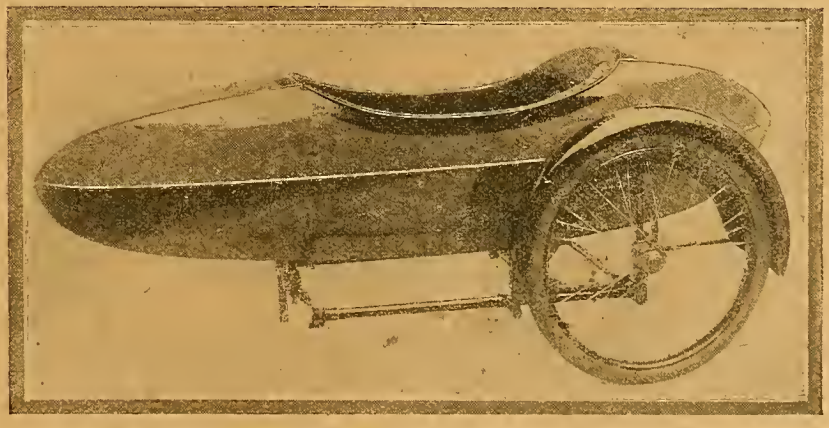
A FULL range of sidecars are on view at this stand. The super two-seater, which is extremely long and provides equal comfort and plenty of room



The Grindlay spring wheel suspension.

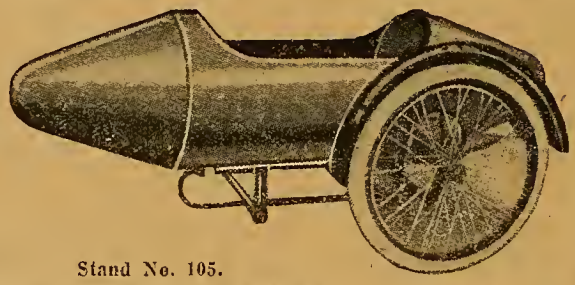
for two passengers, is fitted with a double springing system at the back, and is priced at £32 10s. The model Elite is designed to give the greatest possible comfort. A novelty is the upholstery at the back, which is shaped so as to fit the back of the passenger. The sidecar has a bulbous back, and a very large luggage compartment, the price is £26.

The model de luxe is a well-equipped sidecar provided with hood and screen, and is very suitable for all-round touring purposes. It is priced at £22 10s. A sporting outfit suitable for Indian spring frame machines with an all-metal body costs £22 10s. A novelty is the single or two-seater body. The upper part of the nose can be lifted out, and, being upholstered underneath, forms the second seat, a folding back being provided.

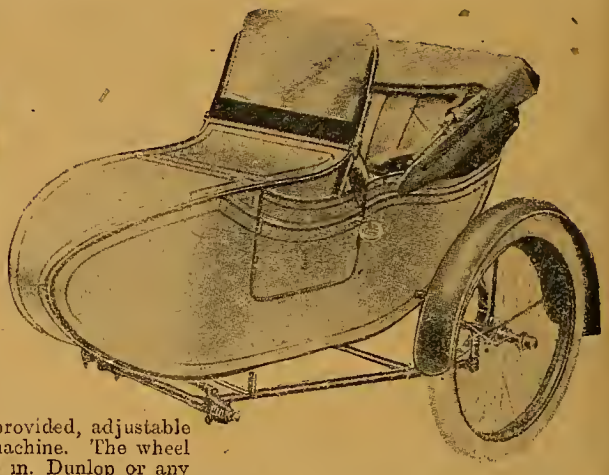


An attractive Watsonian sidecar, known as the R34.

Various Types of Montgomery Sidecars—The Luxurious Henderson.



For the speedman: the Sandum sporting body.

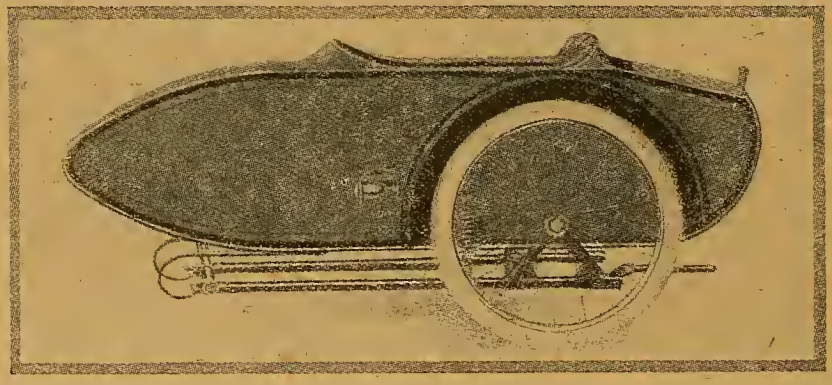


One of the latest types of Montgomery sidecars.

Stand No. 105.
Montgomery, W., and Co., Lower Ford Street, Coventry.

ONE of the pioneers of the sidecar movement was the Montgomery Co., and that it is still keeping in the front rank is evinced by the three excellent models to be seen on this stand. A few improvements are noticeable over the previous productions, one being that by a new back attachment the sidecar axle may be brought parallel with the ground, irrespective of the varying tyre or wheel sizes. Another is the new design luggage-grid and petrol-can carrier, which is fitted as an extra. Yet a third is found in the new method of upholstery springing and hinged seat.

As to the actual models shown, No. 1 is the most luxurious, and possesses a handsome coach-built body, finished to order in either green, grey, buff or black, suspended by leaf-springs on an underslung weldless steel tube chassis. Four-point attachment is provided, adjustable to fit any make of machine. The wheel is 26 ins., with a 2⅞ in. Dunlop or any other best make of tyre to order, amply mudguarded by a 5 in. blade with inside valance, firmly anchored to prevent rattle. The length of the body is 60 ins., and the weight of the complete sidecar is 136 lb. A locker is provided under the seat.



The handsome body and straight-tubed chassis of the Henderson sidecar.

Model No. 2 has a similar chassis, but a slightly shorter body, 58 ins. in length. The weight of this sidecar is 122 lb.

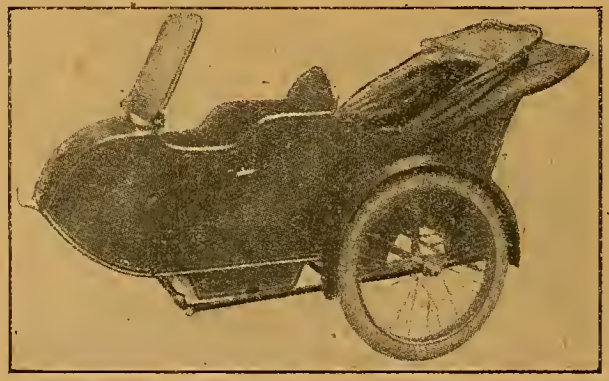
Model No. 3 is a much cheaper and lighter type than the others. The chassis is not underslung, and three-point attachment is provided. The mudguard is 4½ ins. wide, and has no valance, but the quality of the tubing and fittings is maintained. The body is 58 ins. long, but the weight complete is but 110 lb.

Extras, which can be fitted to all models, are: 28 in. wheel, Triplex glass screen, luggage grid.

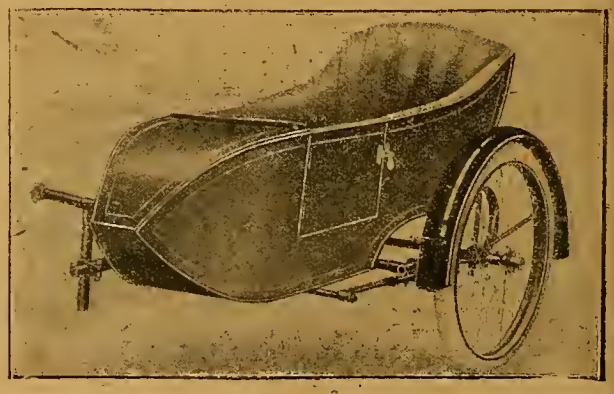
Stand No. 27.
Henderson Sidecar, Aero Works, Fitzwilliam Street, Sheffield.

THE Henderson sidecar has been designed on most attractive lines, and its graceful appearance and high-grade finish will make a strong appeal to the æsthetic. The body, while being roomy and very handsomely upholstered, is by no means clumsy or unwieldy. It is fitted with a bulbous back, which masks a compartment large enough to take quite a quantity of luggage.

Refinement in detail has been studied, and an instance of this is the extremely neat method of housing the lamp, which the law now compels all sidecar users to carry, under the small step shown in our illustration on the side of the body. The chassis is composed entirely of straight tubes, and the method of springing employed ensures a low centre of gravity. The new spring frame model, which is exhibited for the first time, is well worth special inspection.



For the family man—the tandem-seated Montgomery.



A simpler and lighter type of Montgomery sidecar.

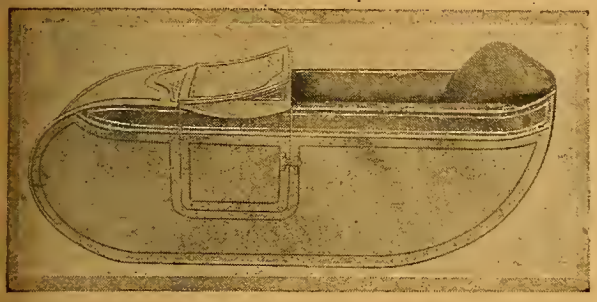
Sidecars for all Types of Machine—Two New Spring-wheel Suspensions.

Stand No. 98.

Mead and Deakin, Rushey Lane, Tyseley, Birmingham.

MESSRS. MEAD and DEAKIN are exhibiting a range of their sidecars for 1920. It will be remembered that this firm was the first to introduce coach-built sidecars on streamline ideas, and the models shown come up in every way to the high standard of design and efficiency for which the firm is noted.

The ordinary Minor, Sporting, and Standard models are shown, and in addition there is one called the Military, which, although it has been manufactured before, has not as yet been put upon the market. This has a somewhat larger body than the Standard, and is fitted with Cee springs instead of the usual Canoelet laminated springs. An entirely new model with body made of sectional stampings acetylene-welded together, with a new system of springing, is under construction to be ready soon.

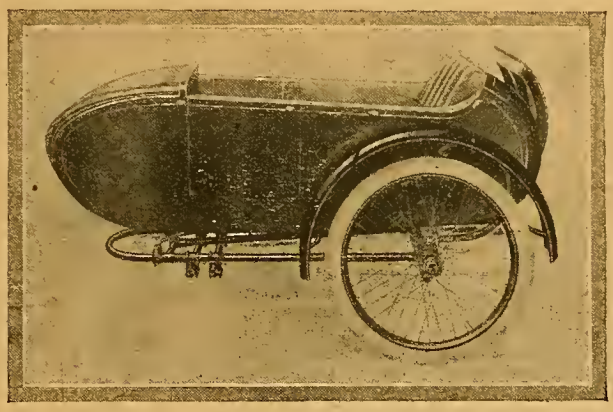


A well-finished sidecar by the Birch Aircraft Co.

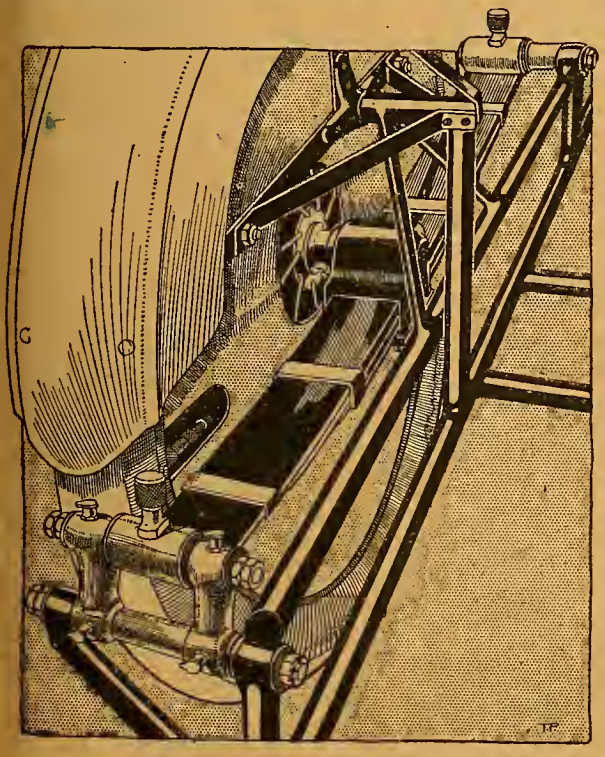
Stand No. 35.

The Birch Aircraft Manufacturing Co., Ltd., 169-171, High Road, Willesden Green, London, N.W.

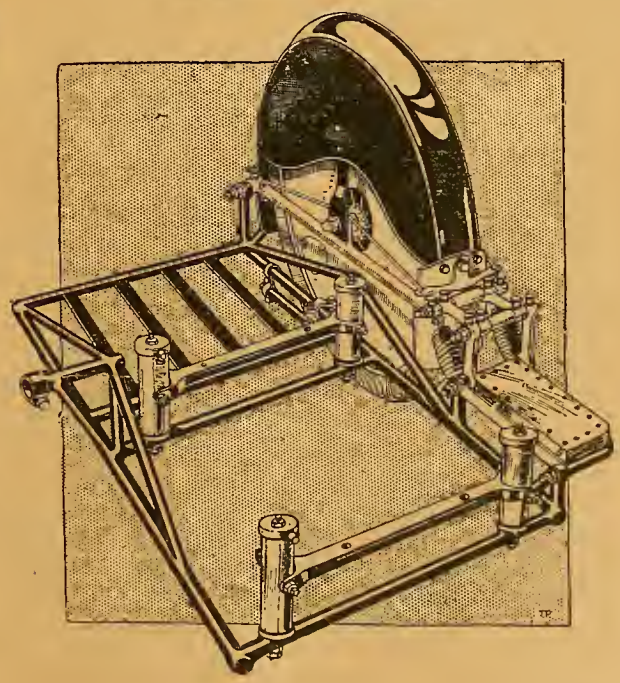
THE objects of principal interest on this stand are two very well-designed spring-wheel sidecar chassis. One of these incorporates a single leaf spring, to which the wheel is attached direct. The spring is carried in a tubular framework, and is provided with a substantial shackle of large dimensions at the near end. All the spring bearings are provided with large grease caps, and are of hardened steel. The other model is fitted with two coil springs. The wheel, which is easily detachable, is mounted in a rectangular framework, which is pivoted at the rear end. At the foremost extremity are two links, which are attached to a small rectangular member pivoted on to an extension of the chassis. Two coil springs are interposed between the framework carrying the wheel and the rectangular pivoted member. The springing action can be better understood by referring to the accompanying sketch. During the war this concern has had considerable experience in oxy-acetylene welding in aircraft work, and they have now applied this to the production of their sidecar chassis, which are quite free from lugs, all the tubes being welded together. The neat aluminium step fitted is a useful adjunct, and adds considerably to the appearance.



The well-known Canoelet sidecar, which has the mudguard attached to the body, and a very capacious locker in the back.



Two novel spring-wheel suspensions to be incorporated in Bamco sidecars.

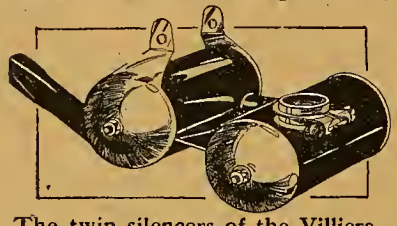


SECTION 4.—ENGINES: Villiers, M.A.G., Abingdon and Stanger.

Stand No. 234.

Villiers Engineering Co., Ltd., Blakenhall, Wolverhampton.

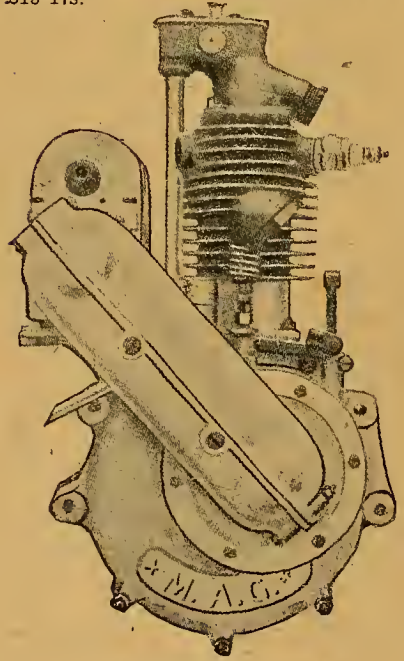
THIS company has many specimens of its successful 2½ h.p. engines on the stand, yet seldom is the quantity sufficient to go round among the many



The twin silencers of the Villiers.

inquisitive visitors who besiege it. In common with all two-strokes, simplicity is the keynote of its design, and on this example it is accompanied by substantial construction without superfluous masses of metal. Special attention has been paid to the contour of the piston baffle, this counting for so much in two-stroke engines, the makers only adopting the present piston after strenuous and exacting tests. Three piston rings are used, two at the top and one at the bottom; all are pinned to avoid the gaps coming in line. The big-end of the connecting rod has roller bearings, while the main bearings are of phosphor-bronze, of good length and positively gastight. Oil is led direct from the supply to the engine through a hollow crankcase bolt, the system being patented by the Villiers Co. The cylinder capacity is 269 c.c., the bore and stroke being equal to 70 mm. by 70 mm.

M.-L. or C.A.V. magnetos are fitted, the choice of carburetter being left to the several manufacturers building machines with this unit. The price is £19 17s.

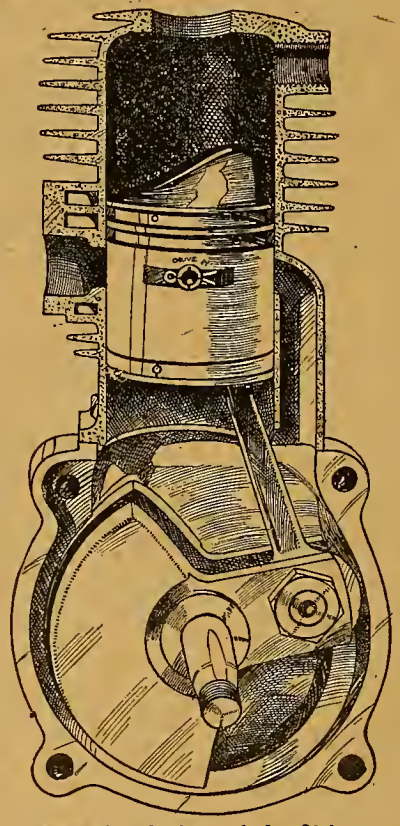


An interesting 2½ h.p. M.A.G.

Stand No. 202.

M.A.G. Engine Co., Ltd., Harrow Road, Willesden Junction, N.W. 10.

A FEATURE of the new M.A.G. engines is the starting handle, which is connected direct to the crankshaft. Being of large dimensions, it renders it possible, if one so desires, to swing the engine over compression when starting up. The push rods operating the overhead inlet valves on all models will in



A sectional view of the 2½ h.p. two-stroke Villiers.

future be fitted with enclosed adjustment at the top in the same way as it is carried out on the M.A.G. engines fitted to Morgan runabouts.

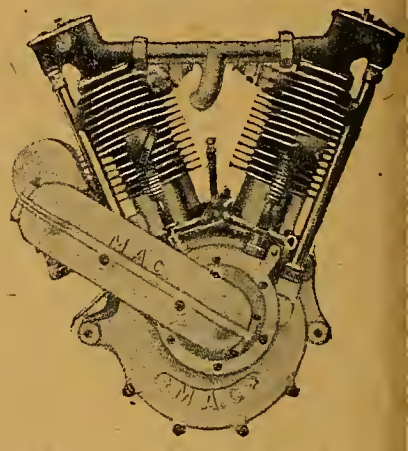
Two V-twin engines are shown, an 8 h.p. and 3½ h.p. An interesting little engine is the 2½ h.p. single. All three types will be imported into this country in large quantities during the coming season. M.A.G. engines were deservedly popular before the war, and have an even finer future before them. They are noted for their excellent finish and cool running.

Stand Nos. 34-140.

Abingdon-Ecco, Ltd., Tyseley, Birmingham.

THIS exhibit includes, in addition to the famous 6-7 h.p. Abingdon Ecco twin-cylinder engine, a variety of the components and accessories which will appeal to motorcyclists on account of their fine quality and their fitness for the purpose for which they are intended.

Prominent among them will be found the King Dick spanners and tool kits—the former "guaranteed for ever"—also the well-known King Dick belt fasteners, and representative assortments of



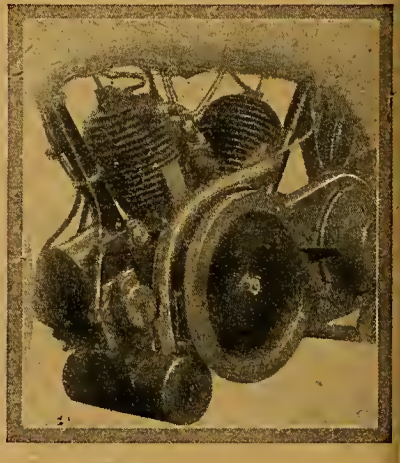
Two twin M.A.G.s are shown—a 3½ h.p. and an 8 h.p.

finished articles, such as lubricators up to 2 ins. diameter, petrol needle valves, petrol filler caps and sidecar hubs.

Stand No. 28a.

Trotman Patent Dandy and Co., Ltd., Dandy Works, Wood Green, London.

A NOVELTY on this stand is the Stanger V-twin two-stroke engine. The cylinders are set at an angle of 45 degrees and are staggered. The crankcase is divided longitudinally, thereby providing two compression chambers, one for each cylinder. The crankshaft is set at an angle of 180 degrees. The engine is rated at 5 h.p., and is suitable for fitting to most types of standard frames. A. Hazelwood and also a P.V. spring frame machine are shown at this stand, fitted with this power unit. It is hoped that deliveries will commence immediately after the Show.



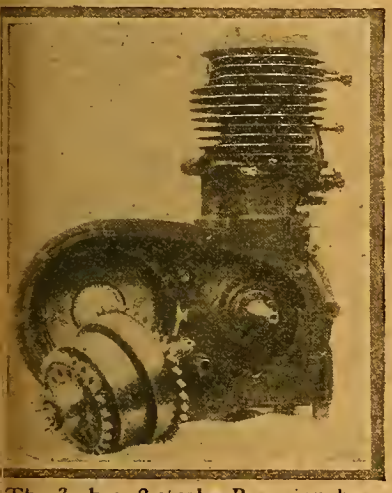
The twin two-stroke Stanger, which has a two-throw crankshaft and twin crankcases.

ENGINES. – Precision and Coventry-Victor.

Stand No. 207 (Gallery).
F. E. Baker, Ltd., Precision Works, King's Norton.

ON this stand are shown the latest products from the Precision works. The twin engines are entirely new, and three of them are shown, suitable for heavy outfits or cyclecars.

The 8 h.p. engine has a bore and stroke of 85 mm. by 85 mm., which gives a cubic capacity of 964 c.c. The other two have a longer stroke, 96 mm., the bore being the same, 85 mm., which gives a capacity of 1,096 c.c. Excepting in size, the three engines are similar in design, with large valves placed side by side. The timing gear has been completely re-designed. The fins on the air-cooled models are cast square in place of the more usual concentric fins.



The 3½ h.p. 2-stroke Precision has an ingenious lubrication system.

A feature which makes for easy starting and slow running is a stuffing box device on the inlet valve stems; this entirely eliminates air leaks at this vital point. Lubrication is by splash, and the crankcase is fitted with a simple but effective breather which acts as a non-return valve. The timing case is lubricated through this breather and superfluous oil is carried quite clear of the engine by an oil vent from the timing case

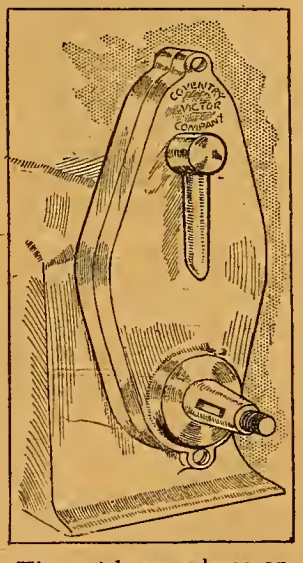
Stand No. 145.
Coventry Victor Motor Co., Ltd., 137, Cox Street, Coventry.

WE find here two models of the Coventry Victor 5-7 h.p. horizontally-opposed twin engines, one air-cooled and one water-cooled. The dimensions are identical in both cases, namely, 75 mm. by 78 mm. (688 c.c.). The crankcases present a remarkably clean appearance, and are supported in the frames of their machines by two parallel grooves which fit frame members to which they are clamped.

A Coventry-Victor connecting rod.

The crankshafts are the customary two-throw pattern of this type of engine, and the big-end design is ingenious, having its bushes in the form of a D, which facilitates their removal when eventually necessary. The valves are large, and situated at the top of the cylinder, working horizontally with adjustable tappets. Mixture is furnished by the new pattern Amac carburetter, while either a Thomson-Bennett or C.A.V. magneto supplies the spark. At £38 10s. this engine is an attractive proposition.

Another exhibit here is the Speedway two-speed gearbox, a very workmanlike job with constant mesh pinions and sliding dogs. When the cover is taken off the whole internal mechanism may be removed without taking the gearbox from its frame. The Warner patent rear spring fork should also have a few minutes' attention, embracing as it does several novel features of which space forbids description.

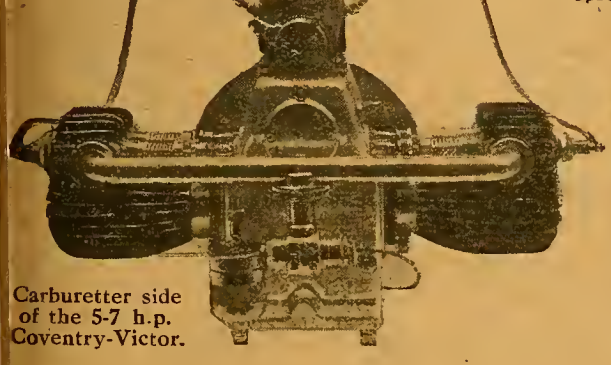


The crankcase release on the Coventry-Victor blows oil on to the front sprocket.

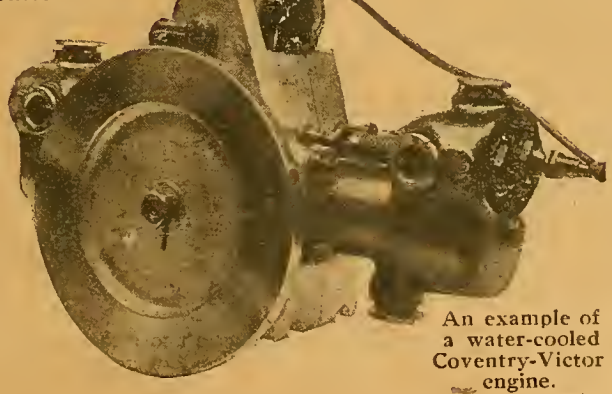
Another view of the 3½ h.p. 2-stroke Precision.

Stand No. 172.
Hobday Bros., Ltd., 23, 25, 27, Gt. Eastern Street, London, E.C. 2.

THOSE who favour the two-stroke engine would do well to inspect the latest Dalm engine shown on this stand. It is a 3 h.p. two-stroke of particularly sound construction. There is also a large display of most of the leading lines of accessories



Carburetter side of the 5-7 h.p. Coventry-Victor.



An example of a water-cooled Coventry-Victor engine.

SECTION 5.—IGNITION AND LIGHTING APPLIANCES.

Stand No. 166.

Vandervell, C. A., and Co., Ltd., Warple Way, Acton Vale, London, W. 3.

THE two chief items of interest on this stand are two new types of magneto—the K.U.1 and the K.U.2. The former is a lightweight magneto for single-cylinder four and two stroke motorcycles up to 3 h.p. It is sold complete with high-tension terminal at £6 12s. 6d. The K.U.2 is for twin-cylinder motorcycle engines up to 3 h.p., firing at 180 degrees. The price of this model is £7. These two new models have been designed to take the place of the original C.A.V. magnetos, models 3U1 and 2U2 in the case of machines of low horse-power, where small weight and size are important considerations. They are of the single-magnet type and totally enclosed. It is practically impossible for water to enter under any circumstances; in fact, it is possible to immerse them in water and still obtain satisfactory running. These magnetos embody the same type of armature as the larger models and the well-known C.A.V. contact breaker. Another point worthy of note is the carbon brush holder and terminal, which are made in one, and thus ensure a secure electrical connection, which is quite waterproof.

Section of a C.A.V. high-tension brush.

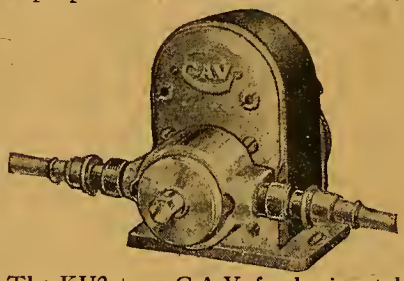
Stand No. 213.

M.L. Magneto Syndicate, Ltd., Victoria Works, Coventry.

THE M.L. Magneto Syndicate was one of the first to take up the threads of the German industry in 1914, and produce a thoroughly reliable article of all-British manufacture. During the war they supplied no fewer than 50,000 magnetos to the authorities, many of which were fitted to W.O. Triumphs. On one part of the stand is shown a magneto actually running and functioning properly under water.

Another position is devoted to the display of separate parts, and shows the various stages of manufacture from the raw material just as it arrives at the works to the finished article ready for fitting. Armatures and condensers are shown in the many stages through which they have to pass before completion, and sectional models help the uninitiated to understand the relation of one part to another. A further section demonstrates testing processes for regularity of sparking both at high and low speeds. Individual parts are also shown under test, notably the armature, which is subjected to a high frequency alternating current of 1,500 volts.

The complete magnetos displayed include a full selection suited to motorcycle engines, from the P.M.1 and P.M.2 for single and twin lightweights respectively, to the C4 for engines having four cylinders. The special features which should be examined are the laminated pole shoes, a new pattern condenser, jump spark distributor, and the non-hydroscopic pivot bush in the contact breaker.

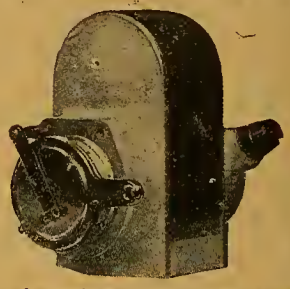


The KU2 type C.A.V. for horizontal twins.

Stand No. 151.

Sphinx Manufacturing Co., Bradford Street, Birmingham.

ONE of the most popular of sparking plugs is the Sphinx Speed model, which is on view with all the other types of this well-known make. All have been improved in detail, and it must be remembered that the experience gained during the war has taught us much in relation to internal-combustion engines and their equipment. A new model is on view, known as the Bor type. Two circular bars are placed at right angles, forming the electrodes. It is claimed that a weak current is concentrated between fine points, the nearest approach of the two bars to one another, as a little thought will show. When the current increases the makers claim that the gap increases also, thus easier starting and slower running should be given, with the maximum efficiency at high speed. The plug is made with either mica or ceramic insulation, and is said to be suitable for all varieties of engines.

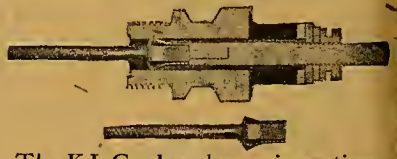


Another view of the M.L. single-cylinder magneto.

Stand No. 204.

E.I.C. Magnetos, Ltd., Sampson Road North, Sparkbrook, Birmingham.

THE E.I.C. Co. are exhibiting magnetos for single or twin-cylinder motorcycles. These are shown in various types: Type A, which weighs 6½ lb., has proved very satisfactory on two-stroke engines; type "A Ref. D," weighing 7¼ lb., is specially designed for large single-cylinder engines, and gives a hot flame spark at low speeds, whilst remaining efficient at any speed the engine is capable of developing. Twin-cylinder magnetos are represented by the type "A2" for 180 degree small twin-cylinder engines, such as the 2¾ h.p. Douglas, and the type "A2 Ref. D" for 180 degree large twin-cylinder engines.



The K L G. plug cleaner in section.

The design is in accordance with well-tried practice. The insulation is tested at each stage of building up, and the armature windings and condenser are perfectly balanced. E.I.C. magnetos are constructed in such a manner as to require no oil, and the danger of over-lubrication is thus avoided.

Stand No. 83.

Chater Lea, Ltd., 74-84, Banner Street, London, E.C.

A NEAT high-tension cable terminal which, although not particularly well known, has yet been on the market for some time, is a little speciality of this concern. To fix the cable, it is only necessary to bare about an inch of the wire, and push it well home into the terminal, and give the slotted portion a sharp tap with a hammer. This holds the wire securely in position.

A group of M.L. magnetos, showing (left to right) the single-cylinder, lightweight and twin-cylinder types.

The Lucas Magdyno, Thomson-Bennett Magneto and Some Plugs.

Stand No. 191.

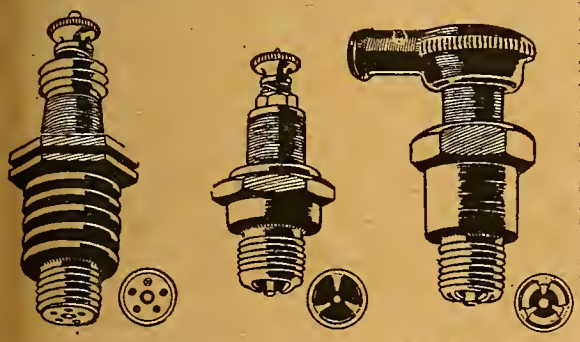
Lodge Sparking Plug Co., Ltd., Rugby.

SINCE the very earliest days of motoring Lodges have been inseparably associated with plugs, and their several types to suit all engines are known to all patrons of the petrol vehicle.

The standard model is the C3, suitable for nearly all English motorcycles. Its construction permits of its being taken apart for cleaning purposes. Model C9 is a similar plug, but is non-detachable. Both these types are sold at 5s. The Model MB is also suitable for most English machines, and adds to its merits security against bad weather conditions, its high-tension parts being all enclosed and so protected from rain, and at 7s. 6d. is excellent value for money.

The smallest pattern, CE2, specially made for machines of small tank clearance or small engines, such as scooters and auto-wheels, where a large plug looks out of place, is retailed at 6s. The KR3 is an aero type suited to racing by virtue of its constructional facilities for cooling, which permit of its use in very high compressioned engines without fear of pre-ignition or other troubles. This model is priced at 8s. 6d.

A new plug, embodying a priming device, is also shown, priced at 13s. 6d.

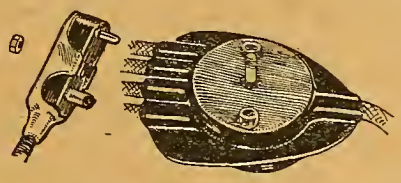


Lodge motorcycle plugs, showing the Aero. Baby (for lightweights) and waterproof types.

Stand No. 189.

Lucas Electrical Co., Ltd., Birmingham.

THE famous Thomson-Bennett magnetos which have assisted in so many aerial exploits and are equally well known in the motor-cycling world are seen here, as the Lucas Electrical Co., Ltd., are the successors to Thomson-Bennett Magnetos, Ltd., and are now undertaking the electrical side formerly handled by the parent company, Joseph Lucas, Ltd. In addition to the magnetos, much interest centres round the new Lucas Magdyno. This is a combination of the Lucas 6-volt lighting dynamo and the Thomson-Bennett magneto, and although both instruments are combined in a single unit, they are electrically separate. The small cylindrical dynamo is on standard Lucas lines and is housed in the magnet of the magneto and driven through a train of gear-wheels from the magneto shaft. The necessity of a separate drive for the dynamo is thus eliminated and a saving in weight is also effected.



The Magdyno junction box.

This, one of the most interesting novelties at the Show, was described fully in a recent issue. The junction box and switch are of particularly neat design, and the instrument as a whole appears to be singularly well thought out.

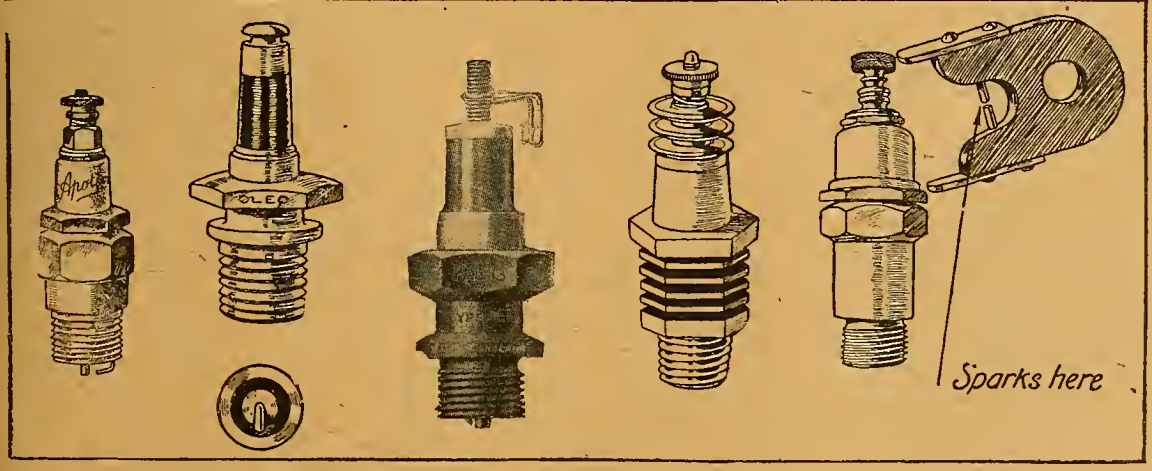
Stand No. 214.

Ripault, Leo, and Co., 1, King's Road, St. Pancras, London, N.W.

THE chief items of interest here are the Ripault lever compression tap and the Oleo plugs. The compression tap is operated by means of a screw-down tap and is perfectly gastight when closed. The aviation type Oleo plugs are of particular interest, as they were selected by the Air Ministry in favour of all other plugs for super-compression engines. The insulation of the mica is tapered, forming a perfect joint, while the electrode is of nickel steel of high tensile strength which is guaranteed against pre-ignition and oil.

The switch of the Magdyno is operated by one knob.

The Oleo waterproof terminal is suitable to attach to any plug fitted with a spigot end and can be easily connected or disconnected. It is unaffected by vibration and consequently always remains in perfect contact. This is sold for 1s. A novel plug tester is also on show. The construction of this will be easily seen from the accompanying illustration. It forms an easy method of testing the plug whilst in the engine. If the plug is short circuiting no spark will appear between the electrodes of the tester. This is priced at 2s. 6d.

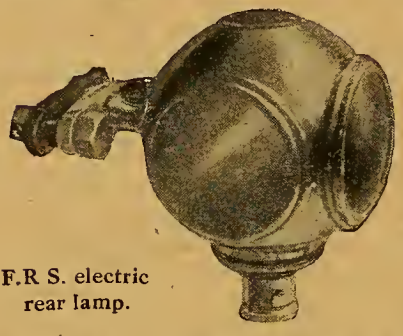


From left to right: The Apollo aviation plug, the single-point Oleo, the K.L.G., the racing Forward, and the Leo Ripault spark tester.

WELL-KNOWN LIGHTING SETS: F.R.S., Hunt, Smith, and Lucas.

The F.R.S. Lamps, Pershore Street, Birmingham.

MANY riders have facilities for charging accumulators easily, and the F.R.S. combination electric lighting set appeals very strongly to such. It consists of headlamp, side lamp, tail lamp, aud accumulators, and a pressure of 4 volts only is utilized. The headlamp is strongly constructed, and is 7 ins.

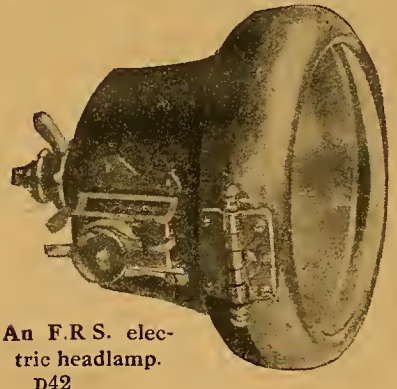


F.R S. electric rear lamp.

in diameter. It has adjustable side sockets attached to handlebar fittings. The secret of the success of the lamp is the parabolic reflector in conjunction with the special filament bulbs. The focus is adjustable, and the bulb may be removed while still alight from the rear of the lamp, thus providing a ready and useful inspection lamp.

The side lamp has a small screw bulb which is also removable while alight, and the tail lamp follows the same practice. The accumulator is carried in a stout teak box, and provides current for 20 hours light. The standard set is priced at £8 8s., but with 6-volt battery it costs £9 10s. A set for solo machines has a 5½ in. diameter headlamp, with the accumulator carried in a black polished box which fits on the top tube of the machine. This is priced at £6 10s. Other useful exhibits are the adapters to allow electric lighting to be used in existing gas lamps. This is a small clip, carrying a 3½-volt bulb and small reflector, which fits over the existing burner. The mirror lens of the lamp is used and the focus is not disturbed. The price of this small fitting is 4s. 9d.

The well-known F.R.S. system for utilizing the primary current of the magneto for lighting purposes is again on sale. A small side and tail lamp set for sidecars is also interesting. The side lamp is egg-shaped and the tail lamp is spherical, both are fixed in position by a single bolt and nut which projects from the lamp body.



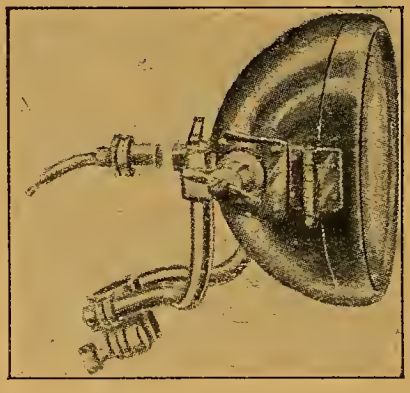
An F.R S. electric headlamp.

D42

Stand No. 178.

Hunt, A. H., 115-117, Cannon Street, London, E.C. 4.

A LARGE selection of accessories are on view at this stand, including electric lighting sets for cyclecars, motorcycles and sidecar combinations, which are complete in every way, and include lamps, batteries or accumulators and carrying cases for solo machines. A particularly good electric headlamp is the Daylight, made either for attachment to the handlebar stem or the cross member. There is a large variety of electric rear lamps with and without combined switches. Most types of the Hellesen dry battery are on show, and accumulators of special design to stand road vibration such as is met with on motorcycles. Other items are metal and leather battery carrying cases, ignition coils, high and low tension cables, Morse signalling lamps, and voltmeters and amperemeters, which are particularly well finished with jewelled movements. Amongst the novelties are special A.A. badge clips for attaching the A.A. badge to the number plate, handlebar match boxes and route card holders.



The Daylight lamp, by Hunts.

Stand No. 209.

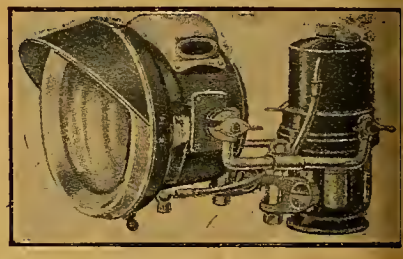
Smith, S., and Son (M.A.), Ltd., 179,185, Great Portland Street, London, W. 1.

THE Smith equipment comprises a very complete and up-to-date range of motorcycle accessories. Every article offered by this concern is built for the highest standard of quality and efficiency, and is guaranteed thoroughly reliable in operation. Their exhibits include speedometers, revolution indicators, carburetters, lighting systems, electrical, mechanical and bulb horns, mascots, tyre pumps, and also M.L. magnetos, K.L.G. sparking plugs and Euk easy starters, for which this concern are the only selling agents. The now famous K.L.G. plug, the standard model of which will be adopted on post-war Rolls-Royces, is priced at 5s., and many other models for various type of engines are shown at 5s. 6d. and 10s. 6d.

Stand No. 189.

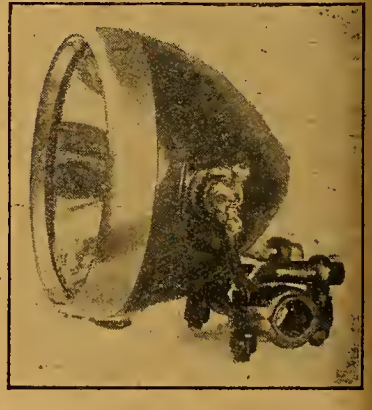
Lucas, Joseph, Ltd., Gt. King Street, Birmingham.

LUCAS equipment in every variety is handsomely staged, from the tiny but ever-useful "Girder Minor" spanner to the latest Lucas 6-volt. lighting set. The advantages of electric lighting are many, but perhaps the chief one is the absolute immunity from trouble. For such as prefer acetylene, or cannot afford



Lucas King of the Road set.

the luxury of an electrical outfit, there is the famous King of the Road headlight set with its many refinements, Mangin lens mirror, adjustable double bracket, instantaneously-removed carbide container, etc. The smaller pattern for lightweight machines, the King's Own, is also shown, and a variety of sidecar lamps, tail lamps, etc. The clean lines of the cyclorns, with the coiled tube contained in the body of the horn, are always admired, and a forced-feed oiler is an accessory which every rider should have in his private garage, as it



A Lucas electric headlamp.

ensures a positive supply of oil to the bearings, and is also very useful for lubricating Bowden cables, as shown in a recent article in these pages.

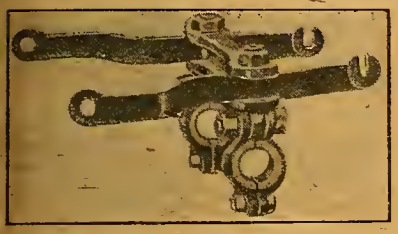
Lucas' Motoralities have long been held in high esteem by all riders, and there is no need for us to enlarge on their merits, except to say that the construction and finish are quite up to expectations.

Miller and Powell and Hanmer Lighting Sets—Cooke Plugs—B.L.I.C.

Stand No. 193.

Miller, H., and Co., Ltd., Miller Street, Birmingham.

A VERY representative display of electric and acetylene lighting sets is on view. Two patterns of acetylene lamps



The fixing of the Miller lamp set.

have been concentrated on, and these are known as 31H and 22H. The former set is fitted with a mangin lens mirror of 4 ins. diameter, and is supplied with a patented bracket for bearing both the projector and the generator. The strength of this carrier is such that al case of breakage is unknown. This desirable result is attained by careful selection of the material employed and the patented details of the design.

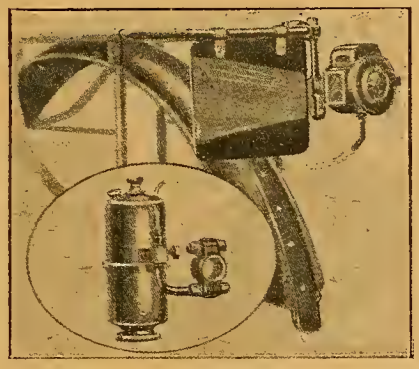
Both lamps and generators are made from the finest materials. The 22H model is similar in design and construction, but is smaller. The reflector is 3½ ins. diameter. The very neat tail lamp exhibited is particularly strong, and the neat carrying bracket, which is adjustable, is worthy of attention.

Stand No. 187.

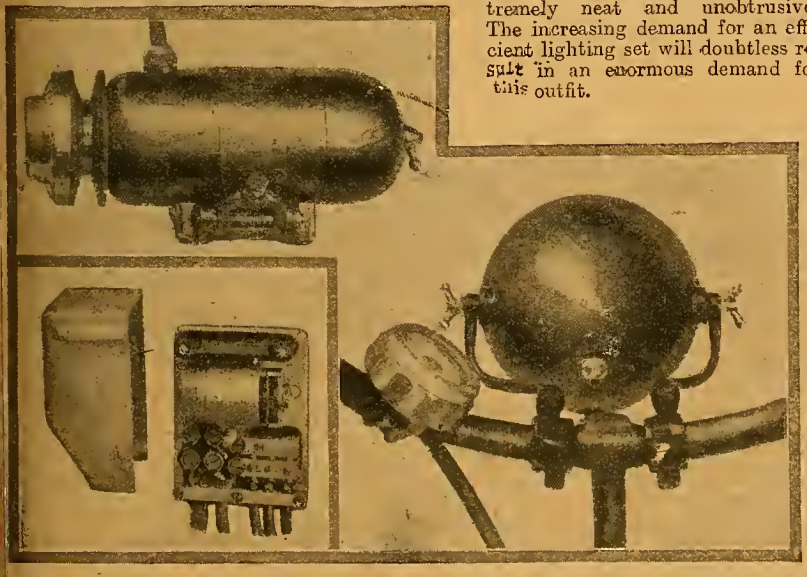
Powell and Hanmer, Ltd., Chester Street, Birmingham.

A FULL range of the well-known P. and H. lamps and generators is to be seen on this stand, and their sturdy construction is worthy of note. The chief interest lies in the dynamo lighting set, however. The dynamo is designed to give its full output of 6 volts 6 amps. at 1,440 r.p.m., and no matter what the speed of the motorcycle be the speed of the dynamo is kept constant by the use of the P. and H. patented control which works as follows:—

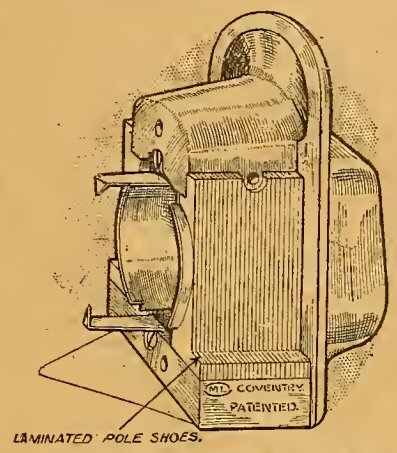
The control is in reality a patented clutch, consisting of a driving face and a driven face held together by the action of a spring acting through a toggle. Now for a certain output the power required can be calculated and the spring set accordingly. Should the speed of the machine rise the spring is unable to cope with the increased torque of the armature and the clutch accordingly slips. It is claimed that by this means a more efficient generator is possible than when electrical control by means of a third brush is relied upon. A very neat switch with an ammeter combined is also shown; it is designed to clip on to the top tube or the handlebar, and in addition to being waterproof is extremely neat and unobtrusive. The increasing demand for an efficient lighting set will doubtless result in an enormous demand for this outfit.



Showing the method of attaching the Miller rear lamp to the carrier.



The P. and H. dynamo set. A slipping clutch device is embodied in the driving pulley. Note the neat handlebar switch.



The maximum magnetic field is obtained on M.L. magnetos by the use of laminated poleshoes.

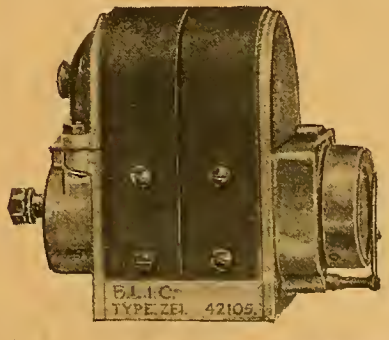
Stand No. 212.

Cooke, Howard S., and Co., 116-118, Northwood Street, Birmingham.

A FULL range of Cooke sparking plugs are on view, and as these plugs have lately made a name for themselves by functioning perfectly on an engine which has proved itself a devourer of plugs they deserve the attention they receive. Type B is particularly suitable for motorcycle engines, and is strongly constructed, its length overall is 3 ins. Having regard to the severe conditions of winter riding, the most interesting exhibit is the new Cooke weatherproof plug, which should entirely eliminate all trouble from this source.

Our own experience of these plugs used on a Harley-Davidson combination was very satisfactory, although a large number of other makes that had been tried had failed.

In addition a very neat terminal for the h.-t. wire is shown. This consists of a vulcanite bush, into one end of which the h.-t. wire slips. Into the other end a brass slotted hook screws. A portion of the h.-t. wire is bored and passes through a small hole in a partition in the vulcanite bush, being gripped between the partition and the shank of the hook. This fitting is easily assembled on the h.-t. wire, and no tools are necessary beyond a knife to bore the end of the h.-t. cable.

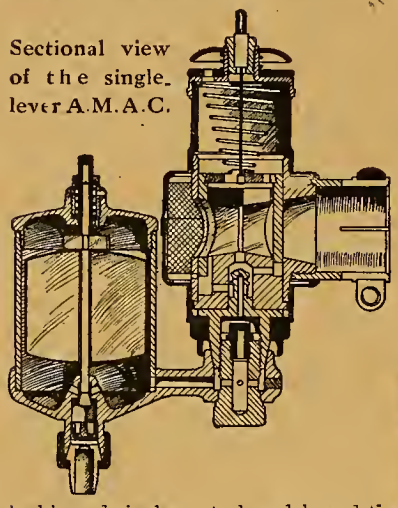


The B.L.I.C. single-cylinder magneto.

SECTION 6.—CARBURETTERS: A.M.A.C., Senspray and Everest.

Stand No. 152.
A.M.A.C., Ltd., Aston Cross, Birmingham.

THE most interesting exhibits on this stand are undoubtedly the new model carburetter. Special interest attaches to single-lever instruments at the present time, for which there is undoubtedly a growing demand. Four distinct types are shown: the vertical



Sectional view of the single-lever A.M.A.C.

double and single control models and the horizontal double and single control models. The same principle underlies all the types, that is, a submerged jet which merely serves to regulate the flow of petrol, and a vaporizing device. Air passing six minute holes forms a vapour with the petrol, and the manufacturers claim that liquid petrol never finds its way into the main inlet passage. The models are very similar in construction, but an adjustable air valve is found on the single-lever instruments, while the float chambers of the vertical and horizontal types differ slightly. Sectioned instruments show the action of the controls.

Stand No. 154.
Pugh, Chas. H., Ltd., Whitworth Works, Tilton Road, Birmingham.

LARGELY as a result of experience gained in the rapid strides made in aviation during the war, the internal-combustion engine of 1920 is a vastly improved unit, and possesses a degree of efficiency to which the improvements effected in carburation are in no small measure attributable.

Messrs. Charles H. Pugh, Ltd., who are well-known as the manufacturers of the carburetters fitted to the winning machines in both the Senior and Junior T.T. races of 1914, have effected several material improvements in the Senspray carburetter, and various examples of their 1920 models are shown at Olympia.

The most noticeable alteration at first glance is in the material now employed in their manufacture. The main body and the throttle chamber caps are now aluminium die castings, the latter being fitted with gunmetal bearings in which the throttle barrel spindle is housed. These end caps are detachable, and are held in position by a flat spring pivoted on the side of the body. The throttle barrel itself is now a gunmetal casting accurately machined.

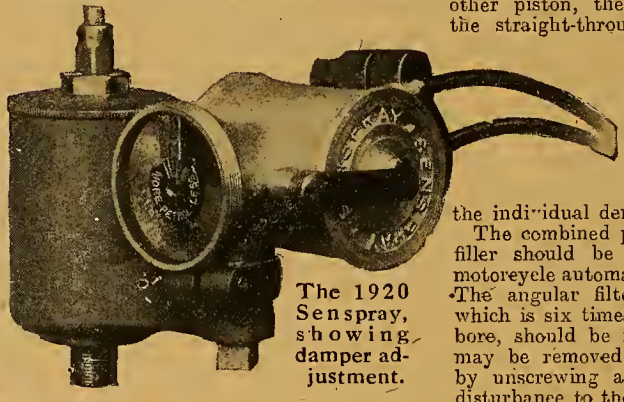
Appearance is not everything, however, and closer examination reveals the fact that the internal construction has

The new jet arrangement and slides of the two-lever A.M.A.C.

been improved by the introduction of a damper principle so arranged that it is proportionately and automatically cut out of action as the throttle is opened, and provides perfect slow running and economy.

The damper ports are adjustable by simple means as easily effected by the novice as by the expert.

The main characteristics of the old Senspray, viz., the straight-through



The 1920 Senspray, showing damper adjustment.

way, and the method of obtaining atomization are retained in the new models.

Of topical interest is the set of R.R.C.H. (Eagle) carburetters, as manufactured by Messrs. Pugh, and fitted to the Rolls engine on the aeroplane which accomplished the first successful transatlantic flight.

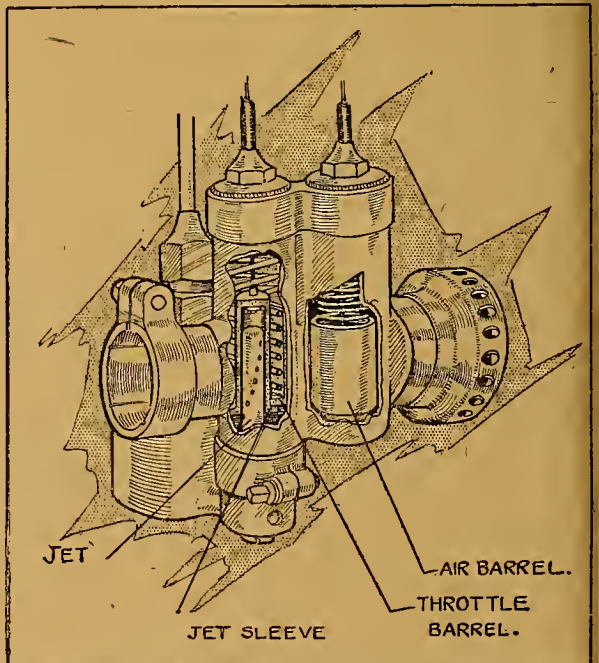
A variety of the well-known Alfred Appleby and Atco roller chains for motor and ordinary cycles, and a selection of stamped steel pressings, frame lugs, etc., complete this exhibit.

The Senspray carburetter had an enviable pre-war reputation as regards efficiency and economy, which the latest models should enhance considerably, both the finish and workmanship being excellent

Stand No. 184.
Messrs. Rotherham and Sons, Coventry.

THE Everest carburetter here shown has many points of refinement embodied in its design, and now has an additional barrel forming a separate control to the air supply. This is closed only for starting up, after which it may be left fully open, the other barrel controlling air and throttle opening simultaneously. The jet orifices are situated in the face of the jet tube in spiral formation, and a sleeve working in conjunction with the throttle uncovers one or more according to engine requirements. The throttle piston also controls the air supply subject to the position of the other piston, the carburetter being of the straight-through pattern. This instrument, recently, on a 3½ h.p. machine over give-and-take roads registered a consumption of 120 m.p.g., and by virtue of its construction is easily adaptable to the individual demands of any engine.

The combined petrol gauge, filter and filler should be seen, nor should the motorcycle automatic oil pump be missed. The angular filter, the gauze area of which is six times greater than the pipe bore, should be inspected. This gauze may be removed for cleaning purposes by unscrewing a hexagon cap without disturbance to the unions.



The Everest carburetter, made by Rotherham's of Coventry.

The Binks Carburetter—The B. and B. Variable Jet Model.

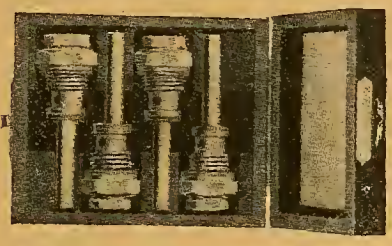
Stand No. 209.
Brown and Barlow, Ltd., 8, Laurence Pountney Hill, Cannon Street, London, E.C.

THE various models of the famous B. and B. carburetters are on view, and include the B.S.V. modet, the single jet model, the universal model with variable jet, the two-stroke carburetter, and a two-stroke model with variable jet. The B.S.V. model has a needle attached to the throttle slide. This needle works in the jet orifice and, being tapered, the jet is varied in size according to the throttle opening. The jet is situated in a small choke tube, and over the jet is a cap in which several small holes are drilled. The petrol spray and air have to pass through these small holes, and are still further broken up and mixed together, thus ensuring perfect vaporization.

The single jet model is practically automatic in action, and, having started the engine, the air lever is thrown open to a position depending upon the size of the jet. The carburetter is then automatic in action, and is controlled only on the throttle lever until a severe overload of the engine, such as on a hill, calls for a reduction in the air supply. The two-stroke carburetters are on this principle.

Stand No. 220.
Binks, C., Ltd., Phœnix Works, Eccles, Manchester.

ON this stand is exhibited a varied assortment of motorcycle accessories, of which, perhaps, the best known is the Binks carburetter. Practically no



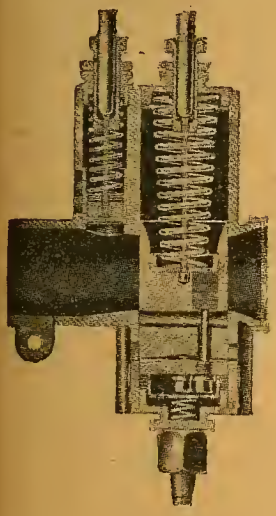
B. and B. jets can be obtained in a neat case to fit the waistcoat pocket.

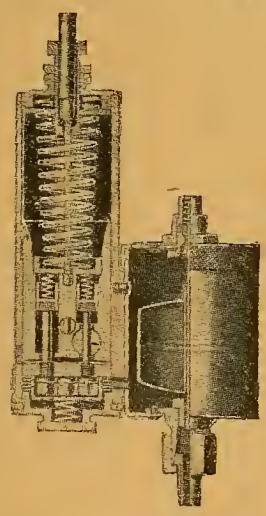
alterations have been made for next year, the three-jet principle, with damping device, still being employed. The action is as follows: when the throttle is practically closed, and the engine just ticking over in neutral, only a very small pilot jet is in use, but as the throttle is opened up so two larger jets are successively uncovered and supply more petrol to carburet the greater volume of air admitted. Two levers are provided, so that the extra air supply can be regulated. Great petrol economy and efficiency are claimed for this carburetter.

For Scott machines a special two-jet model is recommended.

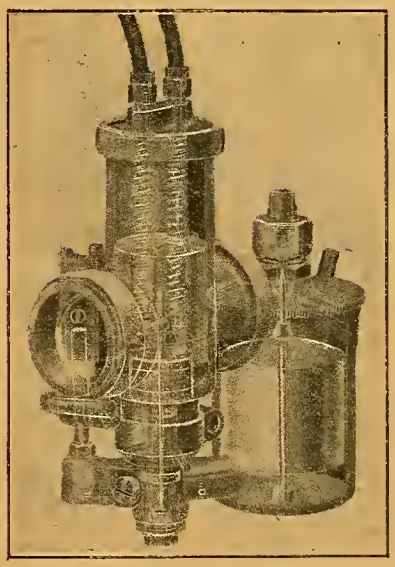
A new departure for this concern is the manufacture of a sparking plug, the special feature of which is a quick-detachable high-tension terminal that can be operated when the engine is running, in order to test if the cylinder is firing properly. The wire is held by a spring-loaded insulated knob, which has only to be lifted to release the wire. It is impossible for the wire to detach itself.

Silencers, filters and hot-air muffs are also to be found amongst the exhibits on this stand.





A sectional view of the Binks carburetter.



The B. and B. variable jet model.

Stand No. 146.
Stonehouse Works Co., Spon Lane Mills, Houghton Street, West Bromwich.

VARIOUS specialities and accessories are displayed on this stand, and they are especially interesting as they are produced by the manufacturers, who have their own rolling mill, from the raw material. Very extensive works and plant development is nearing completion, and the output will shortly be trebled. Motorcycle belt rim brakes were a speciality of this firm before the war, and although they had to be dropped to give place to urgent war material their manufacture is again well under way.

A strongly-constructed tyre pump is also shown, and although apparently of celluloid it is in reality a metal pump with celluloid covering. Another exhibit of interest to the rider who prefers to do his own small repairs is a very strong hacksaw frame.

Stand No. 7.
Roberts, Alfred, and Sons, Ltd., Gripwell Works, Gt. Lister Street, Birmingham.

A FULL range of this company's manufactures is shown on Stand 7. In addition to their well-known goods some new and interesting lines are exhibited. These include gaiters, plasters, horn bulbs belts, repair outfits, motorcycle covers and tubes, radiator hose, gas tubing, valve parts, prepared patches, security bolts, vulcanizing materials, brake blocks, rubbers for footrests, lamp and pump washers, rubber solution in tubes and tins, reinforced liners, and all moulded and tubed goods.

Stand No. 201.
Bowden Brake Co., Ltd., King's Road, Tyseley, Birmingham.

ON this stand are shown all types of Bowden wires and casing, including the well-known Bowdenite and Bowdenoir, which are almost universally used for controls of motorcycles from the smallest two-stroke valve lifter to the heaviest flexibly-controlled back brake. In addition are exhibited complete sets of Bowden handlebars, fitted with controls, including various models of valve lifter, magneto, carburetter, and clutch controls. The various appliances are in such profusion that they defy adequate description

SECTION 7.—TYRES, etc.: Dunlop, Kempshall, Avon and Bates

Stand No. 67.

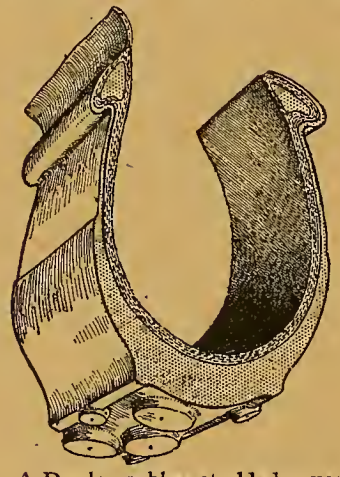
Dunlop Rubber Co., Ltd., Aston Cross, Birmingham.

THE Dunlop Rubber Co. are showing a complete range of their motorcycle tyres. These include the famous rubber-studded type, which are made in two-ply for solo work, three-ply for heavy solo work, and four-ply for passenger work. Rubber and steel covers are also exhibited, as well as the three-ribbed pattern. Various sizes in flat and rounded-topped motorcycle belts, as well as their usual range of accessories, are on view.

Stand No. 10.

Kempshall Tyre Co. (of Europe), Ltd., 97-98, Long Acre, London, W.C. 2.

A COMPLETE range of Kempshall tyres is exhibited. The round-tread anti-skid cover is now made with a solid tread, and is of heavier weight



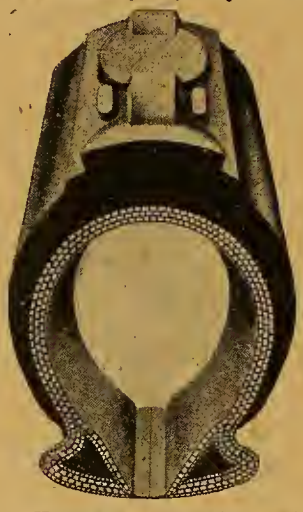
A Dunlop rubber studded cover in section.

in all sizes. The square-tread non-skid cover has also been improved, and in addition to gripping by suction, it now has transverse grooves in the tread, making it a still more effective non-skid cover. During the coming season all these tyres will be made under a special patent process, whereby the rubber is considerably toughened, and the life of the cover increased by at least 25 per cent.

Stand No. 44.

Avon India Rubber Co., Ltd., 19, Newman Street, Oxford Street, London, W. 1.

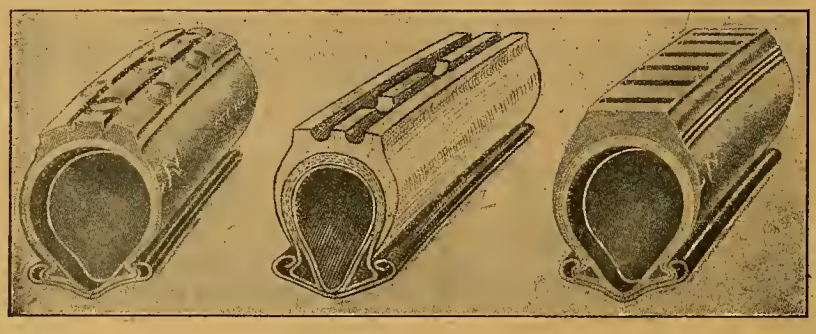
NO particular novelties are on view at the Avon stand, but the company are exhibiting very fully their well-



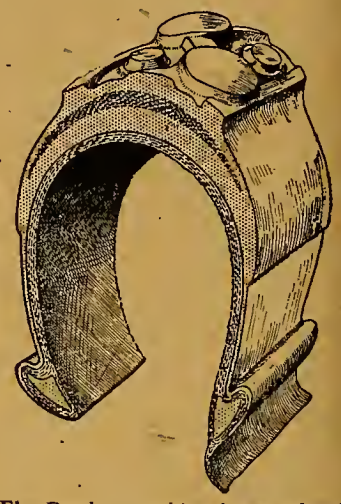
The Kempshall anti-skid tread.

known range of motorcycle tyres and accessories. Among the features of interest is the new Avon three-ribbed cover for high-powered machines with voiturette (motor flat base) rims, and the Avon Combination, a non-skid tyre combining rubber bars and steel studs, suitable for machines up to 5-6 h.p. Two types of Auto-Wheel covers are also worthy of notice, the six-line and the studded pattern, specially made for use on cycles fitted with motor attachments. These tyres can in a number of cases be used for scooters.

Also on view is the rubber compound and canvas belt, with Watershed top to conduct water safely beyond the engine pulley. Another interesting exhibit is the Avon Dome-end tube, a novel device ensuring perfect locking, absolutely air-tight, and quickly detachable. The Avon Co.'s useful motorcycle gaiters and shaped motorcycle plasters, specially intended for tyre cuts or bursts, are worthy of notice among the items on view.



Three types of non-skids. From left to right—Avon Stonehenge, Bates and Avon Sunstone.



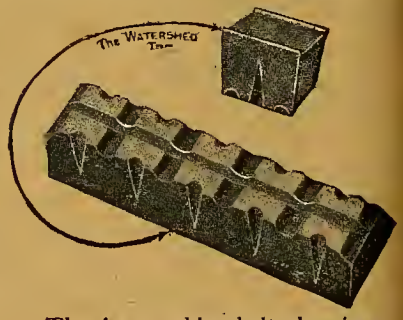
The Dunlop combination steel and rubber tread.

Stand No. 131.

Bates, W. and A., Ltd., St. Mary's Mills, Leicester.

TYRES, belts, repair bands, gaiters, etc.

Among a representative exhibit of this company's many products probably the well-known Bates tyres and belts will have the largest share of attention from motorcyclist visitors. The Bates No. 1



The Avon rubber belt, showing the Watershed top.

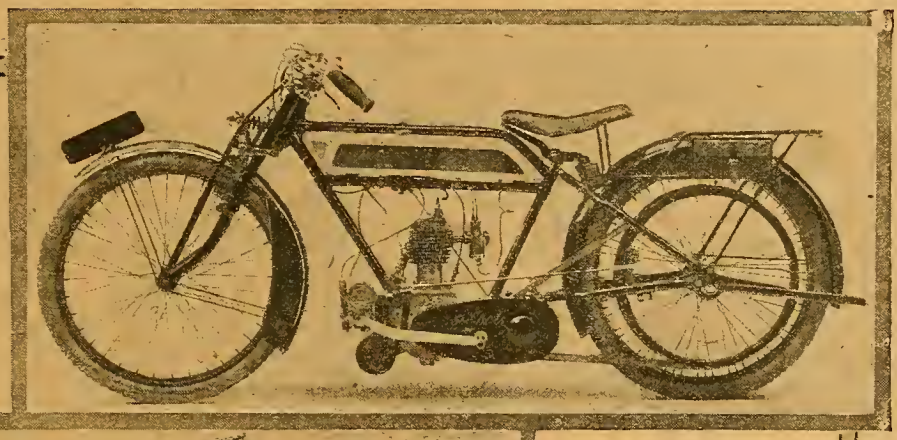
pattern, which has been with us since 1911, is of special interest on account of its recent success in the Johannesburg-Durban race revived this year. Messrs. Bates claim that, taking mileage into consideration, this production is the cheapest tyre obtainable, though its first cost is rather more than some of its competitors.

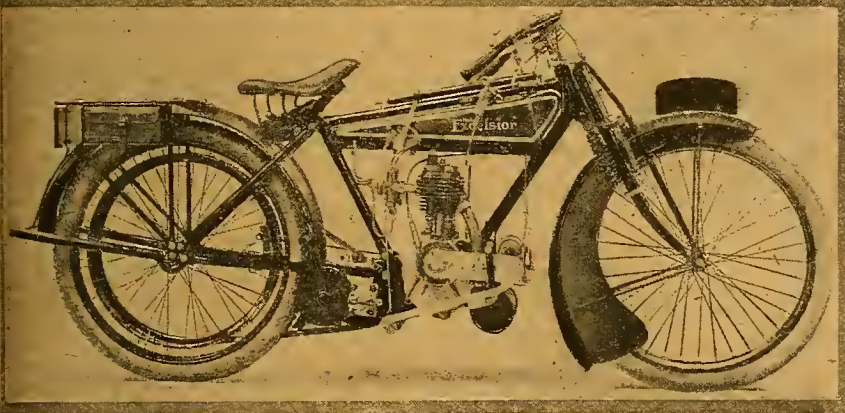
The No. 2 pattern is of the same quality, but has a three-rib tread, the centre rib being fluted at intervals of about 5 ins. A 26 in. by 2¼ in. cover costs 58s. and a tube 10s. The motorcyclette tyre at 23s. for the 24 in. by 2 in. size, and the sidecar tyre at 27s. 3d. for 26 in. by 2¼ in. are cheap tyres for low-powered machines.

The belts are full section, and the rubber is evenly distributed round the core. In their manufacturing process W. and A. Bates claim to have reduced stretch to a minimum without loss of flexibility.

SOME FOUR-STROKE LIGHTWEIGHTS.

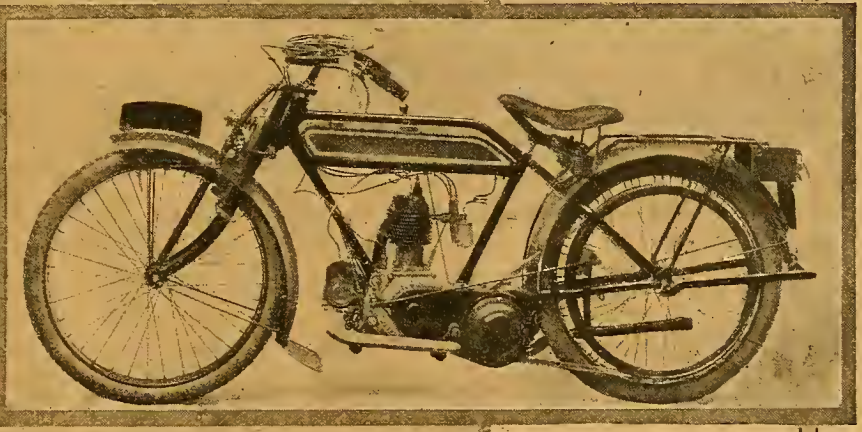
On the 2¾ h.p. Dot J.A.P. Saxon forks and the Albion two-speed gear are standard.

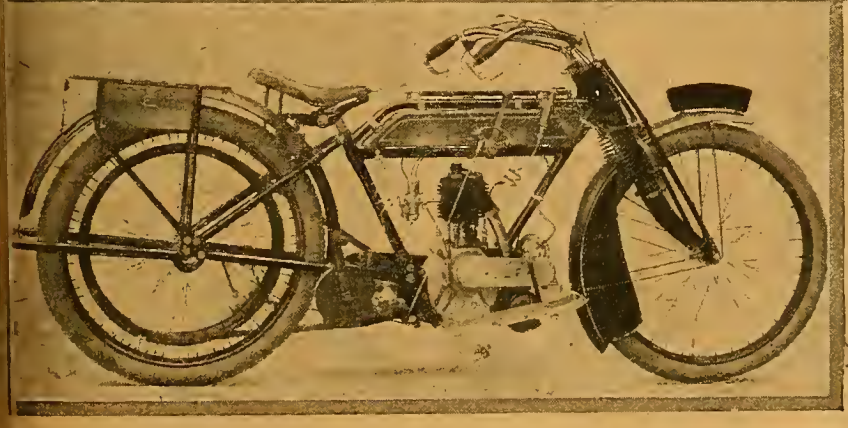




The Excelsior lightweight incorporates a Burman two-speed gearbox and a 2½ h.p. J.A.P. engine. A two-stroke lightweight is also made.

The popular New Imperial lightweight is fitted with a J.A.P engine, Saxon forks, and two-speed gear.





A Burman two-speed gear is fitted to the Wolf machine, which has efficient front mudguarding.

Various Types of Tyres for the All-weather Rider.

Stand No. 137.
David Moseley and Sons, Ltd., 19-20, Holborn Viaduct, London, E.C. 1.

PROMINENT among the exhibits of Messrs. David Moseley and Sons is the Moseley grooved tyre. This has been considerably improved of late, and has now a much greater air capacity. As is fairly well known, the Moseley grooved tyre, when new, comes into contact with the road on two of its five ribs. As these are worn down the other two are called into commission, consequently this type greatly reduces the tendency to skid on greasy roads. Other exhibits are steel-studded tyres, tubes, tyre gaiters, garage hose, matting and other rubber manufactures of interest to the motorcyclist.

Stand No. 134.
The Thames Rubber and Leather Co., 199, Upper Thames Street, London, E.C. 4.

A COMPREHENSIVE selection of rubber and leather goods, including such items of special interest as tyres, Rich Patent Tubes, motorcycle clothing and accessories, is on view at the Thames stand.

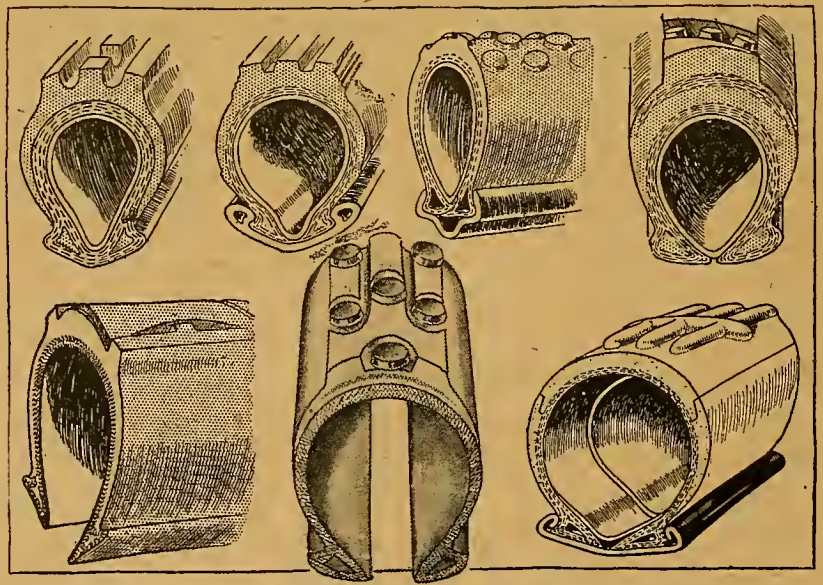
A variety of covers are exhibited, among which may be noted the Thames heavy, extra strong motorcycle tyre, for strenuous driving wheel work, rubber studded, and the Passenger, specially designed for high-powered machines and sidecar work. This cover is of the three-ribbed type, with four-ply casing. The Thames sidecar tyre, a seven-ribbed pattern, is of particular interest. It is made from the finest material, and is of ample thickness. Of special interest at the present time is the Thames Double Texture motorcycle suit, with double-breasted coat, warmly lined throughout, storm collar and cuffs, and ankle-leggings to match. Thames mud splashers, in imitation or real leather, are also among the exhibits.

Stand No. 68.
Etablissements Hutchinson, 70, Basinghall Street, London, E.C. 2.

FOUR interesting grades of motorcycle tyres, ranging from a light solo to the really heavy pattern, are noticeable among the Hutchinson exhibits. Commencing with the light covers, the Brooklands is shown for very easy work; next comes the Tourist Trophy, a medium cover for solo machines. For heavy sidecar work, in either the three-ribbed or rubber-studded pattern, the Passenger is on exhibit, while a still heavier type, made specially for use on motorcycles fitted with voiturette rims, is the Hutchinson three-rib, a really hefty cover, which is specially adapted to punishing work on the driving wheel. This tyre is supplied for machines fitted with round rims only.

Stand No. 6.
The R.O.M. Tyre and Rubber Co. (1909), Ltd., 35 and 36, Brooks Street, Holborn, London, E.C.

A PLEASING variation of tyres to suit all types of motorcycles, from the lightweight to the heavy sidecar machine, is to be found on the R.O.M. stand. The R.O.M. Co. particularly advocate their oversize tyres for passenger machines, much trouble having been experienced in the past with rear driving covers which were too light and small in section. One of the most interesting among the exhibits is the R.O.M. combination non-skid tyre, which is advocated to render the machine practically free from punctures, being, at the same time, "skid proof." The heavy tyres for flat-base rims, 700 mm. by 80 mm. and 650 mm. by 65 mm., are worthy of note. The R.O.M. rubber stud non-skid and rubber car covers are very serviceable-looking, all-rubber non-skids, with attractive treads and at moderate prices.



Top (left to right) : Bates, Hutchinson Passenger, Thames, R.O.M. Bottom : John Bull, Clincher, Goodrich.

Stand No. 90.
The North British Rubber Co., Ltd., 257-259, Oxford Street, London, W. 1.

THE North British Rubber Co.'s stand contains a selection of tyres for every type of vehicle. The Dreadnought passenger extra heavy tyre has a particularly strong tread, and is very suited to sidecar work. The Deluxe extra heavy rubber non-skid and the Deluxe heavy are both suitable for heavy motorcycle use. Tyres for lightweights are the Junior Deluxe rubber non-skid and the Dreadnought three-ribbed. Clincher Flexis motorcycle belts are also exhibited.

Stand No. 125.
The B. F. Goodrich Co., Ltd., 117-123, Golden Lane, London, E.C.

THE Safety Tread Goodrich tyres which are on show at this stand are made from the same rubber and cotton fabric as the famous safety tread motor tyre, and possess the same perfect balance and resiliency. These tyres are some of the strongest of their kind on the market, and are eminently suited for sidecar work. Goodrich rubber solution and vulcanizing compounds, such as used in the manufacture of the tyres, are also on show. Gas tubing for lighting sets and reel hose for garage use is also worth examination. The former are exhibited in all sizes in red and black. The hose is of the two-braided construction variety, and is extremely durable, and cannot kink. It is obtained in any length up to 250 ft.

Stand No. 89.
The Leicester Rubber Co., Ltd., Post Office Place, Leicester.

HERE we find a profusion of everything made of rubber, useful to the motorcyclist, including John Bull compressed rubber tyres in ribstud and cross-groove tread, in various sizes up to 650 mm. by 70 mm. by 65 mm. and 28 in. by 3 in. for American heavy passenger outfits. The John Bull tubes are made from the finest Para rubber, and their Tourist Trophy, a tube of double thickness, is attractive to those riders who find the average tube insufficiently stout for their needs. The John Bull deep-drive belts, which helped Pullin on the winning Rudge in the last T.T. to achieve his victory, are claimed by the company to have increased driving surface and greater gripping powers than any other belt. John Bull compound and sticky patches are exhibited and demonstrated, some well-equipped repair outfits are shown, also the John Bull strip patches, which are purchased in a roll and cut off as required.

The Mend-a-Tear outfits, indubitably the most satisfactory method of repairing motor-cycling waterproofs, are shown and explained to those interested.

In addition to all the above, visitors will find footrest rubbers, clipping gaiters for outer covers, pedal rubbers, insulating tape, retreads for motorcycle tyres, valve seatings, overalls, handlebar grips, horn bulbs, and a host of other things too numerous to record.

Wood-Milne, Moseley, and Palmer Tyres.

Stand No. 129.
Wood-Milne, Ltd., and George Spencer, Moulton and Co., Ltd., 42, 44, 46, Wigmore Street, London, W. 1.

AT stand No. 129 are to be seen exhibits of the Wood-Milne motorcycle covers, tubes, and belts. Among the covers, an interesting exhibit is the Keygrip, a popular racing tread, which is shown in two patterns, three-ply and four-ply. A heavier cover is on view in the form of the Four-ply Combination; this steel-studded tyre is specially advocated for reliability and lasting wear. Motorcyclists who have suffered from excessive belt trouble will find on Stand No. 129 an article worthy of notice in the Wood-Milne motorcycle belt, specially designed to overcome this hugbear of all-weather riders. Wood-Milne motorcycle tubes to fit the covers referred to above are also on view.

Stand No. 137.
Moseley, David, and Sons, Ltd., 19-20, Holborn Viaduct, London, E.C. 1.

TWO items in this exhibit are of particular interest to motorcyclists. One of these is the Moseley heavy motorcycle tyre for medium-powered machines up to 6 h.p., which is of the three-rib-tread variety. This tyre has a foundation of a special weave heavy motor tyre-canvas of three or four plies, according to the size. The other is the Moseley rubber-studded motorcycle tyre, which is suitable for lightweight motorcycles of two strokes, up to 3 h.p., with or without sidecars. This tyre, although designed for light work, is made of full thickness extra tough grey rubber, and has a foundation of three plies of heavy woven canvas. A complete range of cycle and motorcycle tyre accessories is also shown.

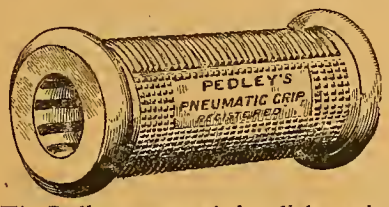
The three-rib Moseley motorcycle cover.

Stand No. 182.
Patchquicks Patents, Ltd., Tiverton, Devon.

THE Patchquick exhibits at Stand No. 182 will include samples of the famous tyre patches, made in numerous sizes and shapes to suit every puncture or burst likely to occur, together with the special Fix to be used in conjunction with the patches. The complete tyre-repairing outfits, containing patches, tube of Fix and other necessities, will also be on view.

Stand No. 45.
Pedley, J., and Son, Ltd., Oxford Works, Gt. Charles Street, Birmingham.

ON this stand a full range of the articles manufactured by J. Pedley and Sons, Ltd., is exhibited. The well-known Pedley three-rib heavyweight motorcycle tyre is shown, as is also the inner tube, the Pedley belt, and specially prepared tyre patches. An item of interest to all motorcyclists is the pneumatic handlebar grip, which is so constructed as to prevent almost all vibration on the handlebar from being transferred to the rider's wrists and arms.



The Pedley pneumatic handlebar grip.

Stand No. 9.
Capon, Heaton and Co., Ltd., Hazelwell Mills, Stirchley, Birmingham.

A GREAT variety of tyres and tubes is found on this stand, all sizes being shown and various pattern treads. Everything, in fact, for the rubber equipment of the motorcycle is shown, handlebar grips, footrest rubber pads, footboard matting.

Stand No. 160.
Surridge, R., 73, Church Street, Camberwell, London, S.E. 5.

IN addition to the well-known Holdtite tyre patches and repairing outfits, Messrs. Surridge's Patents are showing two interesting novelties at their stand.

All users of lighting apparatus other than electric will be interested in the new design of aluminium rear and sidecar lamps which, it is claimed, are immune from accidental blowing out. Another useful patent is shown in the form of a novel design of head and rear bag connectors. A full range of Holdtite specialities is exhibited, also patches, solution, inflators, belts, overall suits, etc.

Stand No. 4.
Clipper Tyre Co., Ltd., 52-60, Steelhouse Lane, Birmingham.

ON this stand are shown the well-known Clipper motorcycle tyres. These are made in two models, the ordinary Clipper for average weight motorcycles and the Reflex-Clipper Ideal tyre, which is specially constructed to meet the requirements of high-powered engines. Motorcycle tyre repair kits are shown, including the Silent outfit, which is supplied in a leather roll.

Stand No. 111.
Cuthbe, Chas. L., and Co., 37, Gt. Eastern Street, London, E.C. 2.

THE Max Cycar tyre is of a particularly sturdy nature and very suitable for sidecar work. The Max End-to-End and lightweight tyres are also exhibited.

Stand No. 8.
Midland Rubber Co., Ltd., Ryland Street, Birmingham.

A VARIED array of goods will be exhibited by the Midland Rubber Co., who earned a reputation as rubber manufacturers before motorcycles were considered practicable machines. Foremost amongst the motorcycle tyres is the Britannic and Studded tyre, and this is followed by the Midland, which is made in three types—ribbed, grooved, and studded. In addition to tyres, several small rubber accessories of interest to motorcyclists are exhibited.

Stand No. 133.
Macintosh, Chas., and Co., Ltd., 22-23, Jewin Street, London, E.C.

A FULL range of motorcycle tyres is exhibited at this stand. The Chain pattern cover is worthy of note, and is made of best Egyptian canvas and best quality rubber. This particular tyre is made in all the usual sizes.

Stand No. 112.
Palmer Tyre, Ltd., 119, 121, 123, Shaftesbury Avenue, London,

THIS exhibit comprises Palmer motorcycle tyres of varying grades, Palmer two-ply tyres for sidecar use, and the Palmer Scooter tyre. No particular change of programme is indicated by the Palmer tyre display, but certain grades of the tyres shown are identical with those used by winners of numerous trials and competitors during the past year. It is noticeable that the requirements of sidecar users are now fulfilled by Palmer two-ply tyres, instead of the sidecar tyres which were hitherto advertised. An interesting and novel feature of the exhibit is the Scooter tyre, the demand for which has been enormous.

The well-known Palmer cord tyre.

Stand No. 132.
Self-Sealing Rubber Co., Ltd., Ryland Street, Birmingham.

THE well-known Hermetic specialities are on view, and amongst other exhibits are seen the specially moulded heavy motorcycle tyres known as the Hermetic Peerless. Three other grades of Hermetic tyres are also exhibited, and the Fixkwik compound patches for tubes and tyres. Everything relating to tyres is to be seen, including repair outfits, plasters, gaiters, and repair bands. Horn bulbs and motorcycle belts of all sizes are also shown.

SECTION 8.—Lubrication and Tank Fittings.

Stand No. 221.
The Anglo-American Oil Co., Ltd., 36, Queen Anne's Gate, London, S.W. 1.

ALL grades of motor spirit, together with illuminating oils and fuel oils, are exhibited at the Anglo-American Oil Co.'s stand. Of special interest to motorcyclists will be found Pratt's Perfection spirit, in the familiar green can, the standard grade of motor spirit for all classes of motor vehicles, and Anglo's Benzole, a very popular fuel. Victory Spirit, a well-balanced petrol-benzole blend, is another interesting feature.

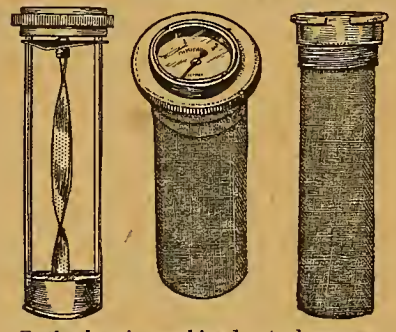
Stand No. 181.
Challenge Oil Co., Ltd., Howard Works, Howard Road, Stoke Newington, N.

THE Challenge Oil Co. are exhibiting a good variety of motor oils for air-cooled and water-cooled engines, all types of greases, carbide, petroleum jelly, French chalk and many lubricants.

Stand No. 171.
Price's Co., Ltd., Belmont Works, Battersea, London, S.W. 11.

AT Messrs. Price's new stand, No. 286, is to be found a comprehensive range of the oils produced by this concern to meet the varying conditions of internal-combustion engines of all types.

Among the exhibits are shown such well-known brands as Motorine, Huile de Luxe, Hub Lubricant, Oleogene, Belmogene, etc. Messrs. Price's are exhibiting a novelty in hub lubricants, entitled Hub Lubricant Stiff. This material, of a new grade, is particularly suitable for use in motorcycle ball bearings where it is required, not only for lubricating purposes, but also to act as a preventive to the admission of water, mud, and dust. It is also advocated as admirable for leaf springs, whether exposed or enclosed.



Rotherham's combined petrol gauge, filter and filler, to be seen at Stand No. 214.

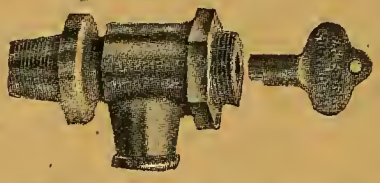
Stand No. 141.
Vacuum Oil Co., Ltd., Caxton House, Westminster, London, S.W. 1.

LUBRICATION requirements of all makes and models are provided for at the Vacuum Oil Co.'s stand.

Riders requiring a light-bodied oil are recommended to use Gargoyle Mobiloil "A," the "B.B." grade has a heavy body, while "B" serves where an extra heavy oil is required. The "T.T." grade is designed for use in racing machines. Besides these varieties there is on exhibition the Gargoyle clutch oil and Mobilubricant, a medium-bodied grease, freed from particles, for covering chains, packing wheel hubs, and similar purposes. Motorcyclists visiting the stand are recommended to ask for a copy of the new edition of "Correct Motorcycle Lubrication," which, besides technical information and advice upon the subject of lubricants, contains the company's chart of recommendations applicable to all their makes.

Stand No. 167.
Wakefield, C. C., and Co., Ltd., 30-32, Cheapside, London, E.C.

A FULL selection of standard Castrol motor oils and greases will be on show at this stand. This will include the celebrated Castrol R, the lubricant used on each of the transatlantic flights. Castrol Gearcase and Castroleum will be among the greases exhibited. The patent locking tap suitable for both drums and barrels is of particular interest. All Castrol drums and barrels are now supplied fitted with a hermetically-sealed aperture in which the patent locking tap is inserted. No cutter is required and one tap will serve any number of barrels or drums. Only the one size of tap (⅜ in. bore) is needed for both receptacles. The tap is simply inserted in the aperture and screwed home by hand in a few seconds. The present price is 5s. 9d., and it can be obtained from all Castrol agents.



Wakefield's locking tap for oil drums and petrol barrels.

Stand No. 149.
Coventry Movement Co., Ltd., Spon Street, Coventry.

THIS company provides a display of screws, studs, ball joints, nuts, grease cups, brass taps, etc., of excellent finish. Their patent spring-lid lubricators are shown in all sizes from the smallest to a monster 8 ins. in diameter, which they jestingly affirm is intended for magneto bearings. One of the most interesting features from the motorcyclist's point of view is their petrol or oil-level indicator. It comprises a cork float having an up-and-down movement, held in place by a tube passing through its centre. Inside is another tube having a spiral slot, which causes a turning movement as the float falls and rises with the level of the liquid in the tank. Fixed to the spirally-cut tube is a white disc, the relative position of which shows the amount of petrol or oil through a glass on the tank top. It is undoubtedly a great convenience to be able to see at a glance the amount of petrol in the tank, and the number of indicators in the Show, of which this is a typical example, is a sign of the times.

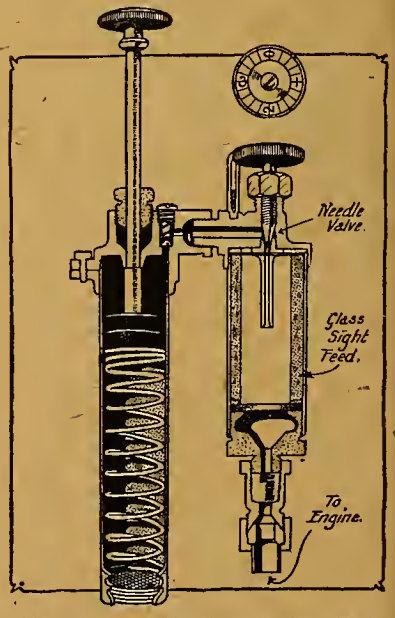
Stand No. 203.
Best and Lloyd, Ltd., Cambray Works, Handsworth, Birmingham.

THE semi-automatic drip feed, now so popular on motorcycles of all sizes from two-strokes to big twins, is to be seen here, and interest centres in the new mechanical oil pump, which is designed to work in conjunction with it.

The Coventry Movement Co.'s petrol or oil indicator.

This we recently described, and it may be remembered that an ingenious reduction gear of 60 to 1 drives a small pump plunger which takes in and delivers oil through the valves of the hand pump. The chief advantage is the elimination of the human element, and the provision of a regular and constant flow of oil to the engine. The adjustable stroke of the pump makes it suitable for all conditions of engine load, and it may even be connected to the throttle if so desired. Other interesting exhibits are tank fittings of many varieties, glass-topped filler caps, screw and bayonet joint filler caps, petrol gauges and filters, petrol taps for one, two or three-ways, everything, in fact, for the convenience of the rider as applied to petrol tanks.

This concern is one of the best known in its own particular sphere of activity, and visitors should make a point of inspecting this representative stand, particularly the mechanical oil pump described in the foregoing.



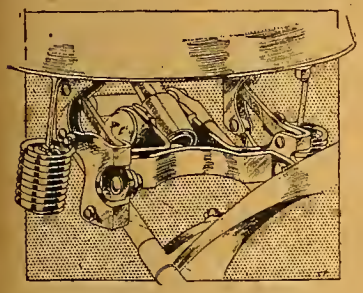
The Best and Lloyd hand sight-feed oiler.

SECTION 9.—SADDLES AND OTHER LEATHER GOODS, etc.

Stand No. 236.

Brooks, J. B., and Co., Ltd., Great Charles Street, Birmingham.

J. B. BROOKS AND CO., LTD., have always specialized in saddles, and this year several types are exhibited. Most of them are fitted with the well-known Brooks compound spring, but the B220 has laminated springs, anchored in the centre, and giving free movement at either end of the spring. This saddle is particularly suitable for spring-frame machines, or for riders who require a low seat position for speed work. Another saddle particularly recommended is the B400 type, which is made with springs of several different

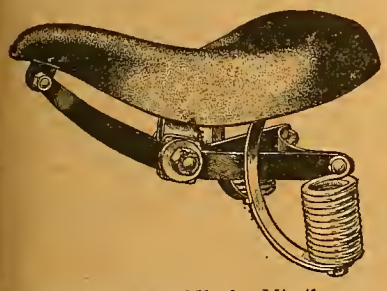


The Brooks B400 saddle.

strengths, to suit riders of varying weights.

Various tool and carrier bags are shown, including the Brooks motorcycle carrier bag. The outside dimensions of this are 16½ ins. by 10½ ins. by 6½ ins., and it is made in two parts, the outside part being permanently fixed on the carrier. The inner case and its contents are thus kept dry and free from dust, and when required can easily be removed.

The Brooks spring-on leggings are also exhibited. These are made in various sizes, and they can be clipped on, or removed, in a few seconds—a fact which everyone who has struggled out of the ordinary type at the end of a wet ride will much appreciate.



A well-sprung saddle by Middlemore and Lamplugh.

Stand No. 138.

Middlemore and Lamplugh, Ltd., Little Park Street, Coventry.

THIS stand, while catering very largely for cyclists, has upon it a great deal to interest motorcyclists. The Lamplugh saddles especially have been known for many years past, and visitors will do well to inspect the merits

The Brooks spring-on leggings are very easy to remove.

of the motorcycle saddles Nos. 970-1 B and 975-6 B. Two very businesslike tool bags are shown, one being metal covered and having straps in addition to its spring fastener and lock. The strap undoubtedly relieves the lock from a certain amount of strain, more especially so when the bag is rather full, which usually happens early in its career. The mudguards have deep valances on the front, and an extension piece at the edge of the rear one, are well finished and fitted with stays of stout gauge.

One of Tan-Sad's pillion seats.

Stand No. 229.

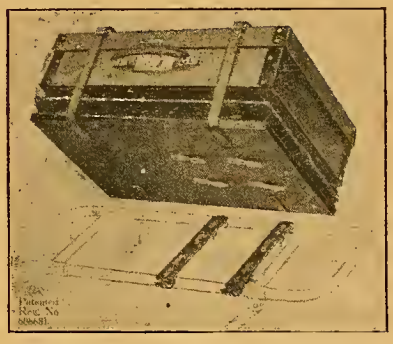
Leatheries, Ltd., Sampson Road North, Sparkbrook, Birmingham.

MOTORCYCLE saddles, pannier bags, belt and tube cases, back rests, fixed and folding, carbide carriers, plug cases and carrier touring bags, are shown on this stand. All of them are made of the best materials, and are listed at competitive prices.

The saddles exhibited are the Nos. 73,

A tube and belt case by Leatheries.

87, and 91. These incorporate the company's patent double hangers, shock absorbing links, and pressed steel anatomical bases. The models comprise a suspension seat, which yields to the rider's weight along its entire length, independently of the under frame. Any vibration or shock is absorbed before it can reach the rider, whilst any tendency towards bouncing is eradicated, even on the roughest roads.



A Leatheries bag for attaching to the carrier.

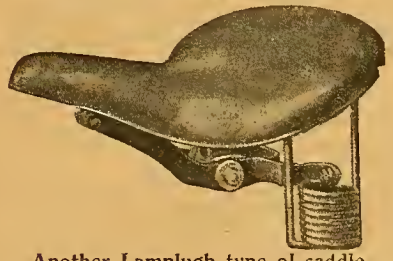
Stand No. 211.

Tan-Sad Works, 9, Freeman Street, Birmingham.

PILLION riding is a much debated practice, but undoubtedly any risk is greatly lessened when the passenger is provided with a comfortable seat. The Tan-Sad seat is well known, and it is shown on this stand in various forms, with back rest, foot rests, tool bag carrier, petrol can carrier, etc., all built up round the central idea.

A further development is a saddle which fixes to the carrier of the machine. The pivotal point is placed as far behind the rider as possible, and six coiled springs are utilized for the suspension. This combined saddle and pillion seat is claimed to provide all the advantages of a spring frame.

This saddle is also shown with a collapsible back, which can be raised by the



Another Lamplugh type of saddle.

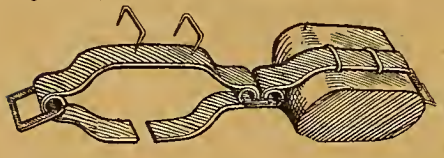
rider when on the machine, and a further development is a footboard attachment by means of which the feet are sprung in conjunction with the saddle. A new departure for the Tan-Sad works is a rear lamp combined with a number plate in one piece, thus avoiding all chances of the lamp working loose through vibration. The burner is mounted in a slide held by a spring and connected to the lamp top, which can be raised to expose the burner when lighting-up time comes.

Saddles continued—The Chain Association's Work.

Stand No. 183.

Lycett Saddle and Motor Accessories Co., Ltd., Bromley Street, Birmingham.

ON this stand are shown various models of the well-known Lycetts La Grande saddles. The manufacture of the ordinary type belts has been discontinued, and a new rubber link belt has been introduced in place, the main features of which are shown clearly in our illustration. The body of the belt is composed of V-shaped pieces of solid rubber. Round the centre of each piece is a spring steel clip, which is attached by means of two small staples on the top. These clips are held together by links, which cannot become detached



A novelty in belt construction—the Lycett rubber link.

unless the staples and the rubbers are removed. Flexibility is obtained by means of the spring clips, and as the main wearing part of the belt is composed of solid rubber, almost indefinite life should be assured.

The saddles are on similar lines to the 1919 productions. A very interesting feature is that they are hinged at the front and at the top of the rear tension springs. By this means a straight pull action is obtained.

Stand No. 208.

Gough and Co., 180, Park Road, Hockley, Birmingham.

GOUGH productions do not differ to any great extent from those which have been on the market during 1919. There is, however, one innovation in the form of a patent leaf spring saddle, which gives a very low and comfortable riding position. The well-known Gough semi-pan seat saddles are shown, as are the company's usual range of leather toolbags, tube and belt cases, carbide carriers, and the like.

Stand No. 219.

X-L-All, Ltd., Hall Green, Birmingham.

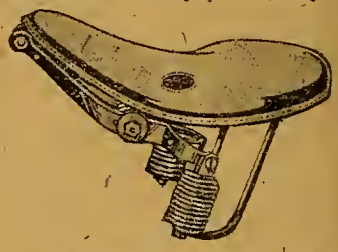
VARIOUS types of the well-known X-L-All saddle and two types of sparking plugs are shown on this stand. The 1920 saddles are designed on particularly substantial lines, and embody several special refinements. The underwork of the saddle is constructed in steel, and the various fitments which were previously riveted are now acetylene-welded to the main portion. All the types are of the parallel-spring motion with the exception of model S2, which is designed to meet the demand for a comfortable saddle at a low price. An innovation is a folding back rest, which, when not in use, can be folded over the saddle, completely covering it. This should be most useful in wet weather.

The well-known X-L-All detachable plug is shown. Large insulating porcelains and adequate cooling fins are provided, and the upper portion can be removed for cleaning purposes when required and screwed back without the position of the centre electrode being disturbed. This model retails at 6s., and the X-L-All standard non-detachable plug, which is suitable for all ordinary purposes, at 3s. 6d.

Stand No. 223.

Wilby, A. E., Ltd., 113-115, Holloway Head, Birmingham.

A COMPLETE range of Wilby saddles and other leather goods for motorcycles are shown on this stand. The sound yet simple design and substantial construction are worthy of note, only the



For lightweights—The Lycett No. 6 saddle.

finest materials being employed. Pannier bags in many different shapes and sizes are also exhibited, the strong flaps being a commendable feature. The importance of a strong pannier bag for the retention of the tool kit is highly necessary, and one has only to glance at the dilapidated pannier bags of an old machine and then at the latest examples as shown on this stand to realize the strides that have been made in this and similar directions.

CHAIN TRANSMISSION.

Stand No. 179.

Association of British Driving Chain Manufacturers, Bassishaw House, Basinghall Street, London, E.C. 2.

AS the various manufacturers of driving chains are exhibiting specimens of the new standard sizes at their respective stands, literature only is to be found at the stand of the Association of British Driving Chain Manufacturers.

Stand No. 155.

Alfred Appleby Chain Co., Ltd., Whitwork Works, Tilton Road, Birmingham.

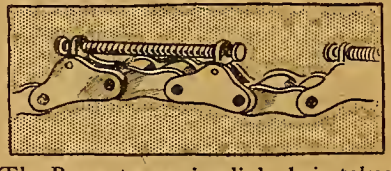
ON this stand is shown a full range of motorcycle chains, stamped steel pressings, frame lugs, fork crowns, etc., used in the manufacture of motorcycles. The well-known Alfred Appleby and Atco roller chains are prominent.

Stand No. 190.

Brampton Bros., Ltd., Oliver Street Works, Birmingham.

NOW that chain drive is becoming so popular, particular attention must be paid to the quality of the chains. On Messrs. Brampton Bros.' stand, all types of roller chains are on view, and in addition there are various sizes of the inverted tooth, or, as it is usually called, silent types. The latest Brampton chain is the "spring" type, which can be adjusted very tight, the springs being an excellent substitute for a shock absorber. Numerous models of motorcycle hubs, for belt or chain-driven machines, are also shown, including the patent dust-proof hub.

Five models of the Brampton Biflex spring fork may be seen; these are suitable for motorcycles from 2¼ h.p. to 10 h.p.



The Brampton spring-link chain takes the place of a shock absorber.

Stand No. 165.

Coventry Chain Co., Ltd., Spon End Works, Coventry.

ON this stand are photographs of the Coventry inverted-tooth chains. These include engine to countershaft, magneto, camshaft and lighting-set drives. This type of chain is slowly but surely coming to the fore on account of its silence, long life and kindness to sprockets. Among other concerns, the Rover and Matchless companies are taking the drive from engine to gearbox on chains of this pattern, in preference to the older and noisier roller variety.

Stand No. 192.

Renold, Hans, Ltd., Burnage Works, Didsbury, Manchester.

SOME examples of countershaft and rear drives are exhibited, suitable for all powers—from lightweights to 9 h.p. models. The countershaft drive for the heavier models is of the inverted tooth (silent) type, with segmental bush bearing. This chain is of new design, and provides a greater bearing area, together with improved bearing surface, than any previous design. The construction of this bearing permits of extreme accuracy of pitch and, as the full bearing area is utilized the moment the chain is put into service, a longer chain life is assured.

Self-contained means of lubrication, maximum bearing area, minimum weight of chain for given bearing area, and improved bearing surface, are outstanding features of the above chains. The rear drive chains are of the roller pattern, and, by the use of special alloy studs and heavier links, the minimum breaking strength is increased by 50 per cent.

SECTION 10.—SPEEDOMETERS.—Watford, Cowey, Bonniksen, Jones, Stewart, and Smith.

Stand No. 210.

North and Sons, Ltd., 14, Soho Square, London, W. 1.

ONLY two models of the well-known Watford speedometers are on exhibit at the makers' stand. Model 42 is a black finish, nickel-plated bezel speedometer, priced at £5 5s. The dial is black with white figures and indicates speeds up to 60 m.p.h., the total mileage counter running up to 10,000, when it repeats. A quickly reset trip counter up

The Watford.

to 100 miles, showing tenths, is incorporated with this model. Model 40, priced at £4 15s., corresponds in all details to the former, with the exception of the trip counter, which is not supplied with this model.

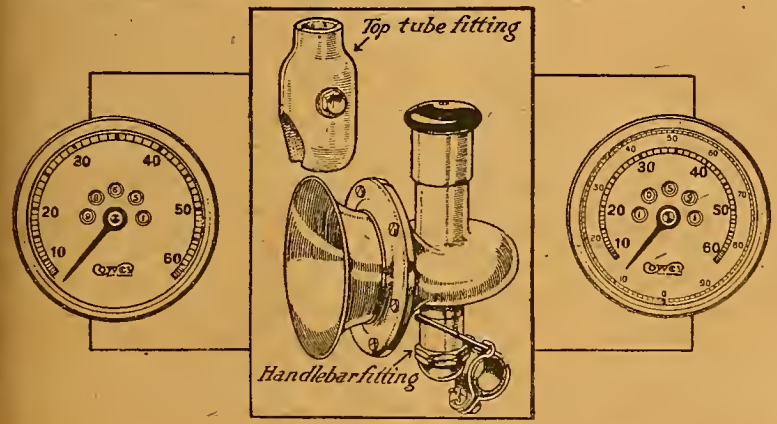
Stand No. 196.

Cowey Engineering Co., Ltd., Archer Works, Kew Gardens, Surrey.

VARIOUS models of Cowey speedometers and mechanical horns are on exhibition at Stand No. 196. Model B speedometer, finished in nickel or black according to taste, indicates speeds from 5 to 65 m.p.h., and is priced at £4 15s. Model B.T. is identical with model B, but has the addition of a trip counter. This model is priced at £5 5s. Speedometers calibrated to 80 m.p.h. may be obtained for 10s. extra.

One model only of Cowey mechanical horns for motorcycles is on view; the model B, finished in nickel or black, and fitted with top tube or handlebar bracket as preferred. It gives a particularly loud and piercing note, and is priced at £3.

The Cowey Speedometers and Mechanical Horn.



Stand No. 175.

Markt and Co. (London), Ltd., 98-100, Clerkenwell Road, London, E.C. 1.

THE Jones speedometer (now under the control of the Johns-Manville Co.) is little altered from the original pattern, the only difference being a circular form of scale instead of the old Jones short arc. The speedometer reads up to 60 m.p.h. with total and trip mileage, but is without the old maximum-hand feature. There is no change to record in the Veeder cyclometer, save in price. The star wheel and striker type of motorcycle cyclometer is now 20s., and the Harley-Davidson model 32s. 6d. The gear-driven instrument with axle fitting is 35s.

Other items of interest are the Long mechanical motorcycle horns and the Delta electric lamp with top-tube battery. There is a large variety of wrenches, including the Mossberg revolving dome and Sterling rotary axle dome type.

Stand No. 184.

Rotherham and Sons, Ltd., Coventry.

Bonniksen Isochronous.

THE Bonniksen Isochronous speedometer is governed by a balance spring, as a watch, and is positively unaffected by vibration. Its dial is calibrated in miles up to 50 m.p.h., after which it repeats, thus its reading powers are actually unlimited.

Stand No. 215.

Cooper-Stewart Engineering Co., Ltd., 11, Broad Street, Bloomsbury, London, W.C. 2.

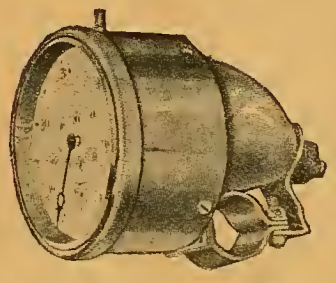
TWO MODELS OF THE STEWART SPEEDOMETER.

These can be obtained with or without trip mileage.

THIS season's Stewart speedometers are modelled more on the lines of their successful car type, which has a white dial. Two models are shown, No. 43, which is without trip and costs four guineas, and No. 42, incorporating a trip and priced at five guineas. These speedometers are for front-wheel drive only, and register from 5 m.p.h. to 60 m.p.h.

Stand No. 200.

Smith, S., and Sons (M.A.), Ltd., 179-185, Great Portland Street, London, W. 1.



Smith and Sons' speedometer.

THE new Smith speedometer is a great improvement on the pre-war model. The dial has been entirely redesigned, giving a perfectly clear reading, while the hand is claimed to be as steady as a clock hand at all speeds. The speedometer, which can be obtained in nickel or black finish, is priced at £4 10s., including the drive.

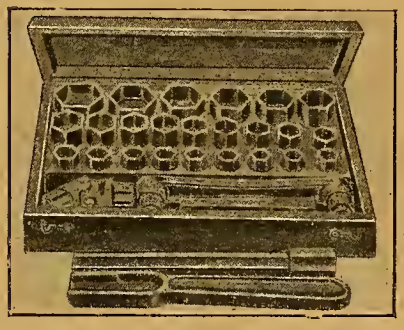
Some particularly well-made mechanical horns are shown, which are extremely strongly made and will withstand the hardest wear. They are supplied in ebony or black enamelled finish at £1 15s. or with nickel-plated trumpet at £2 7s

SECTION 11.—MISCELLANEOUS ACCESSORIES: A New Sturmey-Archer Gearbox.

Stand No. 163.
Sturmey-Archer Gears, Ltd., Lenton, Nottingham.

THERE is always a number of visitors to the Show specially interested in the Sturmey-Archer exhibit, for, though they are mostly well acquainted with the outside of the Sturmey-Archer gearbox, only a comparative few of them have had an opportunity of examining the internal mechanism and thereby finding out the how and why of the gear itself.

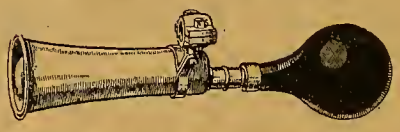
At the stand there are shown the three-speed countershaft gear and the two-speed countershaft gear for motorcycles. Each of these gears is sectionized to show the working parts, and very little explanation is required for anyone of a mechanical turn of mind to grasp the method by which the gears work.



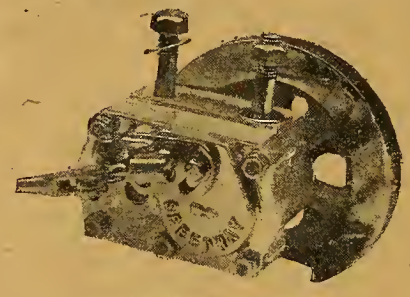
Lake and Elliott's Millennium box spanners.

The three-speed countershaft gear, which has done such wonderful work in every battle area during the war, is perhaps too well known to make any long description necessary. The only slight alteration that has been made recently is in the control, which is now carried on the down tube just underneath the tank, and is protected from wet, mud, etc. It consists of a circular disc, on the face of which are cut V-shaped notches which correspond to the gear positions. Another circular disc having similarly-shaped projections machined on its face is held in position in the notches mentioned by means of spring pressure. This disc is securely fastened to the long gear lever which takes up a horizontal position in bottom gear, along the tank, and is thus more conveniently placed than the old gear lever carried on the box itself. The lever can be set in different positions to suit individual taste.

On the new control the levers actuating the gears are made longer than on the old type, so that wear on the pin joints will not affect the positioning of the gears to anything like the same extent as obtained with the old control. Arrangements have also been made internally in the gearbox to allow a greater latitude between the gears in the neutral position. The gearbox itself is much neater and can easily be kept clean. Interest will be specially centred in the new two-speed countershaft gear, which is intended for use on lightweight motorcycles. The main principle in this is similar to the three-speed, the gears being in mesh all the time, and the change being effected by sliding dogs.



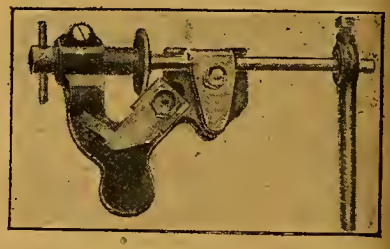
Lucas straight pattern horn.



The Speedway gearbox.

Stand No. 142.
Lake and Elliott, Ltd., Albion Works, Braintree, Essex.

SOME very useful tools for the use of repairers or the man who is lucky enough to have a well-equipped private garage are shown. A Universal valve truer for the facing up of badly-pitted valves, also a cutter for the valve seatings are very interesting. Valve spring lifters and gudgeon pin removers are two other useful tools. The keen rider will also be interested in the tools and appliances which are used in the manufacture of his machine, such as wheel truers, spoke cutters, and screwing machines, all of which may be seen.

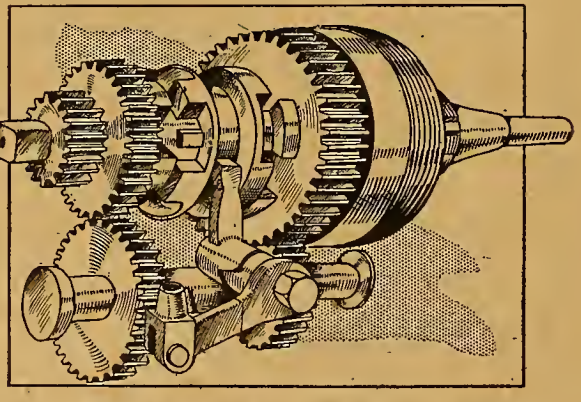


The Universal valve truer.

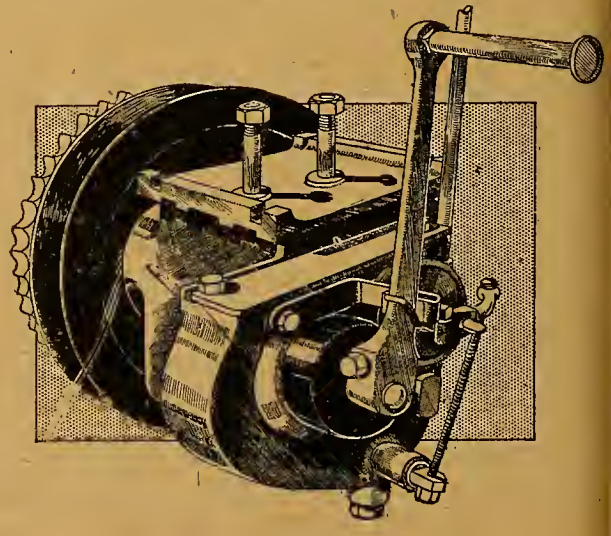
Stand No. 225.
Dover, Ltd., Northampton.

A NOVELTY here is the Dover warning signal, introduced to prevent the needless stoppage of kindly-disposed drivers under the impression that a car or motorcycle merely held up for a few minutes requires assistance. This device consists of one triangle displaying the letter R (resting), with another showing D (disabled), and, according to which is displayed, the passing driver knows definitely if he should stop. Normally, both triangles fold back out of the way, and fittings are supplied for motorcycles as well as cars.

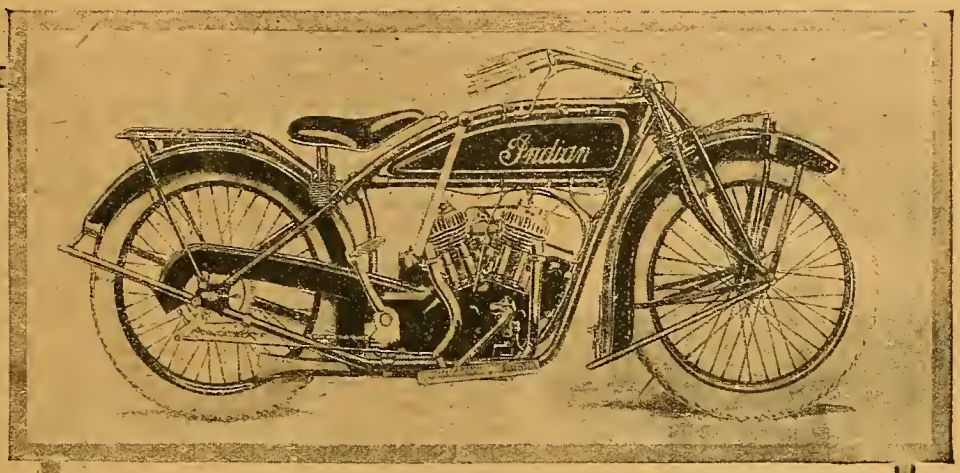
Another item, interesting in these days of electric lighting, is an accumulator repair outfit, while the company's pumps, grips, gear handles, etc., should be noticed.



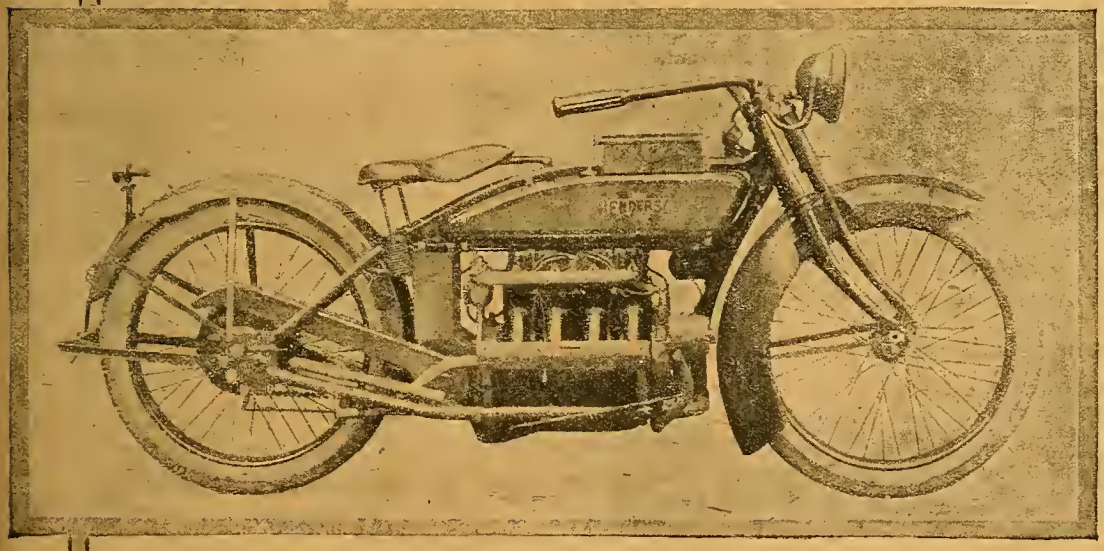
The gearwheels and dog clutches of the two-speed Sturmey-Archer and (right) the complete box.



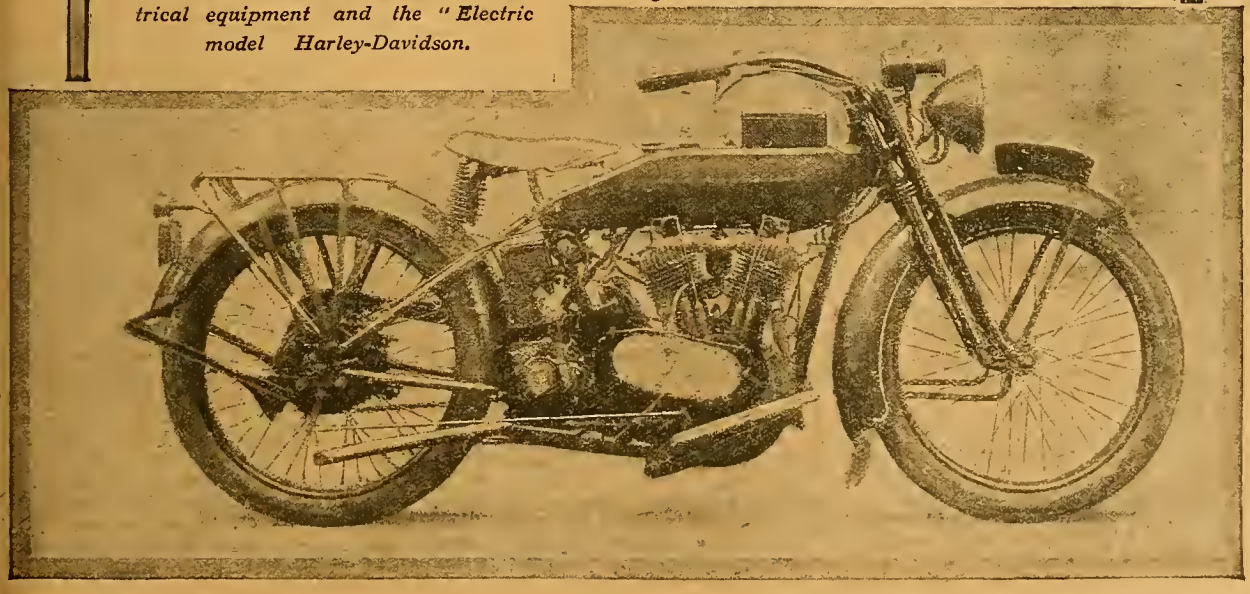
THREE POPULAR AMERICAN MACHINES.



The sports model 4 h.p. Indian which has gear and chain drive.



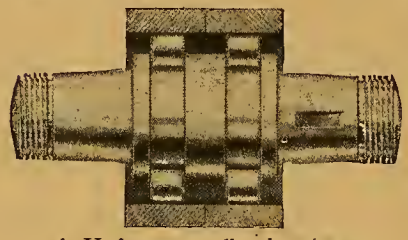
The four-cylinder Henderson with electrical equipment and the "Electric model Harley-Davidson.



SECTION 11.—MISCELLANEOUS ACCESSORIES: The Lamplugh Throttle-controlled Oiler.

Stand No. 235.
Hoffman Manufacturing Co., Ltd., Chelmsford, Essex.

A COMPLETE range of the standard sizes of ball and roller bearings and steel balls and rollers is exhibited. Special prominence has been given to those sizes and types which are most suited for use in the construction of motorcycles.



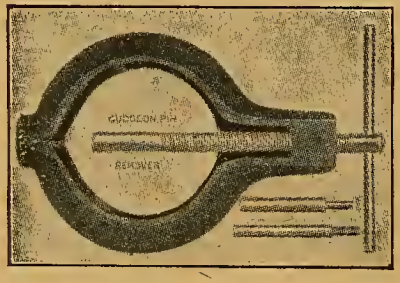
A Hoffmann roller bearing.

Stand No. 158.
Davenport, G., and Co., Ltd., 99-105, Clerkenwell Road, London, E.C. 1.

A LARGE range of accessories is on show here, including driving mirrors, watches, and cases for fitting to the handlebars, goggles, and a lighting and ignition dynamo. There are also several new designs in mileage recorders and speed indicators.

Stands Nos. 186-88.
Dunhills, Ltd., 359-361, Euston Road, London, N.W. 1.

THREE important new sidecar chassis are on show here, one suitable for featherweight sidecars, one specially constructed for touring purposes, and a very strongly-made article which is designed to carry a large coachbuilt body, suitable for two adult passengers and luggage. A selection of touring lightweight and two-seater bodies is displayed; also windscreens, triple or single, with



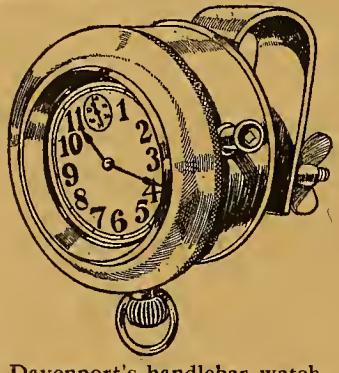
Lake and Elliott's gudgeon-pin remover.

polished walnut frames and celluloid windows with brass or nickel fittings. There is also a selection of motor-cycling clothing, which includes waterproof, leather and tweed jackets, also caps, gloves, leggings, goggles and handlebar muffs, many of which were described in our Winter Equipment Number. In the way of accessories there are lamps of all descriptions, mechanical and bulb horns, and many other accessories of a useful and practical description.

D64

Stand No. 176.
Lombard Rim and Tube Co., Lombard Street, Birmingham.

COMPONENTS for the manufacture of motorcycles and sidecars are seen on this stand, and possess many points of interest for the man who takes an intelligent interest in his machine and likes to know how it is manufactured. Rims for wheels are on view of various types, and one interesting pattern is seen to have specially formed depressions to accommodate the heads of the spoke nipples. This allows the nipples to bed down into the rim and lessens the possibility of trouble with inner tubes. Rims for scooters are also shown, and the family man may find even perambulator rims interesting. A large selection of handlebars is shown, and any type or shape can be obtained. Seat pillars, luggage carriers of all sizes and patterns, and back and front wheel stands, are some other specialities. Exhaust pipes of every shape and size appeal to the speed merchant.



Davenport's handlebar watch.

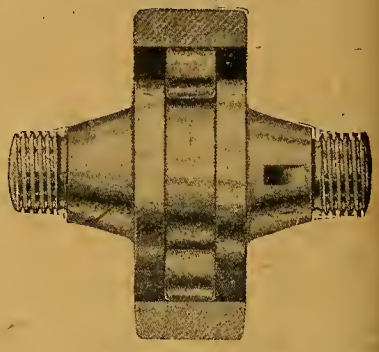
Stand No. 161.
Bluemel Bros., Ltd., Wolston near Coventry.

ONE of the most attractive exhibits here is the patent sidecar windscreen, which in design is far ahead of the average, offering very little resistance to the wind, at the same time thoroughly protecting the passenger by its curved edges and side panels. Instant fitting and detachability are two of its merits, and its sliding adjustment of 12 ins. to suit different passengers and varying weather conditions will be readily appreciated by those used to a rigid screen. Its finish and lines rather enhance the appearance of the sidecar than otherwise, and its weight is practically negligible.

The Bluemel pump is really too well known for comment, but we might remind readers that its barrel is steel lined to guard against warping if carried near a hot engine, and its substantial stirrup lessens the fatigue of inflating a large section tyre. Other interesting items are celluloid-covered handlebars and a large variety of grips, amongst these latter probably the "Autogrip," with a hook at its extremity, and the "Suregrip," fashioned to accommodate the fingers, are likely to make the strongest appeal to most riders.

Stand No. 218.
Bowden Wire, Ltd., Bowden Works, Victoria Road, Willesden Junction, N.W. 10.

AS usual, a very comprehensive range of this concern's productions are on show at their stand. Operating mechanism for all types of motorcycle brakes, gears and clutches are exhibited, also the Bowden extra air device.

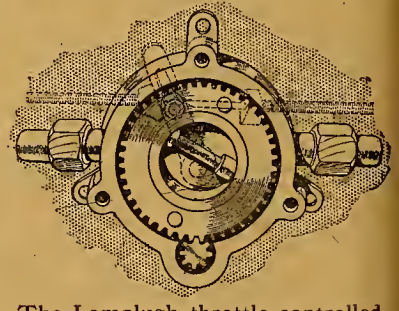


A Hoffmann single-cylinder big-end roller bearing.

Stand No. 173.
Lamplugh, S. A., Ltd., King's Road, Tyseley, Birmingham.

MESSRS. S. A. LAMPLUGH are showing a variety of petrol taps, compression taps, drain taps, etc., but their chief exhibit is the new throttle-controlled mechanical oil pump.

The body of the pump is made from an aluminium die casting, and is machined out to take a revolving drum, which also carries a double-ended plunger and a spur gearwheel. The drum is rotated by a spur pinion, which gives a reduction of about 7 to 1, and on the outside edge of the drum is machined a channel, into which the oil is alternately sucked in and pumped out by the double-ended plunger. The plunger is a sliding fit in



The Lamplugh throttle controlled lubricator.

the hole provided for it, and is machined across the centre to take the eccentric. The position of the eccentric controls the amount of oil that is delivered to the engine, the exact position being actuated by the throttle wire. When the throttle is closed, the position of the eccentric is such that no action is imparted to the plunger. As the throttle is opened, so the pump plunger throw is increased, and oil passes in proportion.

SECTION 11.—MISCELLANEOUS ACCESSORIES: Tubing and Fittings.

Stand No. 199.
Elephant Chemical Co., Ltd., 174-176, Neate Street, Camberwell, London, S.E. 23.

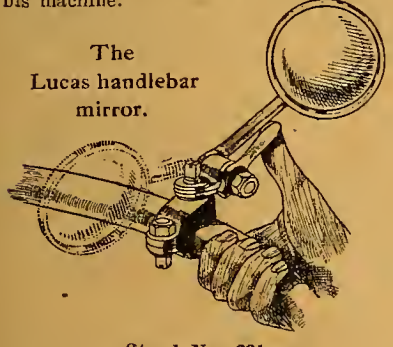
ELEPHANT specialities are well known for quality and reliability. A full range of their productions are on view, including oils, greases, enamels and products for the workshop, such as Brazine brasing flux, Caseardine compound and soldering fluxes.

Stand No. 170.
Coventry Plating and Presswork Co., Ltd., Raglan Works, Coventry.

THIS concern makes a good show of motorcycle petrol tanks of several sizes and in a variety of stages. Heavy and light steel pressings, brass spinnings, belt drums, carburetter floats, chain guards, and a host of other component parts of interest to the man who likes to compare details apart from the machine as a whole. Mudguards, bridges and stays are here in great profusion in patterns and sizes to suit every make of machine.

Stand No. 153.
Accles and Pollock, Ltd., Oldbury, Birmingham.

ACCLES AND POLLOCK, LTD., are exhibiting all types of steel tubing used in the manufacture of motorcycles. The tubing is shown in its plain form and also in single and double-butted tubing of the various components, such as steering tubes, handlebars, lugs, seat pillars, chain stays, fork blades, etc. There are also all types of box spanners. This stand cannot fail to attract the motorcyclist who takes an intelligent interest in the manufacture of his machine.



The Lucas handlebar mirror.

Stand No. 221.
Manufacturers' Accessories Co., Ltd., 85, Gt. Eastern Street, London, E.C. 2.

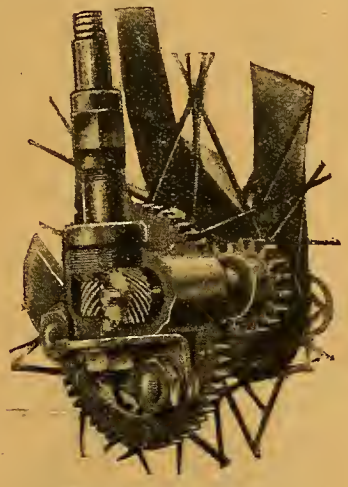
A LARGE number of accessories are on view at this stand bearing the familiar trade mark M.A.C. and M.A.C.O. The display is divided into three distinct sections: motorcycle fittings and accessories, tools and bicycle fittings. The motorcycle section embodies sidecar parts, hoods, windscreens, sidecar lamps, speedometers, tyres, clothing, etc., and a full complement of replacements, such as piston rings, washers, split pins, etc., and in the tool section pliers, twist drills, hand and breast drills, brazing lamps and garage appliances of types and sizes which should make a strong appeal alike to professional and amateur repairers.

Stand No. 157.
Stourbridge Rolling Mills, Ltd., Stourbridge.

THIS firm has on view samples of cold-rolled bright steel for press parts for motorcycle construction, together with specimens of pressings lent by their customers.

Stand No. 159.
British Hub Co., Ltd., Clyde Works, Weaman Street, Birmingham.

VARIOUS types of hubs are made by this company, and the majority of them are exhibited on Stand No. 159. The company has been obliged to abandon the manufacture of axles, steering heads, steering arms, etc., in order to concentrate on their hubs. Foremost of these are the "3B car hub," which has a width over flanges of 3¾ ins., and is drilled for 40 spokes, 10-gauge; and the "Motor hub No. 2" series, which is drilled for 36, 12-gauge spokes for front wheels and 40, 12-gauge spokes for back wheels.



The Jones speedometer drive. British agents are Markt and Co. (London), Ltd., 98-100, Clerkenwell Road, E.C.

Stand No. 144.
Kerslake, Ltd., Kyron Works, Deodar Road, Putney, S.W. 15.

AMONG the Kerco Specialities of interest to motorcyclists at Stand No. 144 are an all-brass tyre inflator and a patent duplicator for reproducing small drawings, tracings, and details, etc.

The makers state that they are capable of producing this inflator, a high-class, nickel-plated, all-brass solid drawn article, at the rate of 10,000 weekly, and they are exporting it to all parts of the world. The inflator is priced at 42s. Amateur designers will be especially interested in the Kerco Swiftograph Duplicator, a wonderfully simple machine, which is claimed to do all the work of a £25 article, with the same speed and efficiency. The duplicator is sold in box, with accessories complete, at £3 17s. 6d., quarto size, and octavo, £3 3s.

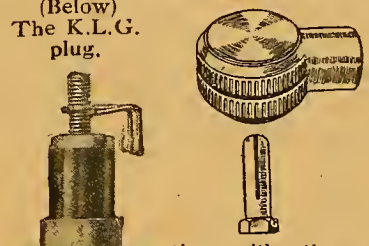
Stand No. 231.
East London Rubber Co., 29-33, Gt. Eastern Street, London, E.C. 2.

A FULL range of the well-known Kerry motorcycle goods is on exhibit at this stand.

The exhibits include Kerry motorcycle accessories in great variety, together with Kerry sidecars and chassis. Kerry tools, specially made for motorcycle work, are also on view, and in connection with these is shown a comprehensive range of stocks and dies. In the cover and tube line, all types of machines are provided for by such popular makes as Ideal, Saxon, Sterling, Celtic, County, and Duros. A feature of the exhibition specially of interest to all motorcyclists at the present time is the inclusive range of Kerry motorcycle wear suitable for all climates.

(Right) The Lodge quick detachable high-tension terminal.

(Below) The K.L.G. plug.



Stand No. 216.
County Chemical Co., Ltd., Chemico Works, Bradford Street, Birmingham.

A REPRESENTATIVE display of Chemico products contains, amongst other items, the following:—Chemico carbide and the useful leather case designed to accommodate a spare half-pound tin of carbide, rubber solution, tyre stopping, and complete repair outfits for tyres. Sunproof tyre paint will interest any demobilised men who have had experience of riding under an Eastern sun. Tyre repair bands and plasters, the well-known Chemico blow-out patch, Reliance patches, and all other tyre accessories and necessaries are also shown. Those riders who like to touch up any faulty enamel and preserve the appearance of their machines will find various enamels and the famous Robbialac of interest.

Stand No. 226.
Micrometer Engineering Co., Ltd., Spon Street, Coventry.

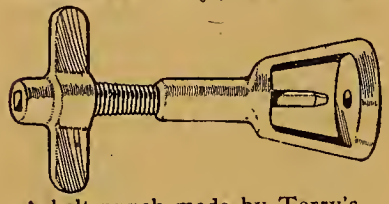
THE chief item of interest here is the company's patent Flexo waterproof motorcycle saddle, a novel feature of which is the waterproof flexible top absorbing all bounce and road shocks not taken up by the springs. This saddle top has a pleasing polish and is fastened to its frame without the aid of unsightly rivets. Sections and frames are exhibited showing its construction. The motorcycle size sells for 38s. 6d.

A Plethora of Useful Accessories.

Stand No. 232.
Ashby, Frank, and Co., Charlotte Road, Stirchley, Birmingham.

AMONGST a variety of fittings and small accessories is a very useful range of lamp brackets for use on either the machine or the sidecar. Brackets for the sidecar are not always easy to obtain, but whatever be the shape of the body there is sure to be a bracket to fit from amongst the selection on this stand. Three varieties are shown suitable for fitting to the coachwork, one of which is useful if it is desired to carry a lamp on the nose of the sidecar.

Another useful bracket is arranged to clip to a tube or spring. A fitting for which there should be a good demand is an adjustable bracket for carrying the tail lamp. It is arranged to bolt-securely to the carrier, and, being very substantial and of heavy gauge steel, it is capable of supporting quite a heavy lamp. The whole range of brackets are very solidly constructed and nicely finished in black.



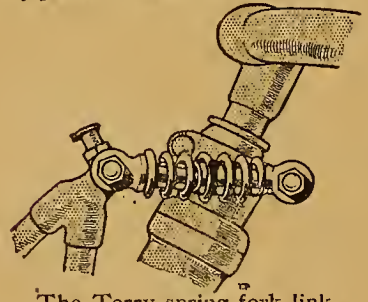
A belt punch made by Terry's.

Stand No. 185.
Terry, Herbert, and Sons, Ltd., Novelty Works, Redditch.

IT will astonish but few people to know that the valve springs which played their part in the famous Atlantic flight of R34 emanated from the house of Terry. Valve springs of all descriptions are seen on this stand, and in addition springs for every other purpose of a motorcycle.

A neat metal clip which supports the bulb of a horn and so prevents the rubber cracking through incessant vibration, a small wire brush for cleaning choked acetylene burners, and a novel set of tyre clamps which simplify the task of removing and replacing very stiff covers are cases in point.

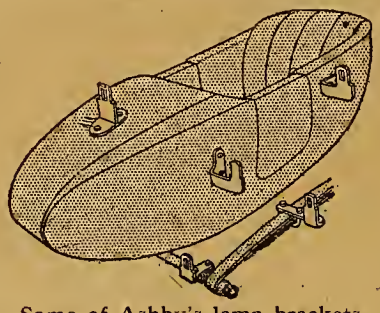
An ever useful set of spanners consists of five double-ended spanners for ⅛ in. to ½ in. Whitworth nuts. They are made of tempered steel and are very light and durable, the finish is plated or oxydized, and when complete with a small leather case they form an extremely neat set for pocket use, thus often saving the rider from unpacking his pannier bags and disturbing his carefully-packed tools and small spares.



The Terry spring fork link.

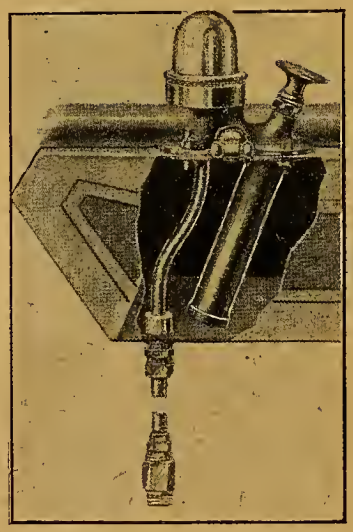
Stand No. 177.
Atkey, A. R., and Co., Ltd., Trent Street, Nottingham.

INTENSE interest centres round the Fault Finder exhibited here for the first time. By its aid it is possible for anybody, whether novice or expert, to



Some of Ashby's lamp brackets.

locate leakages and shorts in magnetos, dynamos, and, in fact, every conceivable form of electric appliance. Magnetos can be tested on high or low tension circuits, and it is equally useful applied to lighting sets in car or house. Demonstrations are held more or less continuously, and interest never seems to flag. The whole instrument is encased in a polished wood box, 18 ins. by 15 ins. by 6 ins., thus adding portability to its other merits. The company are in the happy position of being able to deliver this and their other specialities, including tools, spanners, etc., ex stock.



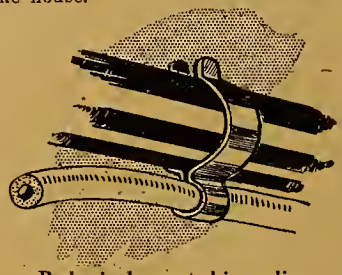
Enots sight-feed lubricator.

Stand No. 168.
Benton and Stone, Ltd., Bracebridge Street, Birmingham.

THE tank fittings which bear the trade mark "Enots" are well known, and are found in profusion on this stand. Seasoned motorcyclists will see all the well-known patterns of petrol taps, filler caps, etc., and, in addition, a few new patterns of considerable interest since they were largely called into being by the demands of the Air Force.

In particular there are some cork disc-seated taps which never leak and which never bind; the ease of manipulating them is wonderful. Quite the neatest petrol filter yet offered to motorcyclists is also shown, and is in reality a combination of petrol cock, filter, and drain tap. This is a small cylindrical body which carries an inlet and outlet pipe. The inlet pipe screws into the tank and the outlet pipe is connected to the petrol pipe to the carburetter. The tap has three positions: on, off, and drain.

The Enots automatic lubricator is too well known to need description, but it may be mentioned that valve spring lifters, tyre pumps, filler caps, spare tyre carriers for sidecars, and many other diverse accessories emanate from the same house.



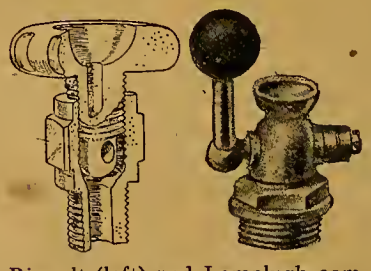
Ryley's lamp tubing clip.

Stand No. 164.
Brown Bros., Ltd., Great Eastern Street, London, E.C. 2.

AS is their usual custom, Messrs. Brown Bros. show a very comprehensive range of all types of motorcycle accessories. An interesting line is the Duco spring gaiter, which is now made for motorcycles embodying spring frames and spring forks of the leaf spring type. Only one model of the Vindec motorcycle is being shown; this is a Villiers engined two-stroke.

Stand No. 147.
Ryley, J. A., 73, Weaman Street, Birmingham.

AMONGST the various Ryley specialities shown at this stand, such as speedometers of various kinds, lighting sets, lamps, and horns of all sizes and descriptions, both bulb and mechanical, there is a very neat clip for attaching the rubber tubing from the generator to the lamps to the frame of the machine. This is a simple clip of spring steel in which is formed a loop to carry the rubber tubing. It is easily sprung over the frame member and securely holds the tubing.



Ripault (left) and Lamplugh compression taps.

Motor-Cycle Tyre's remarkable three years' record.

A Moseley motor-cycle tyre has done 23,400 miles in three years and is reported to be in excellent condition with lots of service still in it.

It is one of the rubber studded motor-cycle tyres, 26 x 2, and was fitted to a lightweight machine in December, 1915.

It was returned to us in January, 1919, with the information that during this period of 37 months it had been in continuous service and had covered an average distance of 150 miles weekly. When we received the tyre it was in excellent condition, there being a full one-eighth of an inch of rubber left on the tread.

Olympia in 1919.

THIS is an age of records! Our minds have been broadened by the custom of dealing in huge figures during the war, and this has had the natural effect of exerting its influence in peace-time programmes. The Car Show at Olympia broke all records, both in the matter of attendance and the volume of orders placed. The present Motor Cycle Show promises to outshine any previous exhibition of the kind. Its widespread interest was manifest on the opening days, and the future outlook is of the rosiest kind. The potential field of buyers in the motor cycle world is enormous, and must be greater than in any other sphere of automobilism, since the price factor must ultimately exercise a preponderating influence upon the buying public. A pleasing fact in this connection is that the British motor cycle industry remains supreme; indeed, its supremacy has never been seriously challenged in the same manner that imported cars threaten to challenge the lofty position which British-made motor vehicles enjoy. In saying this, we are fully cognisant of the excellent mounts, particularly powerful twin-cylinder machines, which find their way across the Atlantic, and we have also recognised, already, the great strides our French allies have made, since the war, in the production of high-class motor cycles. Comment is free and unchecked in this country, and to that fact we attribute, in large measure, the perfection to which the motor cycle has attained. 1920 design once again displays notable progress. With few revolutionary designs, the all-round improvement in well-tried models is not difficult to discern. Increased engine efficiency, due to a better understanding of the requirements in the design of an air-cooled engine, improved lubrication systems, superior materials—particularly for valves, which now need never break, thanks to aero-engine disclosures—studied accessibility, protected kick-starter mechanism, more adequate bearings for gear boxes, stronger transmission systems; these and more can be observed among the distinct improvements in modern motor cycles.

Standardisation is the motto of most progressive firms, only one or two models at the most replacing the range of patterns frequently favoured in the past. Luxury is a relative term, and it can be correctly applied to the modern economical motor cycle, for electric lighting outfits, detachable wheels, spring frames, and a jack for every wheel, are features commonly encountered. The sidecar coachwork, too, is specially attractive, and the now popular windscreen for the passenger, combined with a neat hood, give to the sidecar outfit a new delight which ladies are not slow to recognise.

Future of the Lightweight.

In particular we note with joy the increased attention being paid to lightweight motor cycles: a type of mount which sooner or later must prevail. Sidecar outfits there are in abundance, and commendable examples at that, replete with all desirable and essential equipment for touring. "No extras" is a feature of 1920 mounts. In juxtaposition, one may examine three-wheeled runabouts of varying types, and the ultimate battle between the two forms of three-wheeled motor cycles will be interesting to watch, the three-wheeler starting wtih the real advantage that both occupants are protected from the elements.

Many years ago, when dynamos were introduced for cars, we urged that it would be but a matter of time before dynamo lighting formed part of the standard equipment of a motor cycle. The 1919 Show exemplifies the coming of this new pleasurable era, and the passing of the acetylene lamp.

To all who can conveniently attend the Show, we promise that the time expended will be well spent and enjoyable, besides an education in the progress displayed by this the most economical section of the great and growing automobile movement.

An Index to the advertisements in this issue will be found on advertisement page 94.

ENCOURAGE THE LIGHTWEIGHT !

An Article in favour of Developing the Genuine Lightweight Motor Cycle. Open Frame and a Limit of 112 lb. recommended.

Lightweights have competed most creditably with larger machines in the leading competitions, but the boulder and rock-strewn tracks, combined with the high average speed, have resulted in weights growing up to nearly 200 lb.

A PLEASING feature of the present Olympia Show is the increased number of lightweight motor cycles to be observed on the different stands. The lightweight is a desirable type of mount to be encouraged and developed, though the term "lightweight" is elastic and often misapplied.

Few experienced motor cyclists doubt that the motor bicycle of the future for solo use will be a lightweight scaling, say, less than a hundredweight. We are not, of course, likely to get a perfect machine for the million next year or the year after, but its ultimate advent is a certainty. Are we progressing fast enough toward that ideal ? Let us look back a few years and endeavour to trace its progress.

Looking Backward.

Twenty years ago the original motor cycles, such as the Werner, the Minerva and the 1¼ h.p. Quadrant, were lightweights, but they died a natural death on account of lack of engine power, and failure to maintain the limited efficiency they originally possessed. As engines improved in quality, fourteen or fifteen years ago, further attention was given to the attempt to evolve the genuine lightweight, but even those attempts were premature, for engines in those days still lacked staying power, whilst change-speed gears (which help to cover up or camouflage the shortcomings of an engine) were uncommon. Again, designers went ahead with the practicable go-anywhere motor bicycle, and lightweights were neglected, despite the insistent demand for a light machine easy to handle and easy to manipulate and store. The Fairy and the Dougl were two excellent attempts to solve the problem, bu the Douglas grew in size and weight to the fine go anywhere machine it represents to-day.

The Advent of the Two-stroke Engine.

Years rolled by, and the two-stroke engine came int the limelight, due to Mr. Alfred Scott's long-continue experiments, and tiny two-stroke single-cylinder engine of a capacity no bigger than a teacup were evolved b Levis, Connaught, Triumph, Villiers, and others. I the two-stroke motor, engineers saw the solution o the successful light power unit for the 100 lb. machin that so many thousands yearn for. But road com petitions seem to have developed them on th wrong lines, for too much has been expected of thes lilliputian mounts when matched against more expensiv and powerful machines. They were, too, alway classified by engine capacity only, the all-importan factor of *weight* being ignored. The man in the stree is not seeking a machine which will climb mountainou

Encourage the Lightweight!—

tracks or a mount possessed of great speed and ability to traverse boulder-strewn hillsides. He seeks reliability, easy starting, and reasonable comfort and protection. Up to the present, the Auto-Cycle Union cannot be congratulated in ignoring the existence of this huge potential field of buyers. Its contests have seldom given special encouragement and prominence to the doings of the little chaps, and their performances have always been overshadowed by the bigger mounts, and the result has been a glut of double-purpose solo and sidecar machines, with no prominence for the low-priced lightweights, except what their intrinsic merits gained for them.

Special Lightweight Events Necessary.—

A little 2 h.p. O.K., in the Six Days Trials in Yorkshire, in 1914, demonstrated the capabilities of the type, but still no event was arranged to develop the breed of the true lightweight. Half the craze for unproved scooters last spring was, in the writer's judgment, due to the absence of trials and propaganda in favour of the true lightweight motor cycle. The choice of a motor cycle to-day commences with a machine of about 160 lb. (the weight of a 3½ h.p. machine of ten years ago), with the exception of the J.E.S. This state of affairs must not continue!

The Motor Cycle has led the way with the offer of a challenge cup for a genuine lightweight Tourist Trophy Race in the Isle of Man next year, recommending that actual *weight*, not engine capacity alone, define the machines to be admitted. But a race alone is not sufficient.

An Open Frame Advocated.

If the A.C.U. is to be regarded as the progressive body it claims to be for the development of the breed of motor cycles, lightweight events must form an outstanding feature of the 1920 competition programme. Lightweight motor cycles for solo use are safe in grease, easily lifted up steps or kerbstones (which facilitates storage), are cheap to buy and cheap to run, and on that account must outlive all other types. We want a lightweight which is midway between the best of the open frame scooters and the best modern lightweights, preferably with an open frame, so that a big coat may be worn in winter. Those actual and prospective motor cyclists who agree with the writer's remarks will notice with pleasure the increasing attention being paid to serviceable lightweight motor cycles, and the frequency with which they are encountered at Olympia. It is left to the A.C.U. and enterprising clubs to organise events in order to encourage the type, and demonstrate their road-worthiness. Commercial travellers in their thousands, and elderly riders who find pedalling too tiring, quite apart from the myriads of pleasure-seeking riders, await developments with more than ordinary interest.

Revolution Counters and Multi-gears.

How the Use of a Tachometer may Increase Efficiency.

IT often seems strange to me that revolution counters have never become popular among the motor cycling fraternity. They really provide a much more exact and reliable method of keeping a machine up to concert pitch and of getting the most out of a machine than a speedometer, and they would considerably enhance the pleasure of riding, at least to an enterprising and careful motor cyclist.

Imagine the pleasure of finding the number of revolutions at which the engine develops its maximum power, and, in the case of, say, a Zenith-Gradua or any other multi-geared machine, keeping the engine turning over at that number of revolutions, or as near as possible while climbing a long hill. It is a known fact that most speedometers are only accurate within limits. I think "Ixion" once stated that at speeds above 40 m.p.h. few speedometers are reliable; in this I agree with him entirely. Tachometers, on the other hand, have been made absolutely accurate and reliable.

In the case of a long-stroke single especially it is often found that on a long hill the engine settles down to a regular steady beat, much slower than would be expected. This is the stage when the maximum power is being developed. As examples for a comparison, I will choose the 5 h.p. Rudge-Multi sidecar outfit and the 6 h.p. A.J.S. three-speed combination. The Rudge has as its lowest gear about 7 to 1, as given by the variable pulleys; a high bottom gear compared to the 16 to 1 bottom gear given by the A.J.S. Yet I should say there is not much to choose between the two on hills. One engine is turning over just over twice as fast as the other, yet both may be developing the same power. The comparison between these two machines would be well worth trying if both were fitted with tachometers.

Supposing we know that an engine develops its maximum power at 2,000 r.p.m., it is a waste of fuel to run it at a higher rate. Under touring conditions the gears should be arranged to suit the normal revolutions of the engine. If we wish to climb a hill at twenty miles per hour and the hill demands maximum power, we must gear about 7 to 1. This would mean that the engine can only exert full power at 20 m.p.h. If we have infinitely variable gears we can make the engine exert full power at any road speed, which is really the ideal condition of things.

Under racing conditions, and particularly in the case of speed test on a hill, the revolutions of the engine ought to be considered. To reach the top of the hill in the shortest time, the maximum power must be given off. With the aid of a revolution counter and the knowledge of the critical number of revolutions, the gear best suited to the hill can be found more rapidly than by experimenting with gear ratios against the speedometer.

With fixed gear ratios perhaps one would not appreciate a tachometer, and that is probably the reason why it is not in general use. Of course, on every aeroplane it is a standard fitting, and now that motor cycles are tending to be influenced by aeroplane design perhaps we may yet see it as a standard accessory for motor cycles. An increase in the numbers of infinitely variable gears would no doubt encourage its use; and to judge by the patent lists and press rumours we may expect several varieties of friction gears for motor cycles.

ARGON.

Some Experiences of the Six Days Trials.

E. W. Merrall, with his Morgan, on the virgin rock road approaching the hill, Stay-a-Little.

A HASTY DECISION AND AN UNLUCKY ENDING.

READING the preliminary regulations of the Six Days Trials in *The Motor Cycle* fired our enthusiasm, and my friend and I decided to see if we could not win a gold medal. It was no easy task we had set ourselves, for my machine was an ancient Morgan Runabout, made in 1915, fitted with an 8 h.p. air-cooled J.A.P. engine; it was the *de luxe* model, and consequently very heavy. I had purchased the machine second-hand some three months previously, and most of the parts, especially the body-work, seemed to be on the point of dropping to pieces, for the machine had covered many thousands of miles before it came into my possession. My friends ridiculed the idea of entering a machine they jocularly dubbed the "Bath Tub" in such an event as the Six Days, and their most liberal estimates gave us a couple of days in the trial.

The Bath Tub earns its Title.

We did what we could to get the machine into shape, but not being experts and having few tools and no shop, we decided to go to the works for a final overhaul. On the Saturday before the trial we called for the machine at the works, and we were informed that they had had to replace one cylinder, as it was badly worn. An engine with one brand new 1919 cylinder, fitted with thin valves, but with the old piston inside it, and one old 1915 cylinder, with the original heavy valves, did not impress us, and we began to have misgivings as to the balance being upset. However, a trial run up the Old Wyche at Malvern, which we climbed with ease, set all our fears at rest, and we started for Llandrindod Wells in pouring rain, with no hood nor screen, as we had removed these fittings at the works lest we should reduce our speed in the trials with extra wind resistance. The machine certainly earned its title of the "Bath Tub" on the way to Llandrindod, for everything was swimming in water before we got there.

Monday came at last, and at the appointed time we were sent off, thirty-fifth in the procession, feeling none too confident as to the result. The consistent driving test came upon us unexpectedly, but we managed to lose no marks, and on the fast section we completed the course at 18 m.p.h. on our bottom gear of eleven to one, so the engine was capable of a high rate of revs. The long ascent over the moors from Llangynidr later on was a severe test for an air-cooled engine, but we came up without a sign of overheating. After tea at Abergavenny came the lamp test, and a long easy run home. Everyone seemed to pass the lamp test easily enough, but I wonder how many could have repeated this test at the end of the week. I, for one, could not have done so without the aid of some soap or putty, for on the Wednesday the water chamber sprang a leak, and emptied its contents into my passenger's boots.

A Test of Frames.

Tuesday's run was a test of frames; the surface had been cut up by heavy timber traffic, deep ruts and corrugations crossing the road at all angles. We bumped, swayed, and bucketed over the awful track that once had been a road at twenty miles an hour, every moment expecting a frame breakage. With our three tracks, we could not pick a course, even had there been a course to pick, which there was not. Surely purchasers of 1920 makes that came through Tuesday's test should not be troubled with frame breakages in ordinary use.

Beaten by Bwlch-y-Groes.

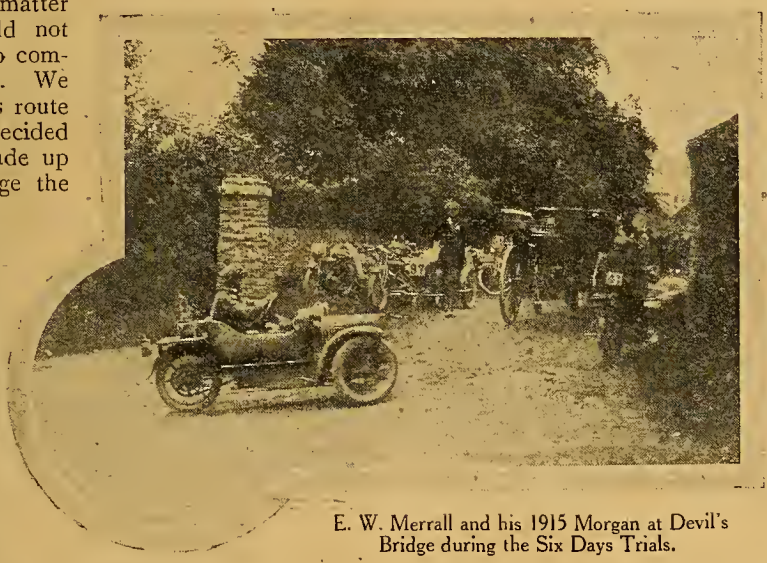
The Wednesday's route turned to be a test of hill-climbing; we climbed interminable hills till finally we reached the famous Bwlch-y-Groes Pass (1,790 feet). We went straight at the hill without any preliminaries such as cooling down and running out hot oil from the crank case, rounded the hairpin bend at the bottom on two wheels only, and roared up that first

me Experiences of the Six Days Trials.—

radient with ease, congratulating ourselves at having imbed the hill and wondering how far the lunch stop as. We changed up to top, rounded a bend in the ill, and our speculations about lunch froze on our ps, for there straight in front rose the second and orst instalment of the hill. I knew then that I had en over-confident; that fast drive to the foot of ie hill, rushing the first half, and the change up to p gear with its consequent wide throttle opening oved fatal to an air-cooled engine. A quick change wn to bottom again, and we went up the first bit; e engine was by now nearly red hot, there was not breath of wind on the hill, and the day was a velteringly hot one; we struggled on gamely till the igine petered out; my passenger dismounted, and I imbed the remainder of the hill alone. We reached e top in a chastened frame of mind, and resolved be more careful of Welsh hills in future.

A Change of Valves.

On Wednesday evening, my passenger and I con-lered the whole matter d decided we could not on with little or no com-ession in the engine. We udied the Thursday's route refully, and decided at time must be made up enable us to change the lves or grind them , so we started med with two spare lves and springs d a tin of grinding a s t e. Thursday orning gave us no portunity to make time anywhere, t, after lunch at the evil's Bridge, we d twenty-five miles splendid roads, t as far ahead of me as we dared, d stopped to change the valves outside Machynlleth. ortunately, I had a pair of Asbestol gloves on, but en then I burnt sundry other things, including my othes and my passengers' fingers in changing those hot lves. The new valve for the old cylinder left nearly eighth of an inch clearance between the valve stem d the tappet, and the tappets were the old 1915 fixed attern, so we decided not to use it, but to grind in the d valve. In this we were not very successful, though e certainly improved the compression; and it was ell we did so, for the biggest climb of the week omed in front of us, viz., Plynlimmon.



E. W. Merrall and his 1915 Morgan at Devil's Bridge during the Six Days Trials.

Atmospheric Conditions and Hill-climbing.

Fortunately for the competitors, there was a cold wind ith sleet blowing across the hill, amounting almost a gale near the top. Had the weather conditions n Plynlimmon been similar to those on Bwlch-y-Groes ie previous day, there would have been few clean scents of the hill, and we should certainly have been umbered amongst the failures. Later on in the after-oon, whilst climbing the little hill near Tylwch, the igh gear chain jumped off the sprocket through being too slack. It was most annoying to have a failure recorded against us on a hill we were romping up on top gear after climbing Plynlimmon. The subsequent repair to the chain cost us three minutes on the check outside Rhayader, a total loss of seven marks for the day; this, with four marks for failing on Bwlch-y-Groes, brought our total loss up to eleven for the week. This left us a balance of nine only if we were to secure the coveted award—none too wide a margin for the condition marks at the finish.

An Unlucky Day.

Friday's was the least picturesque run of the whole week: the district around Swansea seemed very uninteresting after the glorious scenery we had passed through on the other days. Friday morning and the first half of Friday afternoon were uneventful; we climbed all the hills, including Constitution Hill and Caio Hill, with ease, though the spectators on the first named gave us little enough room to pass a sidecar outfit crawling up on a very low bottom gear. Friday afternoon's course was rough and hilly, and most of the competitors lost time on this section, with the result that when a good piece of road did turn up it was a case of all out to make up the lost time. This proved our undoing. Near the village of Cilycwm, within thirty miles of the finish, and with a gold medal almost within our reach, we came to grief. Whilst travelling all out on a good piece of road, a large Welsh sheepdog suddenly darted into the roadway; the machine struck the poor animal with terrific force, though I did all in my power to avoid it. We swerved violently and collided with the bank, twisting the back wheel over at an angle of 45°; after that we struggled along, breaking and mending chains the whole way, and got up the consistent driving test hill at a speed of sixteen miles per hour on the fast section.

A Chapter of Accidents.

The petrol tank had sprung a leak owing to the collision with the dog, and whilst climbing a short hill outside Builth the engine "popped back" into the carburetter, and immediately the leaking petrol tank caught fire. We had a blaze, which my passenger extinguished with cap, gloves, coats, and anything he could lay his hands on.

Before the end of the day's run we broke yet another chain on that twisted back wheel, and finally landed home at Llandrindod Wells just over the hour late, and therefore counted as retired—gold, silver, bronze medals lost, back wheel twisted, and machine nearly lost through fire—all within thirty miles of the finish.

E. W. MERRALL.

Distinguo.

I BELIEVE it is a doctrine amongst Catholic schoolmen that any liquid may be used for purposes of baptism in an emergency, provided that liquid contains a major percentage of water. The story goes that a novice under examination in a seminary was asked whether baptism in soup was valid. His reply was, "Distinguo. If the soup be that supplied at the tutors' table the baptism might be valid; if the soup be that dealt out at our table, the baptism would unquestionably hold good." I should like to use his prefatory "Distinguo" to my critic, Mr. Henry Evans. In this column I necessarily deal with generalisations. Life is too short for me to cover 5,000 annually on a sample of every machine that is made. I write of machines as I find them. If they drip nuts, I generalise on this evil trait. It may well be that somebody makes a machine which never sheds a nut. If so, I have not ridden it. The last time I rode a Triumph in a trial, I shed four front brake shoes complete. (No, I was not robbed of my gold by the condition mark clause. I had previously shed similar parts in private riding, so I had a pocketful of spares.) I have not ridden a Sunbeam lately, so cannot join issue with Mr. Evans on that score. I will get hold of one, do a bit of road-burning, and report.

Three Types of Rider.

FROM a nut-shedding standpoint there are three types of owner. There is the man who treats his machine as an elderly spinster cherishes her one bit of Sèvres china—you must not breathe on it unless you have first taken a formamint. He counts the nuts every time he stops, and his bill for spares is small. The great majority of owners are less fiddley, but they are tolerably meek riders, and enjoy sufficient leisure to inspect the machine as often and as thoroughly as a regular company commander puts his men through it before the local general comes down. They do not drop very much on the road. Finally, there are madmen like myself. Nothing would please me better than to overhaul my mount nightly. But I simply have not time. I am the sort of fellow who burns the candle at both ends. I have two or three professions, a dozen hobbies, a score of public interests, and innumerable vices. My day is too short for a lot of wash-leather and spanner work. And I ride quite particularly "blue." It is cheaper for me to shed nuts than to make time to glance over the 'bus nightly or to pay somebody else to do it. Judged by this standard, I know no machine which is faultless. If it were difficult or impossible to prevent nuts from coming off, I would put the blame on myself, and hold my peace. But years of road experience have taught me that on several good machines there are only a few details which require periodic tightening. I kno those details, and *a fortiori* the makers know the better than I do, as their spare part orders reflect n experience raised to the *n*th power. It follows tha if these firms would apply one of the known and nume ous methods of securing the vulnerable details of the mounts, these machines would instantly become i vulnerable, even in the hands of such a 'bus-bust as myself.

And About Kick-starters.

THE same kindly critic chides me for anothe generalisation about kick-starters. Let it b granted that some kick-starters are better tha others: did I not impudently pat the P. and M. de signer on his broad back for that very reason? M main point was that the average is by no means goo enough. I select two illustrations from a bulgin memory. One is the mouth of my critic himself. H remarks, "the trouble is people do not drop the valv at the right moment." Exactly. (Or, rather, that i one of the troubles.) The average motorist is nc capable of getting the best out of an imperfect device Last week I watched the demonstrator of a famous ca company operate the electric starter of a brand ne chassis for some ten minutes by the clock withou getting a spit out of the engine. The week before friend of mine wrecked the battery of his new car b liberal use of his starter and head lamps during severa days with the dynamo permanently "off charge." M other illustration concerns a very famous rider indeed This summer I rode behind him for sixty miles on job which necessitated our stopping at very frequen intervals. He rode a very famous, very expensive out fit, which was so heavy that a kick-starter was essentia except when he started down a single figure gradient His machine had been most carefully and expertl tuned. Yet it was comparatively exceptional for hin to get it firing with one kick after a two-minute sto with a really warm engine. Awkward location of th kicker, insufficient leverage, poor tune, and a trick o dropping the valve too late prevent many motor cyclist from enjoying the potential blessings dormant in thei kick-starters. I fancy it is easier to devise a foolproo starter than to educate our community up to those w now have.

Why he did it.

SOME years ago I took delivery of a machine, and noticed that all its oil and petrol pipes, whicl were legion, included flexible insertions. asked the designer why he had incorporated these lengths of armoured rubber bound with wire. He le off some gas about frequent fractures due to vibra tion, which I denied hotly. Then he grinned, and said that the insertions were a manufacturing economy

Occasional Comments.—

—they saved a lot of expensive labour in fitting up. I never had sufficient curiosity to notice how such big firms as the Triumph and Douglas shape up their piping, but I am sure the large American factories use a jig. However, here is my point. I do not advise manufacturers to crib these insertions from aircraft practice. I have just spent a holiday in a rural fastness some ten miles from a garage, and all my insertions began to leak or even split, attaining decrepitude simultaneously. The local supply of tubing of any kind was scanty to a degree, and ranged from inflator connections, which were too small, to baby's bottle tubing, which was too weak, up to a formidable hosepipe which, I understand, had last been used for drenching a cow, whatever that may mean. I spent a very finicky half-day; and confess that I eventually made all tight by jointing the pipes with the tin portions of some cheap penholders, caulked with soap, and lagged with insulating tape. Incidentally, I discovered the real reason for the presence of these insertions on the machine. One of the oil pipes is—quite unpardonably—a three-branch or Y pipe, with very short arms. I will bet that the designer found these short stiff pipes snapped under vibration; and that if they did not snap, the task of registering three unions on one pipe was too much for his customers when they fell a-tinkering. So he solved that pipe difficulty by using rubber joints; and having by this time got fractured piping on the brain, he "dittoed" his petrol pipes for luck. I wish he had not.

The A.C.U. Hits Out.

EVER since the Llandrindod week, the trade and the A.C.U. have been engaged in a kind of billiard match. The trade broke the balls and scored a lot of points. Now the judges are at the table, and have piled up a big lead. I think the A.C.U. has emerged with the honours. It has conceded practically every point on which it was criticised, but, in return, it has shown a distinct gift for criticism. Indeed, some of the judges' strictures on modern design are so biting that it is almost a pity they have been published. Not because they are either exaggerated or untrue, but because for idealists the times are always out of joint, and the ideal machine for which the judges pine will not be produced for many a long day. Meantime the man in the street sees the report—it was condensed in many lay journals—and concludes that motor cycles are rotten. The case, rather, is that a good trials judge, exactly like a good technical journalist, should resemble an enthusiastic designer. All three men should cherish such high ideals that they are difficult to satisfy. On the other hand, the Six Days have their advertising side, and it is a blunder to utilise them for crabbing the machines which they are meant to foster, particularly when an average machine will do all that an average user can reasonably ask of it.

A Tale with a Moral.

THE other day I saw a distant push cyclist fall off his machine. As I approached at a rapid walk, he remounted, and fell off again. When I drew level with him, he repeated the performance. I saw at a glance that his pedalling chain had come off. Yet he made three separate attempts to ride on before he realised that his transmission had gone, and even then he had to examine the machine carefully before he realised what had happened. Now this individual was a member of the Metropolitan Police Force. Policemen are far above the average of the male population in intelligence. Men on the average are more intelligent than women in things mechanical. It follows that a motor cycle manufacturer builds machines for customers who are mostly fools. I think if I were a designer, I would get Gordon Crosby to make a sketch of the above incident, and I would hang it up in my drawing office.

THE PRINCE OF WALES'S VISIT TO MONTREAL.

The advance police guard in the procession from the station was mounted on sidecar outfits. In the U.S.A., too, the police, in their various spheres of operation, have long realised the value of the motor cycle.

CURRENT CHAT

Times to Light Lamps.

	Greenwich Time.
Nov. 27th	4.26 p.m.
,, 29th	4.24 ,,
Dec. 1st	4.23 ,,
,, 3rd	4.23 ,,

A New Record.

Once again *The Motor Cycle* establishes a new world's record in the circulation of motoring journals. The printing order for this Olympia Show Report Number exceeded 130,000 copies.

Accident to Col. Jarrott.

We regret that Lt.-Col. Charles Jarrott, C.B.E., President of the Motor Cycling Club, has suffered an injury to his foot, which has necessitated an operation. It is hoped that he will be sufficiently well recovered to attend the M.C.C. dinner on the 6th prox.

The Recognised Medium.

There is still great activity in the second-hand motor cycle market. 1,482 miscellaneous advertisements were published in the last issue of *The Motor Cycle*—more than three times the total appearing in any other motor cycling journal.

I.A.E. at Olympia.

Arrangements have been made for a special meeting of the Institution of Automobile Engineers for the discussion of the judges' report on the 1919 A.C.U. Six Days Trials.

The meeting will be held in the top room of the Princes' Suite at Olympia this (Thursday) afternoon, the 27th inst., at 2.30 p.m.

Summary of Lighting Regulations.

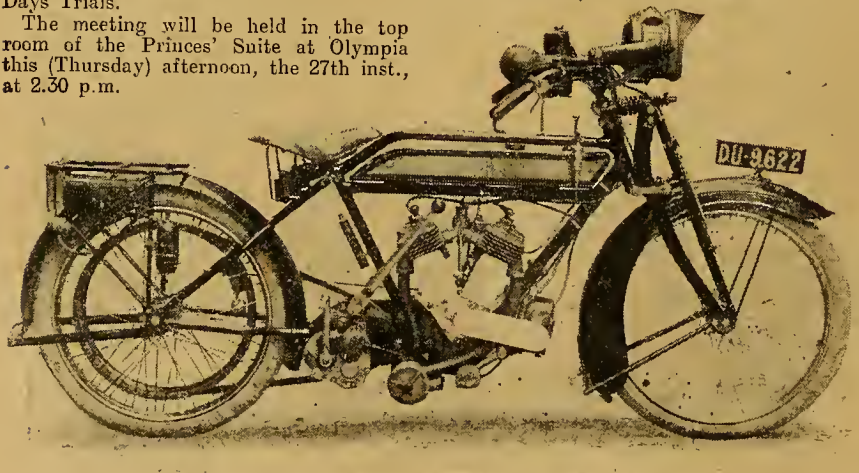
In the case of a motor cycle ridden solo, the following arrangement of lamps must be adhered to. *(a)* Lamp at front showing white light in direction which the machine is travelling. *(b)* Lamp at rear showing red light in the reverse direction. With a sidecar attached, two front lamps and one rear lamp must be used.

Contents of the Next Issue.

A continuation of the description of the Olympia Show exhibits will be published next week, when sidecar attachments and accessories will receive the same exhaustive treatment that the motor cycles and runabouts receive in this issue. Furthermore, critical articles upon the exhibits, by well known contributors to *The Motor Cycle*, will form a leading feature.

An Obstructive Cattle Drover.

At Petworth Police Court recently, the Automobile Association successfully prosecuted a cattle drover, under the Highway Act, 1835, for unlawfully preventing the free passage of the highway. The evidence showed that a motorist came upon a number of cows in the charge of the defendant, who refused to drive the animals to one side of the road and allow the car to proceed. He also stated that when driving cows he never gave way for cars to pass, and this statement was subsequently repeated to a police sergeant. The Bench fined the offender £1.



EX-POLICEMAN BUILDS AN ATTRACTIVE MOTOR CYCLE.

The photograph depicts a machine assembled by Mr. Challis E. Hircock, who has left the Coventry Police Force to open a garage in the City of Three Spires. The engine is a 5 h.p. J.A.P., and the equipment includes Sturmey-Archer gear, Brampton forks, Amac carburetter, and flexible exhaust pipes.

Special Features.

SHOW REPORT.
A PLEA FOR THE LIGHTWEIGHT
THE TREND OF DESIGN.

Metropolitan Police Activity.

We hear that the Metropolitan Poli are particularly active in seeing th motor cyclists are conforming to the ligh ing regulations. Particulars are beir taken with regard to the carrying of re lights and to the illumination of numb plates.

Life Membership of the A.A.

In response to a suggestion received b the Automobile Association, it has bee decided in all cases where a life membe has been "killed in action," to transfe such membership to the next-of-kin whe desired. Those interested are invited t communicate with the Secretary, a Fanum House, Whitcomb Street, Londor W.C.2.

Prominent Engineer Honoured.

Motor cyclists, especially those inte ested in Harley-Davidsons, will ur doubtedly join us in congratulating Mr Duncan Watson, managing director o the British interests of the famous Amer can firm, on his election to the Mayoralt of Marylebone.

Mr. Watson also, it will be remem bered, was recently elected a member o the Harley-Davidson Board of Director in America.

Manufacturing Facilities Wanted.

There are many new firms entering or about to enter, the motor cycle trade A glance at the Olympia Motor Cycl Show will show that some of them hav their programmes cut and dried, an their models well on the way toward production. At the same time our corre spondence shows that some firms, wh have recently decided to take up th manufacture of motor cycles, are hesitat ing as to which type of machine to adopt Such concerns will be interested to hea that we know of two recently demobilise officers who have almost completed th designs for a new motor cycle fitte with their own engine. Both thes gentlemen have sixteen years' experienc of motor cycles and have five years wa experience as D.R's., and added to thi they are responsible for the design of well-known and increasingly popula motor cycle.

We shall be happy to bring anyon who is interested in motor cycle construc tion into touch with the designers t whom we refer.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters must be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

A COMPETITION RIDERS' UNION.

Sir,—I should be glad to hear from enthusiastic competition riders, with a view to forming some sort of union for the purpose of determining what clubs and trials should be supported. Under the present system, the actual rider has no say in the matter, and I for one am very fed up with the methods of some clubs in their competitions.

ALBERT MILNER.

THE LIMIT.

Sir,—I quite agree with "Ixion's" comments on charges for accessories in last week's issue of *The Motor Cycle*.

The *6in.* King Dick pattern spanner is sold wholesale at 4s., and the retail price is 6s. Copper petrol tubing can be bought at 6d. per foot wholesale, and should retail at 1s. to 1s. 3d. easily.

I think it is about time some of the numerous trade organisations took up the matter of profiteering in the trade, and let the old price-cutting propaganda die out.

REG. SAMSON.

THE PARIS-NICE TRIAL.

Sir,—May I be permitted to draw the attention of both riders and manufacturers to the forthcoming Paris-Nice Trial, to be held in the early spring of next year.

This trial is likely to be very well supported, and will lead to a great amount of publicity apart from its own value. I feel that it is most important for us to realise in this country how large are the markets covered by a Continental trial of this kind, and I have been asked by one of the principal promoters to bring it to your readers' attention.

A. M. LOW, A.C.G.I., ETC.

AUTOMATIC CARBURETTERS.

Sir,—*Re* "Ixion's" first comment in your issue of November 13th, my experience in this direction may perhaps be of interest.

When cold my 'bus—a Coulson B (Capac carburetter)—absolutely refuses to fire unless the throttle is quite shut. When that is done, it starts quite easily without injection or flooding, but open the throttle only a little and one may push miles without success. Yet I can assure you that the carburetter is in perfect adjustment. I put it down to the fact that it is automatic, and that when really cold, unless the throttle is quite shut, the mixture is too weak. Shut the throttle, and the by-pass is able to supply sufficient juice to combine with the very small amount of air passing the butterfly throttle to produce a combustible charge.

As soon as the engine has fired a few times, and lost its first chill, the carburetter is perfect.

E. O. GURNEY.

VARIABLE GEARS AND BELT WEAR.

Sir,—I was glad to see the letter of "Rudge-Multi" in *The Motor Cycle*, and I too would like to help to dispel the hoary old superstition that multi gears are hard on belts. Properly used they are as hard wearing as any other system, and they are a perfect delight to drive. I have done over 6,000 miles on a Rudge-Multi in the last three years over some of the worst roads in Donegal, and I have yet to break my first belt. I must also say that the system is peculiarly easy on bearings and tyres. Usual disclaimer.

Co. Donegal. RUDGE-MULTI NO. 2.

Sir,—I read with interest "Rudge-Multi's" letter on the subject of belt wear with variable gears some little time ago. To my mind, the multi gear suffers from two disabilities: (1) belt wear; (2) belt slip.

As far as the former is concerned, I only got 1,500 miles out of my belt, and the next owner found the same, yet we both conscientiously tried to carry out the makers' instructions. When I meet a multi owner now I always enquire as to what belt mileage he obtains, and the great majority confirm my own experience, which convinces me that the average driver does not get normal belt mileage with this gear, while having to nurse the belt detracts from the pleasure of driving.

Now as to belt slip, this, I consider, is the more serious fly in the multi ointment. The pulley is smallest when belt grip is most required, *e.g.*, when *(a)* climbing a hill on low gear; *(b)* proceeding at a crawl owing to ruts and slippery surface. If the lowest gear position was still equal to a 6in. pulley, then the gear would be ideal.

I did a good deal of riding in hilly country and wintry weather, with lots of rain, slush, and snow, and it was the result of this experience which decided me finally to dispose of the machine.

In spite of these two disabilities, I should be the last to deny that the multi gear has a considerable charm, as witness the number of such machines on the road, whilst I myself, on a fine, sunny day with good roads, have felt it to be "a thing of beauty and a joy," but our British weather is unfortunately not always so.

J. D. MACDOWELL.

CARBURETTER BOOKLETS.

Sir,—We notice in *The Motor Cycle* of November 13th that Mr. E. R. Foyster says that he wrote to the makers of his carburetter for a descriptive booklet, in accordance with the invitation of their advertisement in *The Motor Cycle*, and has heard nothing from them.

As we invite our clients to apply for a descriptive booklet, we have gone to some considerable trouble to see if we have received a communication from the above named gentleman, but without result. We think, before statements of this kind are made, considering the conditions of the postal service at the present moment, it would be advisable for clients to follow up their request to see if their communication has been received in the first instance. We ourselves make a special point of dealing with all letters the same day they are received, and we should much appreciate your inserting a notice to this effect.

C. BINKS, LTD.

COMPRESSION RELEASE V. EXHAUST VALVE LIFTER.

Sir,—Referring to my old friend C. S. Burney's letter, in your issue of November 6th, he and your readers may be interested to know that several of the earlier motor cycle engines were fitted with a compression release and no exhaust valve lifter. At least one of the Minerva types was so fitted. The release took the form of a ball held against a coned seat by means of a spring with a Bowden wire operated bell crank and rod to force the ball off its seat against compression.

During 1904 I had a Forward motor cycle fitted with a 2¼ h.p. Cyclone engine, and, due to the nature of the gear operating the valves, an exhaust valve lifter was not convenient. I therefore fitted a large compression tap in the centre of the cylinder head with a lever and rod on the top tube to operate it.

I was present, with this so fitted, at the Auto Cycle Club's 100 miles passenger trial, starting from Hatfield on November 5th, 1904, when Julian Orde was the starter, and the event was won by Tom Sopwith (then about sixteen years of age) in a very masterly manner on a 6 h.p. water-cooled Pearson tricar.

HAROLD KARSLAKE.

PATENTS.

Sir,—I should like to draw your attention to a misstatement which occurs in the letter of your correspondent, Mr. P. Banham (October 30th), relating to methods of valve operation.

He says: "In the Beardmore . . . the rods are used only for opening the valves . . . which are closed in the usual manner, *i.e.*, by *spiral* springs."

In the Beardmore, however, the valves are closed by leaf springs, which, from my own experience in France with these engines, are much more satisfactory, and keep their strength much longer. In fact, I know of one engine in particular which did over 250 hours on one set of springs.

C. FURLONGER.

SILENCE.

Sir,—On reading the judges' report of the A.C.U. Trials, I was astonished to see that equal marks had been deducted from the Scott on the score of silence as from Triumphs, Ariels, and Nortons.

Surely Dr. Low's instrument is affected differently from the human ear.

I have ridden both the Scott and two of the singles above, and can easily give an approximation of their respective silence by the ability or otherwise of sustaining conversation with the passenger. The detonation of a single affects the human ear considerably more than the higher pitched hum of the Scott, even though the total noise may be about the same.

J. W. ROWLAND.

KICK STARTERS.

Sir,—In the issue for October 23rd there is an "Occasional Comment" by your contributor "Ixion" that is likely to give intending motor cyclists a totally wrong impression regarding modern kick-starter fittings. Apparently, it is his idea that there is not one really efficient one on the market. Personally, I have had two 1919 combinations this season, the first one a 4 h.p., on which machine the design and method of operation of the kick-starter left nothing to be desired, but, owing to the material employed, the teeth on the kick-starter sprocket wore very badly indeed, so much so that I disposed of the machine and obtained a new 3½ h.p. Rover combination. This outfit I have only driven for about 3,000 miles as yet, but the kick-starter, in common with the clutch and primary chain drive (three items which accounted for about 90% of my troubles on other well-known makes), has, up to now, given me no trouble whatever, and seems as near perfection as anything we can get in this imperfect world.

I may add that I have no connection with the Rover Co. other than as a very satisfied user of their products, but, being a manufacturer, although not in the motor line, I know what other people are up against in trying to give deliveries.

L.W.230.

Putney.

HONOUR TO WHOM HONOUR!

Sir,—Recently, through my carelessness in not keeping it properly adjusted, the whole hub, except the outer shell, of the back wheel of my 1914 Clyno went into "mash." How long it had been running like it before I discovered it, and how it managed to run at all, are mysteries to me.

I had to go across to London just recently, and broke my journey at Wolverhampton in order to get the wheel repaired.

Nothing could have been more courteous than the way in which I was received by Mr. Braine. He immediately started a man on the job, and then proceeded to enquire whether it was the firm's fault that the thing had gone wrong, as, if so, he would put it right free of cost. I have a shred of conscience left, so placed the blame in the proper quarter.

While the job was in hand he introduced me to Mr. Cocks, who, finding that I had very little time to catch the train, placed an experimental model sidecar outfit at my disposal to get to the station.

Usual disclaimer: though I must admit I have a big interest in the Clyno Co.—the interest any man takes in a firm that treats him decently.

H.J.S.

Dublin.

Sir,—A short time ago I bought a motor cycle from a friend. He informed me that the cylinder of the machine was cracked between the valve cap seatings and that the cylinder had been sent to Inverness to be welded. The firm there had retained it for *nine months*, and, after some correspondence, returned it to me *unrepaired* (stating that it was unrepairable). I at once sent it to Mr. Herbert Heap, 105, Bissell Street, Birmingham, who forwarded me *pro forma* invoice *three days* afterwards, and *within a week* I received the cylinder beautifully welded and rethreaded.

Such prompt and businesslike methods deserve commendation, especially when the great distance from here (Rossshire) to Birmingham is considered.

Usual disclaimer.

H. G. MACKENZIE.

DOUBLE CLUTCHING.

Sir,—I have never seen in your paper any reference to the process of "double-clutching" as applied to motor cycles, and it has occurred to me that if this method of gear changing were adopted more extensively, gears would benefit. Of course, I learnt it on a car, and have only tried it on a bicycle lately (2½ h.p. two-speed Imperial-Jap).

The application of this system to a clutchless bicycle makes the title seem rather inappropriate, but the method acts beautifully by using the neutral gear position instead of the clutch, and is easily acquired with a little practice.

The process is (changing down only, of course):

(1.) With the controls set to a small throttle opening, lift the exhaust lever; (2) change to neutral; (3) drop the exhaust lever, then accelerating the engine to the speed it ought to go at when in low gear (this only for half a second); (4) lift the exhaust and change from neutral to low gear. The dogs engage without a sound, and the exhaust lever is then dropped in the usual manner.

Apropos "Ixion's" recent remarks on Army haversacks, I have found them invaluable, and have discarded tool bags, even the armoured (?) type, in their favour.

B. Kershaw, on a 2¾ h.p. Blackburne-engined Verus, checking in at the conclusion of the event.

FROM

North to South in November.

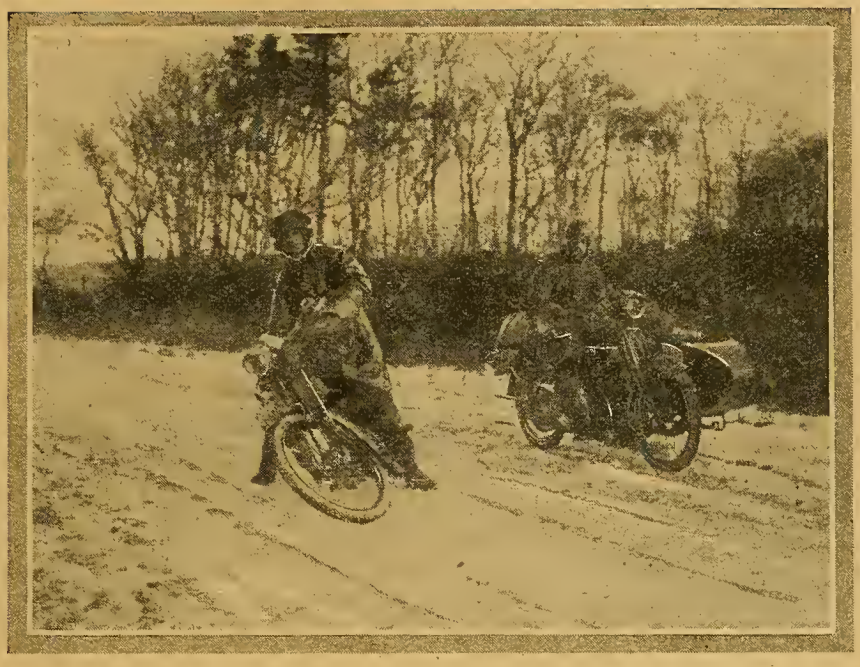
AN ENDURANCE TEST FOR MAN AND MACHINE.

750 Miles over Ice, Snow, and Mud on a New Single-geared Lightweight.

WHEREVER a wheeled vehicle can make progress the modern motor cycle is expected to go, and past trials and tests have proved that they are capable of such achievements. With three speeds, a powerful engine in relation to its weight, and a third wheel to prevent the possibilities of skids, a thousand miles run even in winter is within the scope of almost every owner of such a machine, but how many riders of a lightweight, single-geared and belt-driven, would care to undertake a winter ride from John-o'-Groat's to Land's End? The man who could accomplish such a run must be a very capable rider and a plucky one withal. There are many such men sufficiently enthusiastic to start on a ride of this character, but there are but few who could bring it to a successful conclusion.

But such a demonstration of endurance was carried to a successful conclusion last week, Messrs. Humphries and Dawes organising a John-o'-Groat's to Land's End run under A.C.U. observation. Capt. P. Pike was the chosen rider, the machine being a 2¾ h.p. O.K. with Union two-stroke engine.

Owners of machines costing from £100 to £150 should ask themselves whether they would care to undertake such a ride on their fully equipped mounts in the depth of winter, and then bring their mind to realise that Pike's machine costs but thirty-eight guineas. One may expect big things from a machine embodying everything designed to make riding easier, more certain and safe, but from a popular priced lightweight one naturally expects a more limited scope, and perhaps a little skimping in quality. But Pike has demonstrated that a low-priced machine is not necessarily shoddy, and the makers of the new O.K. have proved that good quality is possible at a low price by factory organisation permitting massed production.



For over 200 miles in Scotland, snow and ice covered roads were encountered.

Capt. Pike, with Mr. C. J. Cuffe, the A.C.U. observer, and Mr. S. Kempson Jones, the organiser of the test, journeyed to Wick, intending to start from John-o'-Groat's, but heavy snowstorms of a character responsible for long delays in the delivery of mails by rail and rendering the roads impassable necessitated a new starting point. The three "madmen," as they were harshly termed in the North of Scotland, made exhaustive enquiries regarding the state of roads south of Wick, but from everywhere north of Inverness reports were received

Through miles of traffic, fog and rain soaked roads, the intrepid rider of the O.K. was followed by the A.C.U. observer.

From North to South in November.—that road traffic was impossible, so the A.C.U. official refused to permit Pike to attempt the journey unless Inverness was made the starting point. Consequently the trial became a winter run from the Highland capital to the most westerly point of England, and a very rough journey it proved to be.

For the first 200 miles snow-bound roads were encountered, and in places ice made going exceedingly difficult, which resulted in several spills. For many miles the schedule speed of 20 m.p.h. was impossible.

The following extracts from telegrams despatched *en route* will convey some idea of the conditions Pike had to face :

First telegram, from Banff, reads :

"Roads snow, ice and water made progress slow—three hours behind shedule—travelling fifty miles east of route. Original route too dangerous, and A.C.U. would not proceed. Impossible to do any riding after dark; water in magneto which has now frozen solid, otherwise all O.K."

From Aberdeen :

"46 miles solid ice roads, change contact breaker owing to yesterday's flush, then rapid freezing, everything going O.K. Hope to reach Perth; polar bear wanted to complete arctic conditions."

From Perth :

"Welcome change in weather; wind, rain, sleet, and mud very bad; proceeding Dundee."

The rider recovering his machine after a skid on the ice bound road surface between Banff and Aberdeen

From Edinburgh :

"Reached Edinburgh ten o'clock after thirty miles blinding rainstorm."

From Newcastle :

"Roads very bad, much snow on Carter Bar, Berwick; though shows every sign of thawing at present."

After a further 250 miles in blinding sleet, the party arrived at Birmingham at 2 a.m., where they much appreciated the arrangements made for them at the Midland Hotel.

The following morning a restart was made in drizzling rain on the final stages to Exeter and Land's End. Pike was accorded a hearty send-off by Midland two-stroke enthusiasts who had turned out to see him off; in fact, in most towns where a short stop was made, readers of *The Motor Cycle* recognised him, and tendered good wishes for a successful run.

Captain P. Pike, 2¾ h.p. O.K.-Union, photographed on his departure from Birmingham. He was given a send off by local enthusiasts.

At the Show, Lady Motor Cyclists will be interested in—

The open frame Ixion.

The Sun-Vitesse open framed mount.

The Cedos lady's or gentleman's mount.

The oriental model Skootamota.

The various Lilliputian engined scooters.

The mirror in the dash of one of the Sandum sidecars.

The Bat limousine coupé sidecar for passengers of slender build.

The Mills-Fulford luxury sidecars, with tool compartments **not** under the seat!

Although it was noon before the party left the Midland metropolis, they reached Exeter (a distance of 160 miles or more) that night. Pike had the advantage of knowing the roads well, and, despite their muddy state, the original schedule speed of 20 m.p.h. was well maintained.

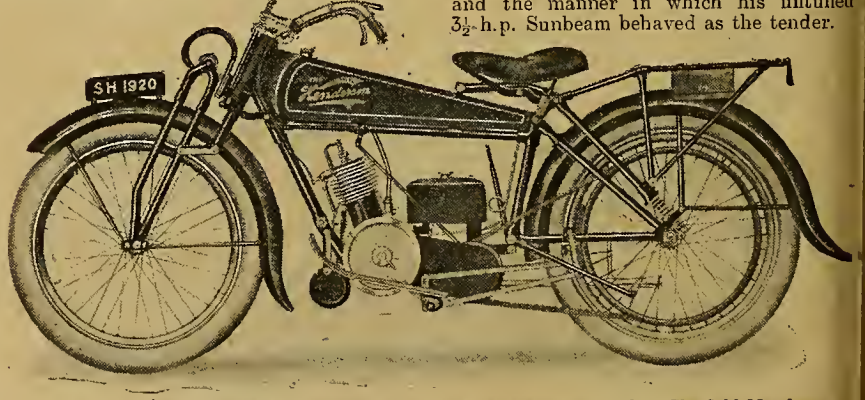
Early next morning *The Motor Cycle* received a telegram from the Devonshire county capital, from which the following is an extract :

"Going well now, leaving on last day's run of the trial to Land's End."

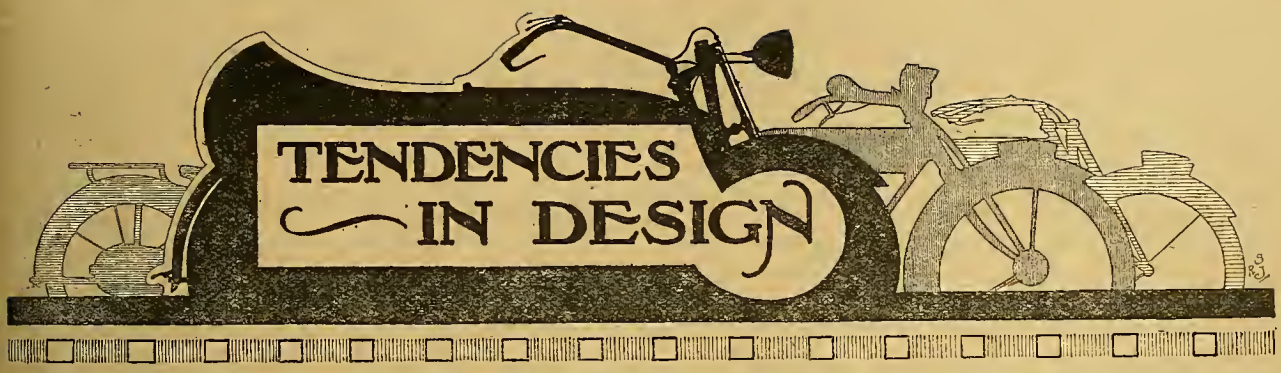
Then came the final message that the O.K.-Union reached Land's End on Saturday evening last. For the last four hours of the long journey thick mist and heavy roads were encountered—a fitting conclusion to a week during which not a mile of dry road was covered. All hills were climbed with power in reserve.

Pike's machine was immediately taken to Olympia, where it forms an attractive exhibit on the stand of Messrs. Humphries and Dawes.

We congratulate Capt. Pike upon the successful issue of his undertaking, and also Messrs. Humphries and Dawes upon the performance of their new machine, which makes its *début* to the public in such a praiseworthy manner. This record of a trying test would not be complete without some reference to the sportsmanship of the A.C.U. observer, Mr. Cuffe, and the manner in which his untuned 3½ h.p. Sunbeam behaved as the tender.



Designed by one who objects to the shackles of the convention, the 2¼ h.p. Sheffield-Henderson bristles with new features.



A Commentary on the 1920 Olympia Show from an Engineering Standpoint.

Predominant Features of 1920 Design: Flat Twin Engines—Spring Frames—Mechanical Lubrication—Countershaft Gears—All-chain Drive.

A ROUGH survey of the Olympia Motor Cycle Show is apt to convey the fallacious impression of a general rehashing of pre-war designs. Closer inspection will reveal the importance of various tendencies observable. One must remember that the last Olympia Motor Cycle Show took place in 1913, and it is with that event that the present exhibition should be compared, since the number of motor cycles produced for public use since that date is negligible. Motor cyclists, however, are notoriously keen on their hobby, and, in spite of the war, most of them have kept in touch with the doings of the motor cycle world. In consequence, they are apt to look upon the few experimental models produced during the war as accepted types, and to be disappointed at the lack of change in the standardised types displayed.

Manufacturers as a whole are only just able to concentrate upon their peace-time programmes, and their efforts to improve have been fruitful, as a little study will show.

As might reasonably be expected, the greatest novelties are staged by new firms, who are not handicapped by the necessity of scrapping existing patterns and machinery, in resolving upon a new model. It is probably true that these firms will, for a time, lead the way in departures from accepted design. Much greater strides may be expected in the next twelve months.

ENGINES.

Flat Twins.—The most pronounced tendency in four-stroke engines is the adoption of the flat twin—a tribute to the Douglas. Such additions as the new A.B.C., Humber, Brough, Zenith, Coventry Victor, Harley-Davidson, Raleigh, and Wooler make an imposing list, and clearly show which way the wind blows.

Two-strokes.—Another most noticeable feature is the increased number of small two-strokes, a type of engine which has been considerably improved in detail since the Show in 1913. These engines offer a simple manufacturing proposition, and can be sold cheaply, added to which they give excellent service, especially to that ever-growing section of the public which desires a machine simple to handle, and with a minimum of complication. Generally speaking, there is a lack of originality in two-stroke design except for minor details, the most striking exceptions to this rule being the Cedos, Dunelt, Black Prince, Velocette, Union, and Scott. The last-mentioned must be considered original in more ways than one, though it has undergone but little alteration since the last Show. Two-strokes of the larger size are becoming more numerous, of which the Dunelt (500 c.c.), Alecto (350 c.c.), Paragon (350 c.c.), and Precision (350 c.c.) may be mentioned.

Outside Flywheels.—The increase in flat twins and two-strokes is partly responsible for the fact that the outside flywheel is at last coming into its own, though the smooth running of the Blackburne engine is responsible for much useful propaganda in this respect. It is also significant that several small four-stroke engines on exhibition have outside flywheels.

Overhead Valves.—Enthusiasts will be disappointed at the small number of British engines fitted with overhead valves, but one may expect developments in the next year or so. There is already a tendency amongst new firms to incorporate this feature in their designs, and the sceptics will gradually be converted. The difficulty of fitting an overhead valve engine in a low frame has been the cause of a few firms holding back. There is a prevalent idea that overhead valves and gear are unreliable, but the sooner this notion is dismissed the better for the advancement of motor cycles.

Lubrication.—Fortunately for riders, the vexed question of lubrication is receiving more attention, and several firms are now marketing models with mechanical oiling devices, while many more are experimenting in that direction. The Humber (4½ h.p.), Douglas (3½ h.p. and 4 h.p.), Velocette, Clyno, Rex, J.E.S., B.S.A., P. and M., and Precision are amongst the British converts to mechanical systems, moreover the F.N. and practically all American machines are so fitted.

Composite cylinder construction is unusual, and is, in fact, limited to two or three examples in the Show, though a good deal of experimental work is being done in this direction, and aluminium pistons are beginning to make headway.

Protected Valve Gear.—There is still plenty of room for improvement with regard to quiet valve gear, and in this connection it is curious that more firms have not given their minds to enclosing tappets and valve springs. This can be done without materially detracting from accessibility, and it has the additional

advantage of reducing wear on valve tappet guides.

The growing popularity of the sidecar has caused a rise in cylinder capacity as regards single-cylinder engines, though in the twin class there are but few new 1,000 c.c. engines. The Clyno is perhaps the most striking example of up-to-date design amongst the new large engines on view.

GEARS.

Tourist Trophy races and experience during the war account for the disappearance of the hub gear. A light two-speed countershaft gear is the most favoured for lightweight motor cycles. Countershaft gears in one form or another are almost universal, the exceptions being those firms who stand by the simple belt transmission, such as the Rudge, Zenith, and Wooler, and even the Zenith may be said to possess a countershaft. One of the simplest and most efficient types of countershaft gears—the expanding ring type—as exemplified by Enfield, Scott, and P. and M. machines, has gained some new adherents, notably the Dunelt and the Precision.

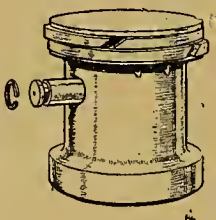
Three-speed countershaft gears may be considered to be standard for sidecar machines, but the majority of light solo mounts have two ratios only, the A.B.C. being an exception, with its four-speed box. Proprietary gears are more common than gear boxes made by the manufacturer of the motor cycle, and motor cycles as a whole give the impression of being assembled rather than designed. This criticism requires qualification, as the assembling of specialised parts is often desirable, provided that each part has reached a sufficiently advanced stage of development, and that the complete machine is well laid out.

Provision for Adjustment and Oiling.—Oil fillers for gear boxes are often too small, but more attention has been paid to the methods employed for moving the boxes to adjust the primary chain. The new Triumph micrometer adjustment is excellent, whilst the Cedos, Lea-Francis, and Matchless are also first-class in this respect. Some firms, notably the British Excelsior, fit simple micrometer adjustments to proprietary gear boxes.

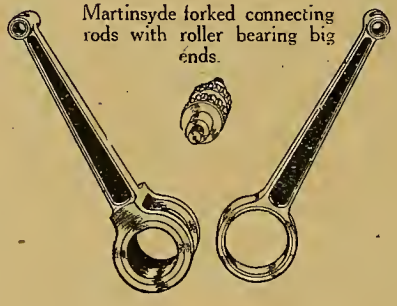
Epicyclic gearing is conspicuous by its absence, in spite of the fact that it is a very quiet form of gearing, and

INTERNAL FEATURES OF 1920 PATTERN ENGINES.

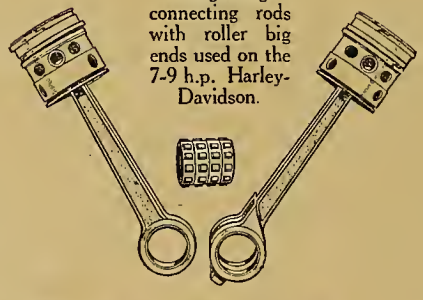
Heat insulator (sectioned) at top of valve springs on the 1920 3½ h.p. Sunbeam engine. Knife edges at points of contact with cylinder and valve guide prevent conduction of heat.



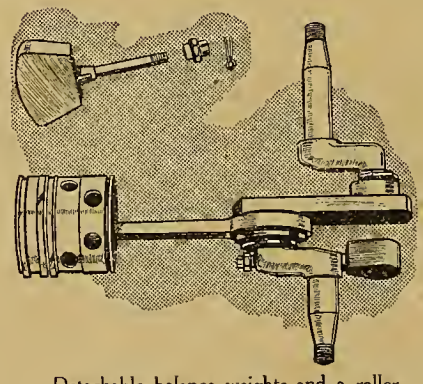
A deep waist is formed on the 6 h.p. Martinsyde piston. Note the gudgeon locking device



Martinsyde forked connecting rods with roller bearing big ends.



The single forged connecting rods with roller big ends used on the 7-9 h.p. Harley-Davidson.



Detachable balance weights and a roller bearing connecting rod are features of the Harley-Davidson flat twin engine.

provides a very smooth pick up; probably the difficulties of manufacture are responsible for its non-existence. Amongst the simplest forms of variable gear ratio, the Philipson pulley must not be forgotten.

TRANSMISSION.

We seem to be as far as ever from the weatherproof shaft drive of idealists, although this system of transmission is not entirely absent.

Variable pulley gears are in much the same position as in 1913. The firms who specialise in this form of transmission have retained their designs, and little change is discernible. Chain and belt drive is the usual form of transmission for the lighter machines; such exceptions as the Enfield and Velocette may be considered to prove the rule. This type of drive is still used on many of the larger machines, but all-chain drive has made considerable progress. In conjunction with a well-designed shock absorber, it forms an admirable transmission, especially for sidecar machines, and some of the shock absorbers now marketed are truly excellent.

Combined engine-gear units retain the position they held in 1913, although not necessarily by the same manufacturers. The big single Quadrant, Precision, and Paragon are among the new designs embodying this principle.

Little doubt exists that a totally enclosed chain running in an oil bath is the best form of primary drive, though there is still considerable divergence of opinion as to the desirability of totally enclosing the rear chain. To quote examples: The Triumph, Ariel, Indian, and others prefer an open chain protected at the top, while the Sunbeam, Lea-Francis, Raleigh, and Clyno, among others, believe in an entirely enclosed chain; whilst the Rover, after a year with an enclosed rear chain, now appears with a guard only. From the point of view of accessibility, the former scores, but rear chains should obviously last longer and need less attention when completely enclosed.

FRAME DESIGN.

The Motor Cycle has consistently urged the desirability of spring frames, and it is encouraging to note that this feature each year makes considerable headway. New spring frames are exhibited on the 3½ h.p. Douglas, the A.B.C., Matchless,

Raleigh, Indian, Royal Ruby, Precision, Paragon, Coulson, Wooler, and Clyno.

Many other firms are experimenting in this direction. The spring suspension of the type so well proved by the Bat and Edmund, in which the saddle and footboards are sprung, has also gained new support.

Spring saddle-pillars are found on the Ariel, A.J.S., B.S.A., Chater-Lea, and Rex; and the Barnes spring saddle, as fitted to the Zenith, creates a new departure, in that the springing is so excellent that some consider that it obviates the necessity of spring frames. Straight top tubes have gained a lot of ground, and amongst the many firms who have adopted this practice are the A.J.S., Clyno, Raleigh, Hobart, A.B.C., Allon, Excelsior, Chater-Lea, Dunelt, Coulson, Verus, Levis, Velocette, O.K., and Quadrant.

There is a noticeable tendency to use steel lugs instead of malleable castings; but beyond these points the A.B.C., Precision, and Black Prince form the most striking examples of original frame design. The Precision, in particular, is interesting in that, besides utilising the pressed steel tank as a frame member, the mudguards are specially heavy, and are used to triangulate the front and rear frames.

TYRES.

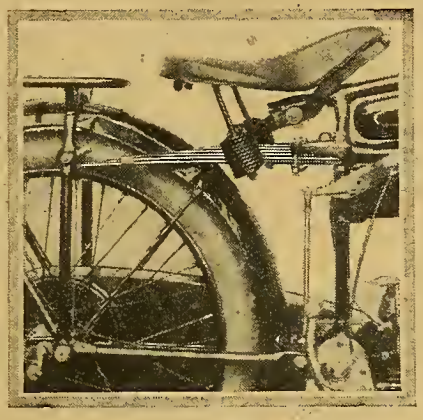
In almost every case, tyre sizes have increased: we record this with pleasure. The section which in 1913 was considered ample for a 3½ h.p. speed machine is now in almost standard use on 2½ h.p. lightweights. On passenger machines detachable and interchangeable wheels are becoming universal practice amongst the heavier machines, at any rate, and their diameters, too, have increased to 28in., whereas at the last Show this size of wheel was practically confined to American motor cycles.

MUDGUARDING.

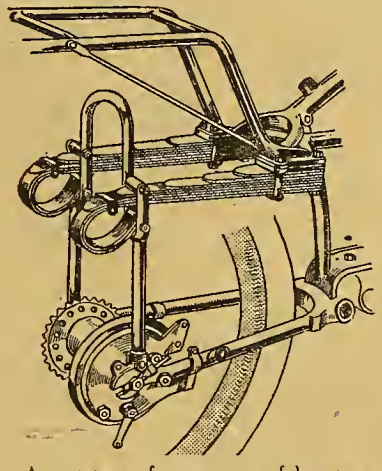
Mudguarding has received the attention due to it, large guards and better designs in valancing being obvious improvements on most new models, while the problems of accessibility have not been overlooked, although not entirely overcome, by many designers.

In finishing their machines, makers now show a decided tendency to reduce the number of plated parts, while tank decoration is more conservative, the black and gold finish being much in evidence.

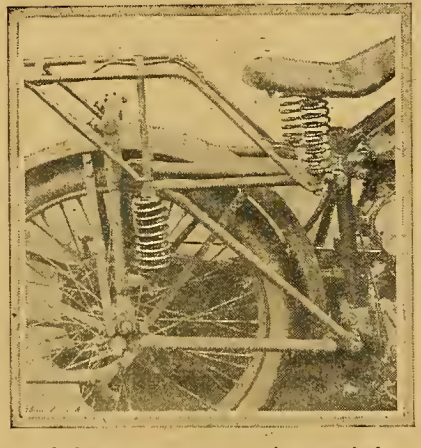
REAR SPRINGING SYSTEMS.



One of the few machines in which completely enclosed chains and a spring frame are combined is the 5-6 h.p. flat twin Raleigh.



A prototype of many successful systems of rear springing, the Indian cradle spring frame.



Coil springs are not often used for frame springing on heavy sidecar machines, although they are successfully employed on the Matchless.

SCOOTERS.

In the junior class of motor cycles, the scooter must not be overlooked. The several excellent examples of these miniature motor cycles attract their full share of attention, particularly those provided with a seat. As *The Motor Cycle* has often asked, why stand? Some of the most interesting engines in the Show are to be found among these lilliputian power units. The Whippet, for instance, with aluminium cylinder and overhead valves, is the only example of the steel lined cylinder with aluminium fins with which such progress was made during the war by aircraft engine experts.

CARBURETTERS.

Single-lever carburetters are shown on many makes of machines. This practice has been standard in America for years past, and has formed one of the great attractions of American motor cycles, and it is surprising that it is not, already, more common in this country. Two-lever carburetters are sure to be retained for some time by the speed enthusiast, but, without a doubt, the average rider will get as good or better results out of a single-lever instrument.

There are several new automatic carburetters designed specially for motor cycles, and as a proof of the satisfactory results obtained from them it is only necessary to note the names of the firms who are now standardising this type. Like most other mechanical devices, there are good and bad instruments, but, after several years' experience of automatic carburetters on motor cycles, it may safely be stated that good single-lever types are very good, and will be found to be a blessing which will be especially appreciated by novices and those who use their motor cycles for business purposes.

NEXT WEEK!

"THE MOTOR CYCLE" for December 4th will include a Review of the Sidecar Attachments and Useful Accessories at Olympia, besides other Special Articles commenting upon the Show Exhibits. It will be an enlarged issue.

Out on THURSDAY. 3D.

A REVIEW OF 1920 MODELS

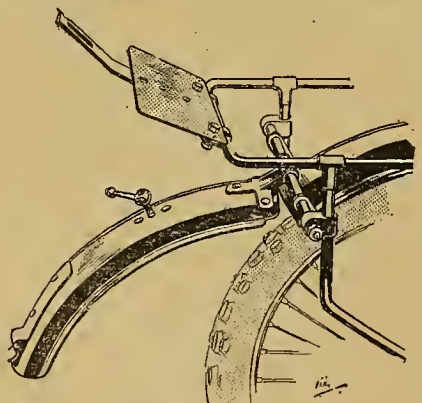
A STAND-TO-STAND DESCRIPTION OF THE MOTOR CYCLES, SCOOTERS, AND RUNABOUTS DISPLAYED AT THE MOTOR CYCLE SHOW (NOV. 24th-29th).

The reports have been prepared by the staff of "The Motor Cycle" after personal examination of the exhibits, and are arranged in three sections for the convenience of the reader.

ABINGDON, Nos. 34 and 140.

3½ h.p. single four-stroke MODEL: 85×88 mm. (499 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett magneto, chain driven; three-speed gear; chain-cum-belt drive; 26×2½in. tyres. Also single gear model.

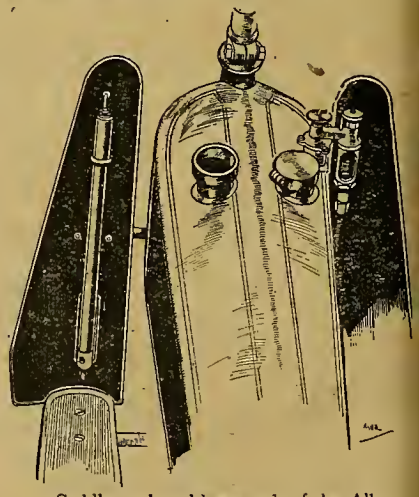
ABINGDON-ECCO, LTD., Tyseley, Birmingham.—Two types of single-cylinder motor bicycle are to be seen on this stand. The 3½ h.p. sporting T.T. model single gear belt drive, and the touring model equipped with three-speed gear, kick-starter, and chain-cum-belt transmission. Abingdon-Ecco, Ltd., are famous for their carefully made engines, of which the system of lubrication has been an outstanding feature for many years; in fact, their designer was one of the first motor cycle engineers to study the cutting of oilways in the bearings in an intelligent manner.



Hinged rea mudguard of the Abingdon King-Dick.

6-7 h.p. V twin four-stroke MODEL: 73×95 mm. (795 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett magneto, chain driven; three-speed sliding gear; chain drive; 28×3in. detachable wheels.

This is a medium price practical 6 h.p. sidecar outfit with chain-cum-belt drive,



Saddle tank and leg guards of the Allon two-stroke. Note the position of the inflator.

WHAT THE SHOW REVEALS.

ON other pages of this issue will be found an exhaustive review of the tendencies in design in 1920. For the benefit of those readers visiting Olympia with the object of studying the progress discernible in the new models displayed, a brief *resume* of the more notable features of the Show is appended:

(1) The large proportion of flat twin engines.
(2) A great increase in the number of machines fitted with two-stroke engines.
(3) The almost universal adoption of countershaft gears.
(4) The popularity of all-chain transmission.
(5) Improvements in lubrication systems.
(6) A desirable increase in tyre sizes.
(7) Improved mudguarding.
(8) The proportion of spring frames and saddle-pillars (in favour of which *The Motor Cycle* campaign will be recalled)
(9) Straight top tube frames.
(10) The remarkably complete equipment of sidecar combinations.
(11) More three-wheeled runabouts.
(12) The prevalence of dynamo lighting.

The Olympia Show.—

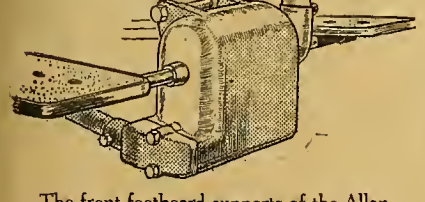
Transmission side of the 6-7 h.p. twin Abingdon power unit.

thoroughly well thought out, and is similar in its main details to the more elaborate chain-driven model which is an extremely handsome well-finished and solidly constructed sidecar outfit equipped with enclosed chain transmission, which is capable of going anywhere. The question of lubrication has been well studied, and to this machine the Benton and Stone new lubricator is fitted, with drip feed working by suction and incorporating a hand pump for emergencies. It is fitted with a mudguard in which a large section is detachable, allowing access to the major portion of the tyre. The lower portion of the mudguard is hinged and fastens against the back number-plate, which likewise swings back. This operation is effected by undoing one wing nut and only occupies a few seconds. This model is fitted with detachable wheels, and is well worth the attention of the sidecar enthusiast.

A.B.C., No. 23.

3 h.p. flat twin four-stroke MODEL: 69×54 mm. (398 c.c.); overhead valves; Claudel carburetter; C.A.V. gear-driven magneto; four speeds, sliding gear; chain drive; 26×2½in. Clincher tyres.

THE SOPWITH AVIATION CO., LTD., 65, South Molton Street, W.1.—The A.B.C.



The front footboard supports of the Allon pass through the silencer.

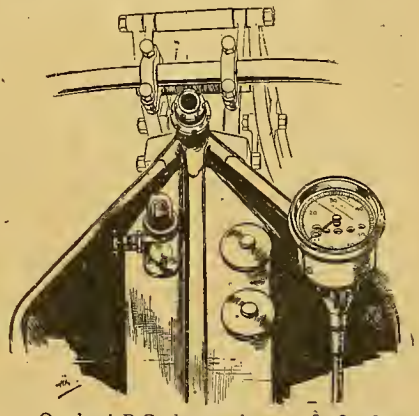
For Scooters see page 682.
For Runabouts see page 684.

exhibit consists of five models, of which one is attached to brackets on a built-up wall, to which it is fixed by the sidecar lugs. The background is of white plush, and electric lamps cast their light upon the backgrounnd, and the machine stands out in relief against it—a very excellent idea. There is also a complete engine in section, and several black pyramids on which are shown the various component parts of the machine. For the first time the general public will be able to see the production model A.B.C., which has now really been brought down to its final stage. There are still points about the finished model upon which we have not yet dwelt. Among these we may mention a needle valve type compression tap at the foot of each inlet pipe adjacent to its union, an excellent accumulator box, the top and sides of which are quickly detachable, and provided with rubber studs, keeping the accumulator firmly in position. The accumulator box is carried on the sprung portion of the machine, and this is an important point. The electrically equipped model has a celluloid



On the A.B.C. the speedometer is fitted in a convenient position on the tank. The large tank-filler caps will be observed.

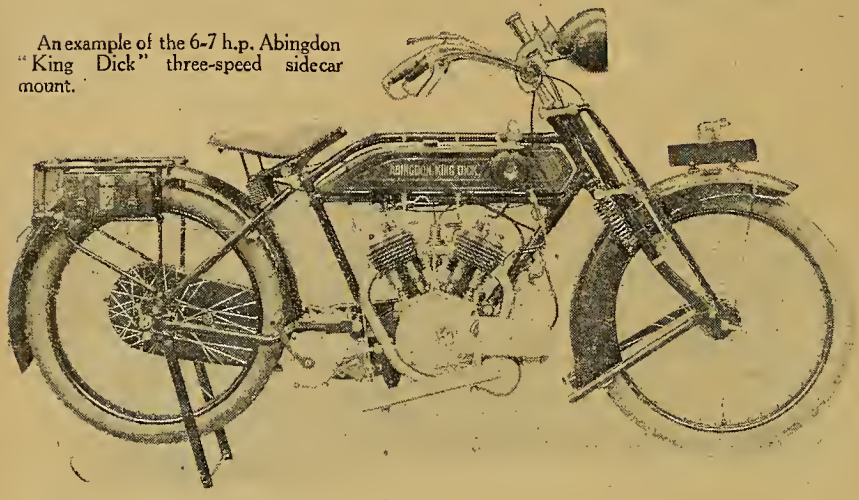
top fitted to the gear box, so that the interior mechanism may be clearly seen, but this is only for show purposes. Abaft the carburetter is the metal switch-box in which there is sufficient space for the carrying of bulbs and other spares, while underneath the engine is the tool-box containing two spanners for every nut on the machine. A kick-starter of novel design is also shown for the first time.

ARIEL, No. 59.

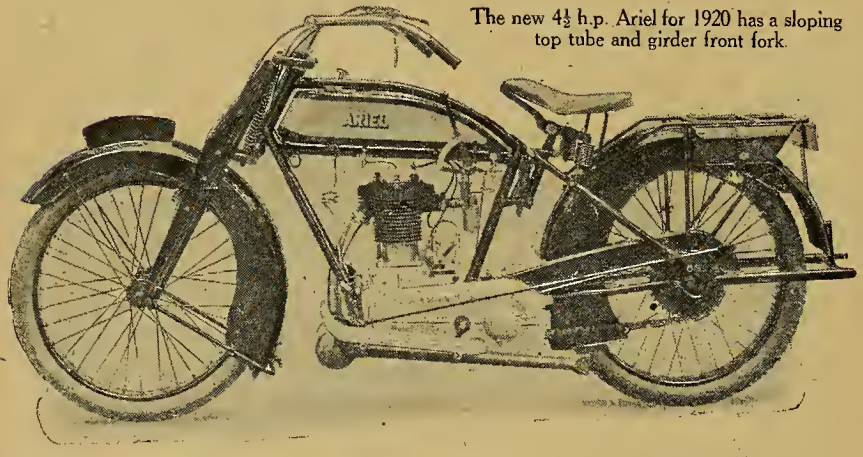
4½ h.p. single four-stroke MODEL: 86.4×100 mm. (585 c.c.); side-by-side valves (decompressor); B. and B. carburetter; E.I.C. chain-driven magneto; three-speed sliding gear; chain drive; 28×3in. tyres.

ARIEL WORKS, LTD., Bournbrook, Birmingham.—The success of the Ariel single-cylinder machine as a sidecar mount in the pre-war and post-war trials has induced Messrs. Ariel Works, Ltd., to introduce a new single-cylinder model with a larger engine. The engine follows the general lines of the 3½ h.p. model, but has a capacity of 586 c.c. instead of 500 c.c. As on the 3½ h.p.

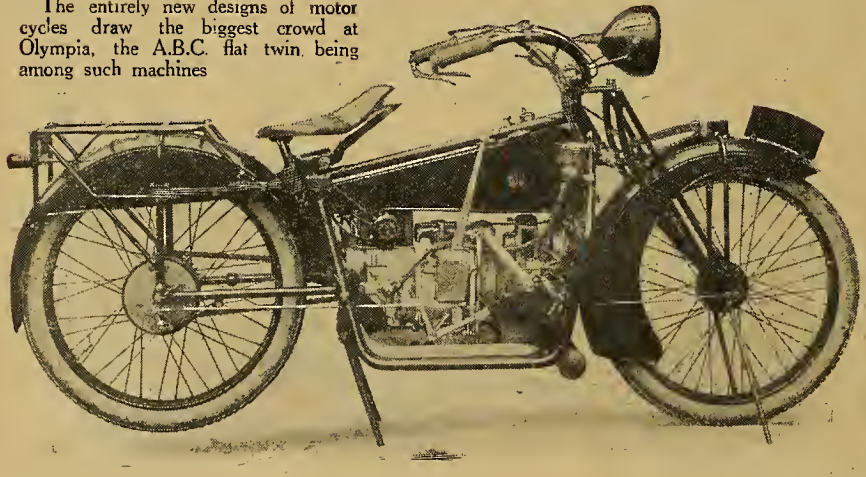
A Notable Trio of 1920 Models.



An example of the 6-7 h.p. Abingdon "King Dick" three-speed sidecar mount.

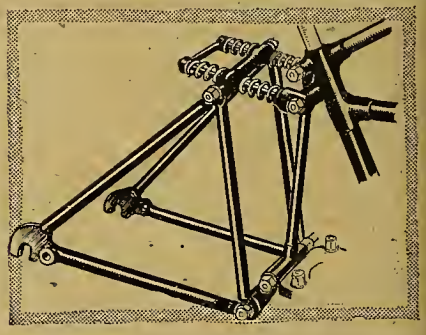


The new 4½ h.p. Ariel for 1920 has a sloping top tube and girder front fork.



The entirely new designs of motor cycles draw the biggest crowd at Olympia, the A.B.C. flat twin being among such machines

model, a decompressor is fitted, but for the first time the exhaust lifter lever is omitted. The gear box is the same that has been fitted to Aricls for the past few years, but here all resemblance to the later types disappears. The outstanding feature of the new models is the pressed steel front fork, which is of the parallel link type, and has two long coil springs, which are used in tension. The frame at first strikes one as being somewhat high from the ground, but the top tube has a pronounced curve, which commences almost at the head. The front part of the frame is of duplex construction, and is bolted directly to the front of the crank case. Another feature new to the Ariel products is the adoption of all-chain drive. The final chain is of the spring link type, and the hubs of all wheels have hollow spindles, and are lubricated through the outer nut of the spindle. The rear brake is of the internal expanding type, carried



An unusual type of rear suspension on the new Ariel.

inside the rear wheel sprocket. A feature which is more important now than it was before the war is the Ariel spring seat-pillar, which is fitted to all models; while the wide and detachable valanced guards also will be much appreciated.

3½ h.p. single four-stroke MODEL: 86.4×85 mm. (498 c.c.); side-by-side valves (decompressor); B. and B. carburetter; E.I.C. chain-driven magneto; single-speed; belt drive; 26×2½in. tyres.

This machine is identical in every way with the 1919 pattern, and is the one which has done so much to enhance the Ariel reputation as a single-cylinder sidecar mount. The engine is fitted with a decompressor, but on this model an exhaust lifter is also fitted, apparently only for the reason that deviation from the 1919 specification has not been made. The equipment of the machine includes Druid forks and chain-cum-belt transmission.

6-7 h.p. V twin four-stroke MODEL: 73×95 mm. (795 c.c.); side-by-side valves; Amac carburetter; E.I.C. magneto, chain driven; three-speed sliding gear; chain drive; Dunlop 28×3in. detachable wheels.

This model is in general outline similar to the 4½ h.p. type, but is fitted with a 6-7 h.p. long-stroke twin engine, and altogether forms an interesting addition to the range of big twins now available.

Stout Gent : "Excuse me, Sir, can you tell me the quickest way of getting to the Station ?"

Enthusiast : "Rather ! by far the quickest way to get there or anywhere else is to 'Rudge it !'"

In answering this advertisement it is desirable to mention "The Motor Cycle."

MARK 7.

MOTOR CYCLES BY

MASS PRODUCTION

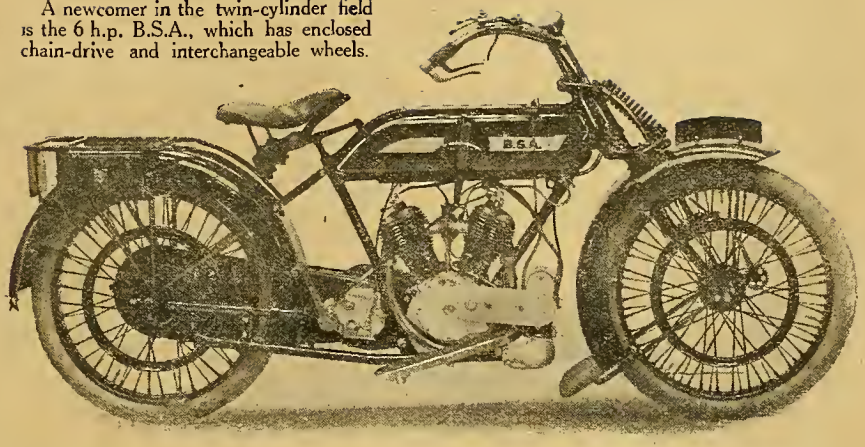
The Olympia Show.—

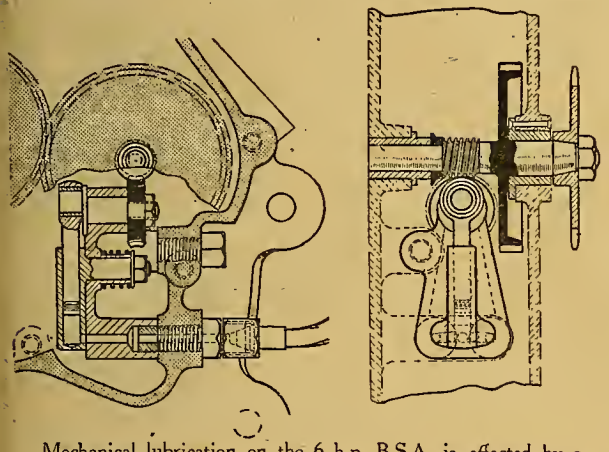
B.S.A., Nos. 75 and 188.

6-7 h.p. V twin four-stroke MODEL: 76×85 mm. (770 c.c.); side-by-side valves; Amac carburetter; E.I.C. magneto, chain driven; three-speed constant mesh gear; chain drive; 28×3in. tyres; detachable wheels.

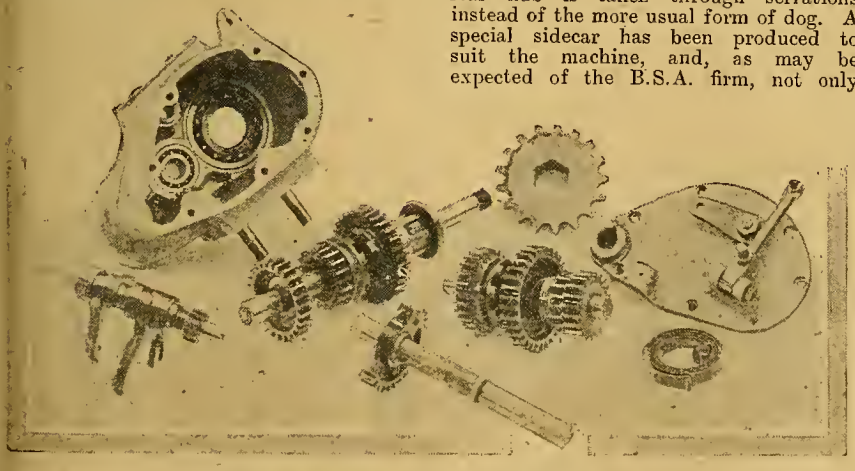
BIRMINGHAM SMALL ARMS CO., LTD., Small Heath, Birmingham.—One of the best designed additions to the sidecar class of motor cycle is the new 6 h.p. B.S.A., which is exhibited to the public for the first time at Olympia. The twin engine is a fine piece of work, with well thought out valve gear and ports, and in the timing case is incorporated a neat oscillating oil pump, which delivers oil to a distributing arrangement, whereby the front cylinder is assured of sufficient lubrication under all circumstances. In front of the engine is a large aluminium silencer with ample provision for cleaning, and above this is placed the E.I.C. magneto. Directly behind the saddle tube is a three-speed constant mesh gear box, in which is comprised robust kick starter mechanism. This gear box is a redesign of that already associated with B.S.A. practice. It is well carried out, and the engine may now be started in the neutral gear position. As is now almost the usual practice, the chain drive is entirely enclosed in aluminium cases, but special precautions have been taken to avoid inaccessibility. Mudguards of exceptional width are employed, and the edges are rolled over so as to form channels to lead away liquid mud. The B.S.A. spring fork has been somewhat modified to suit this model, and a single long compression spring is now used in place of the short compression spring and recoil spring. A very neat and efficient spring saddle-pillar is employed in lieu of spring frame, and quickly detachable wheels are fitted throughout. This last feature has been extremely well executed, and the drive from the sprocket to the rear hub is taken through serrations instead of the more usual form of dog. A special sidecar has been produced to suit the machine, and, as may be expected of the B.S.A. firm, not only is the chassis of extremely stout construction, but the finish is of the highest quality. Springing and upholstery are excellent, and there is ample room behind the seat for a petrol can and quite a large amount of luggage. The brakes fitted are of the rim type, a rim being attached to each wheel to render them interchangeable.

A newcomer in the twin-cylinder field is the 6 h.p. B.S.A., which has enclosed chain-drive and interchangeable wheels.

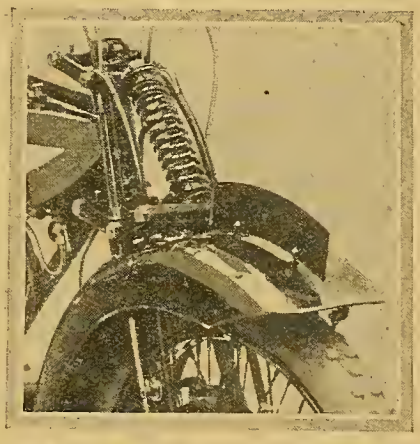




Mechanical lubrication on the 6 h.p. B.S.A. is effected by a small oscillating pump driven by skew gear from the half-time wheel.



The 6 h.p. B.S.A. gear box dismantled. The central member in the foreground is the kick-starter segment, which has a spring tooth.



A redesigned spring fork, on the B.S.A. on which is used a single coil spring of ample strength.

4¼ h.p. single four-stroke MODEL: 85×98 mm. (557 c.c.); side-by-side valves; B.S.A. carburetter; chain-driven magneto; three-speed sliding gear; chain drive; 26×2½in. tyres.

The 4¼ h.p. B.S.A. sufficiently distinguished itself by carrying off the team prize in the 1919 A.C.U. Six Days Trials. Beyond this it is hardly necessary to go any further, as it attracted so much attention through this performance that there are few who are not familiar with its details. The machine may be obtained either with all chain or chain and belt drive, but the main details of each type are similar. It follows the accepted lines of big single-cylinder engined machines, and is extremely well fitted throughout, both as regards mudguarding and accessories. The chains also are carefully protected. Brakes, front and back, are of

The Olympia Show.—

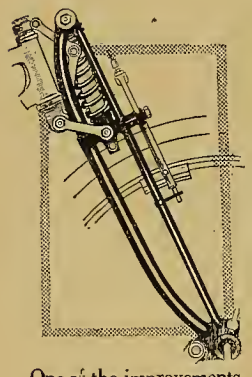
the internal V type, acting in dummy belt rims, and lubrication is through a sight feed drip.

The 3½ h.p. model B.S.A., having a bore and stroke of 85×89 mm., will now only be supplied in T.T. form, with a direct belt drive, and footrests in place of footboards. This is a fine example of a sporting machine, and will attract the attention of many solo riders.

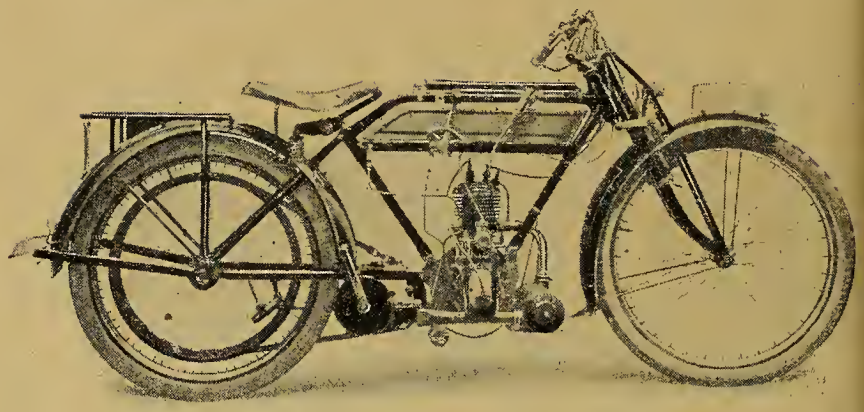
CHATER-LEA, No. 83.

8 h.p. V twin MODEL: 85×85 mm. (964 c.c.); side-by-side valves; Amac carburetter; chain-driven magneto; three-speed sliding gear; chain drive; 700×80 mm. tyres.

CHATER-LEA, LTD., 74-84, Banner Street, E.C.1.—The Chater-Lea exhibit consists of two lightweights, the No. 7 sidecar outfit, samples of the Chater-Lea engine, the new Chater-Lea spring forks, the Chater-Lea seat-pillar, and various fittings and components, including the Chater-Lea terminal. Few sidecar outfits have met with greater success in this country than the No. 7 type Chater-Lea. So satisfactory has this machine been that its makers have wisely refrained from altering it to any great extent. For the first time it is shown fitted with a single-lever carburetter, while the improved detachable wheel, illustrated in *The Motor Cycle* of November 20th, is an important improvement. The fixed portion of the wheel carrying the chain sprocket also comprises the brake drum, and the detachable portion engages with the latter by means of studs.



One of the improvements on the 2¾ h.p. Chater-Lea for 1920 — a redesigned spring fork.



A newcomer in the motor cycle field, the 2¼ h.p. two-stroke Hoskison.

The whole idea is very well carried out in a practical manner.

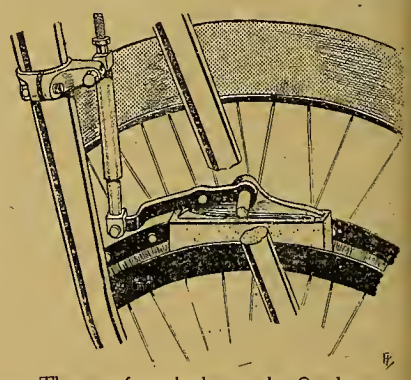
2½ h.p. two-stroke MODEL: 70×70 mm. (269 c.c.); Amac carburetter; M-L chain-driven magneto; two-speed sliding gear; chain and belt drive; 26×2in. tyres.

This exceedingly attractive little lightweight is fitted with a Villiers engine and Chater-Lea two-speed gear box. In addition to the detachable rear wheel dealt with in *The Motor Cycle* of November 20th, another interesting feature is the new Chater-Lea spring forks, which are strong and well-designed somewhat on the lines of the larger model.

HOSKISON, No. 26.

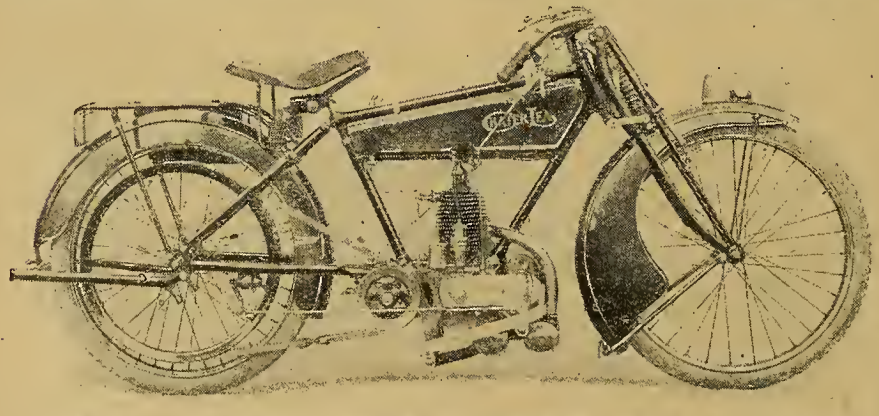
2¾ h.p. single-cylinder two-stroke MODEL: 70×76 mm. (292 c.c.); B. and B. carburetter; Runbaken magneto, direct driven; Burman two-speed gear; chain-cum-belt drive; 26×2¼in. tyres.

HOSKISON MANUFACTURING CO., LTD., 20, Digbeth, Birmingham.—The Hoskison Manufacturing Co. pin their faith to one type of motor bicycle, of which two examples are shown. Of these, one is fitted with disc wheels, and has a very attractive appearance. The 2¾ h.p. Hoskison is an extremely sensible lightweight, built up of the best components, but not possessing any very startling features. Its motive power is a Union two-stroke engine, while the transmission is chain-cum-belt, and the gear box is the Burman, incorporating a clutch and kick starter. The front forks are of the Saxon type, but fitted with Terry's links, and the mudguards are of 7in. section, with splashguards on both. The machines are



The new front brake on the Quadrant.

finished in black with French grey tank, lined in black, grey, and gold, and the manufacturers expect to produce them in considerable quantities. The price of the machine, with Dunlop belt, Lycett pan-seat or All-All saddle, rubber-covered footrests, semi-T.T. flat or upturned handle-bars, is 65 guineas.



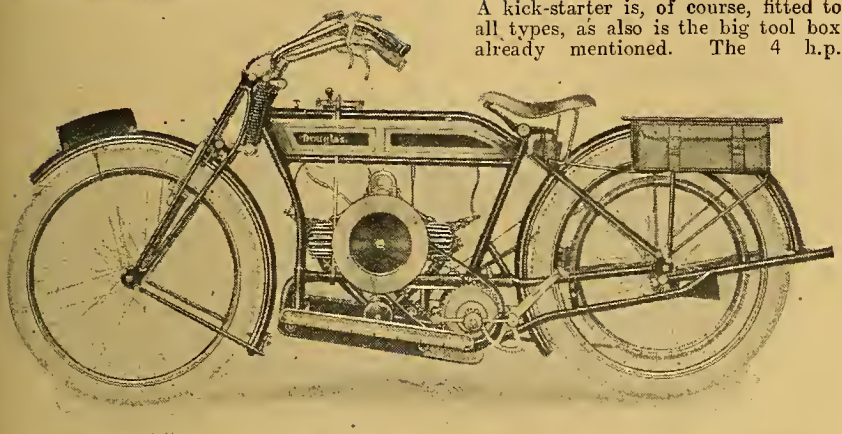
Appearance and serviceability have been carefully studied in the Chater-Lea 2¾ h.p. two-stroke. Note the improved straight-tube frame.

DOUGLAS, No. 76.

2¾ h.p. flat twin four-stroke MODEL: 60.9×60 mm. (350 c.c.); side-by-side valves; Amac automatic carburetter; E.I.C. gear-driven magneto; three-speed sliding gears; chain and belt drive; Clincher 26×2¼in. tyres.

DOUGLAS MOTORS, LTD., Kingswood, Bristol.—The popular 2¾ h.p. Douglas has been largely redesigned for the 1920 season. At first sight the alterations are not very apparent, but on closer inspection it will be found that a modified form of frame has been fitted, which permits the use of considerably wider guards, and a new tank, having rounded top edges, provides a pleasing appearance. The

The Olympia Show.—



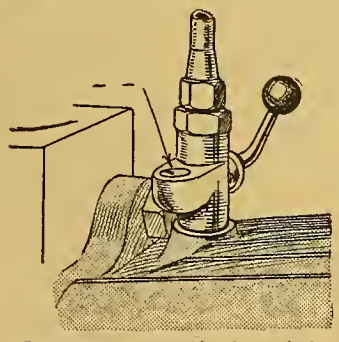
Although its main lines remain unaltered, the 2¾ h.p. Douglas has many detail improvements. Three-speed gear, clutch, and kick-starter are now fitted.

forks also are considerably wider and stouter, and the links are adjustable for wear. The 2¾ h.p. engine remains practically unaltered, but this type of machine is now fitted with a three-speed countershaft gear and clutch as standard. A heavier chain transmits the power from the engine to the gear box, the pitch being ⅝in., and the width of the roller ¼in. A new silencer is fitted below the engine, and has a pipe extending beyond the rear spindle, where a fish-tail end completes the arrangement. The spring forks are lubricated by grease cups throughout, and a new carrier with a very large tool box is now standard. A foot brake, acting above the chain stay and on the inner V of the belt rim, is provided, and a large underscreen not only saves the engine and gear box from mud, but helps to prevent belt slip and keeps the rider clean, assisted by neat brass-edged footboards. The 2¾ h.p. model represents a most practical "go anywhere" touring machine of medium weight, and its popularity, already great, will be largely enhanced by the latest improvements. This machine, together with the 4 h.p., will form the main production programme of the Bristol firm.

4 h.p. flat twin four-stroke MODEL: 74.5×68 mm. (593 c.c.); side-by-side valves; Amac automatic carburetter; E.I.C. gear-driven magneto; three-speed sliding gears; chain and belt; Clincher 26×2⅜in. tyres.

The already well known 4 h.p. Douglas has undergone practically no alteration, except for the fork improvements, already described in the 2¾ h.p. The side-by-side valves lie above the cylinders, and mechanical lubrication is employed, oil being pumped from a sump in the crank case to troughs below the big ends, and also to the front cylinder. The gear box is similar to that of the 2¾ h.p., and the clutch, which is also similar, is of the Ferodo dry-plate type, controlled from the handle-bar. It should be mentioned that, owing to the special arrangement of the clutch spring, which works through a simple system of levers, the pull required to release the clutch is remarkably light. On one model is shown a particularly neat form of dynamo installation.

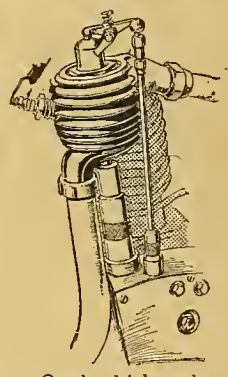
A kick-starter is, of course, fitted to all types, as also is the big tool box already mentioned. The 4 h.p. Douglas is a fine sidecar machine, and has earned its reputation largely through war service. A feature of the new Douglas motor cycles is that malleable lugs have been entirely replaced by steel stampings.



Priming taps near the base of the cylinders are fitted to the 3½ h.p. Douglas.

3½ h.p. flat twin four-stroke MODEL: 68×68 mm. (500 c.c.); side-by-side valves; Amac automatic carburetter; E.I.C. gear-driven magneto; spring frame; three-speed sliding gears; chain and belt; Clincher 26×2⅜in. tyres.

An exhibit which creates a great amount of interest on the Douglas stand is the new spring frame 3½ h.p. This is, to a certain degree, an experimental model, and will not be sold to the public until 1921. The engine, in main features, is a large replica of the 2¾ h.p., but is provided with an oil pump, which supplies oil to the front cylinder through a sight feed drip. Roller bearings are fitted to the big ends, and the magneto, which, as is usual in Douglas practice, lies on the top of the crank case, is held in position by a horseshoe frame and distance pieces. This renders the whole magneto extremely accessible, as it is driven through dogs, and can be removed or replaced without disturbing the timing. From our own experience we can state that the spring frame is most effective. It is controlled by means of enclosed coil springs under the tank through a simple system of links, and, should wear occur, this is readily taken up. So neat is this frame that the casual observer may be forgiven for failing to notice the springing device. In spite of the fact that many will be anxious to obtain specimens of this model, Messrs. Douglas's policy of thoroughly trying out their new departures before placing them on the market is to be highly commended.

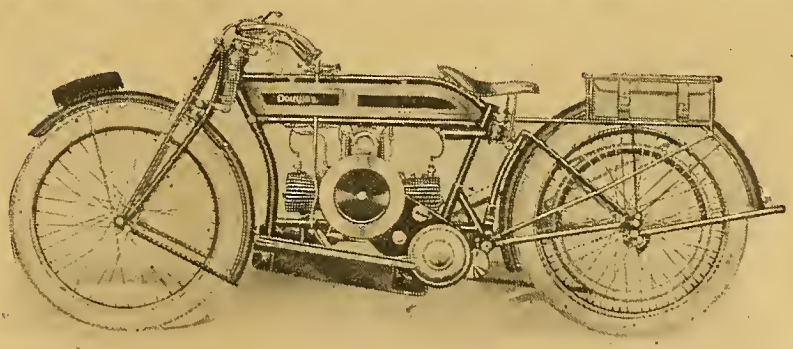


Overhead inlet valve operating gear on the American Excelsior, showing also the enclosed exhaust valve spring.

EXCELSIOR (American), No. 21.

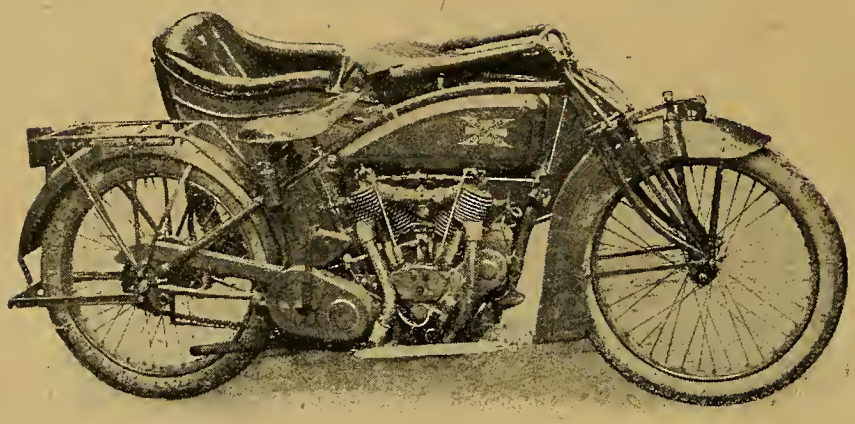
7-9 h.p. V twin four-stroke MODEL: 84.5×88.9 mm. (1,000 c.c.); overhead inlet valves; Schebler carburetter; gear-driven magneto; three-speed sliding gear; chain transmission; 28×3in. Firestone tyres.

MELCHIOR, ARMSTRONG, AND DESSAU (LONDON), LTD., 14 and 14a, Great Marlborough Street, Oxford Circus, W.1.—Two well-known American makes are exhibited on this stand, the Excelsior and the Henderson. Of these, one of each make is an electrically equipped model, and two are standard mounts equipped with sidecars. The various



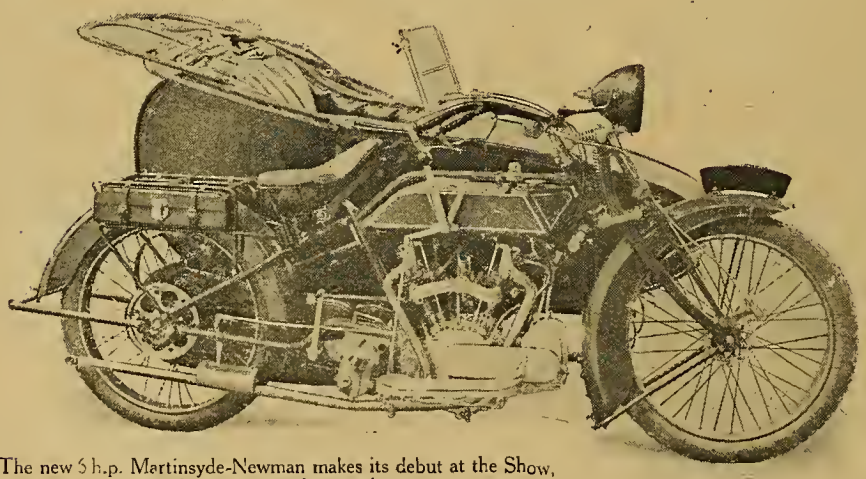
The latest Douglas production—the spring frame 3½ h.p. mount

The Olympia Show.—



One of America's most powerful twins, the 7-9 h.p. three-speed, chain-driven Excelsior.

component parts of these machines are also exhibited. Of these the Excelsior is an attractive V twin, possessing many of the desirable features embodied in motor cycles hailing from the U.S.A., such as automatic single-lever carburetter, mechanical oil pump, and spring seat-pillar. The chief features of the Excelsior, dealing first with the engine, are the overhead inlet valves and the simplicity of the timing gear. The oil tank is carried behind the saddle tube and forms part of the accumulator case. It is of large dimensions, and oil is delivered from it to the crank case by a mechanical pump. It is worthy of note that both the inlet and exhaust valve stems are enclosed. An interesting feature is the fact that the kick-starter is coupled up to the exhaust valve lifter, keeping the valves raised during the whole of the stroke of the kick-starter and dropping them at the right moment. The usual type of three-speed ball bearing gear box and multiple-disc dry clutch running on roller bearings is fitted. It should be noted that the auxiliary horizontal tube of the frame is made detachable, so as to allow the cylinders to be removed without taking the engine from the frame. Features usually associated with American motor cycles, such as 28×3in. tyres, twist grip control, and an electric lighting system are included. The head lug is an excellent piece of construction, and the long curve of the top tube running into the line of the back stays gives a graceful outline that is often lacking in heavy high-powered machines.



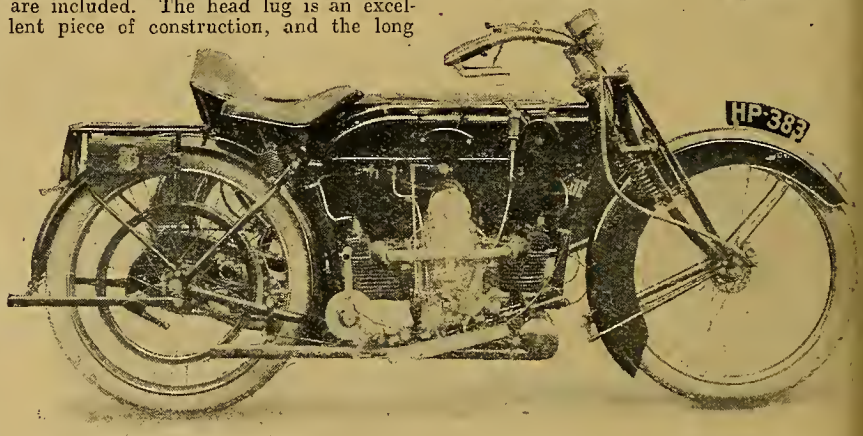
The new 6 h.p. Martinsyde-Newman makes its debut at the Show, and attracts much attention.

The special valve carrier supplied with the Brough machine

HUMBER, No. 85.

4½ h.p. flat twin four-stroke MODEL: 78×68 mm. (600 c.c.); side-by-side valves; Claudel-Hobson carburetter; E.I.C. gear-driven magneto; three-speed sliding gear; chain drive; 26×2½in. Dunlop tyres.

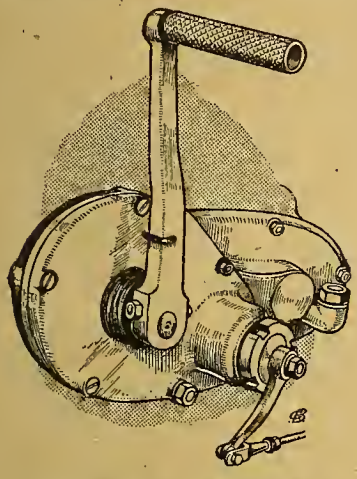
HUMBER, LTD., Coventry.—The motor cycles exhibited on Messrs. Humber's stand consist of two of the new 4½ h.p. flat twin models, one fitted with a fine example of sidecar work. The 4½ h.p. model was described in *The Motor Cycle* of November 13th, and requires little further comment, since its details are already known. It is, to all intents and purposes, a larger edition of the well-known 3½ h.p. flat twin Humber, with one or two slight but important modifications. The valves lie along the tops of the cylinders, and are located in pockets, which can be quickly detached by undoing a single nut and dog. An improvement of some importance in the engine—which, incidentally, shows the trend of modern design—is the incorporation of mechanical lubrication, oil being carried in a sump below the crank case and pumped by a gear pump to troughs below the big ends. From these troughs special dippers on the crank webs pick up the oil and lead it into the hollow crank pins, whence it is thrown to the white-metal-lined big ends by centrifugal force. The gear box has also undergone some modification in that the sliding member now comprises the gear wheels of both first and second speed, the top gear being engaged by means of dogs. Incorporated with the gear box is a neat and substantial kick starter—an improvement on the 3½ h.p. model that will be appreciated by many. A special spring shock absorber is applied to the rear hub, the transmission shocks being



The redesigned flat-twin Humber. The 4½ h.p. engine replaces the original one of 3½ h.p.

The Olympia Show.—

taken by coil springs, and the rebound by rubber blocks. Finished in black relieved by gold lines, the new model has a very attractive appearance, and should be specially suitable for sidecar or fast solo work. The automatic carburetter, which has been a feature of Humber models for some little time, is another item that tends to show the precautions taken by up-to-date designers to simplify the controls.

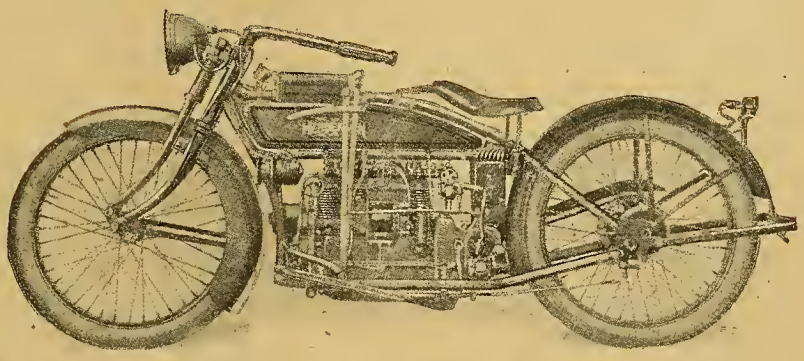


Enclosed kick-starter mechanism is a desirable feature, and a neat example occurs on the 4¼ h.p. Humber.

IVY, No. 91.

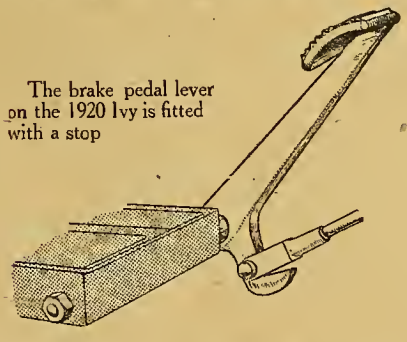
2¼ h.p. two-stroke MODEL: 64×70 mm. (225 c.c.); Amac carburetter; E.I.C. chain-driven magneto; two-speed sliding gear; chain-cum-belt drive; 26×2½in. Dunlop tyres.

S. A. NEWMAN, LTD., Lichfield Road, Aston Cross, Birmingham.—Messrs. Newman's exhibit consists of the one type of machine upon which they are now concentrating their whole attention, namely, the lightweight two-stroke. There are two types of this machine, *i.e.*, the touring models and the T.T. or sporting models. Each of these models is sub-divided into three types, a single-speed, two-speed, and two-speed with kick-starter.



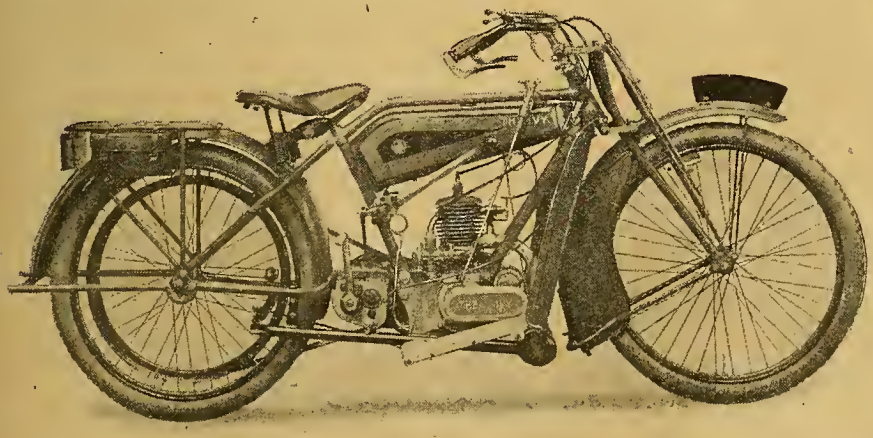
The four-cylinder Henderson; an 8-10 h.p. American machine which has the power unit, clutch, and gear box *en bloc*.

The main details of all these machines are practically the same, and the single-speed model of either type can, if necessary, be converted to a two-speed model, as the frames are identical, and merely the addition of the gear box is all that is necessary. An interesting point with regard to the frame construction is the duplex down tube, which adds considerably to the strength of the machine. The sporting models have discs fitted to the wheels as standard, which give a sporting and neat effect, while all the touring models have ample mudshields fitted to protect the rider's legs. All the machines



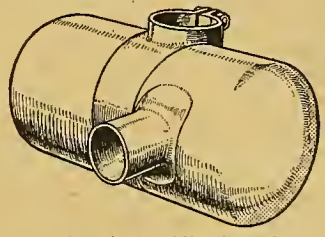
The brake pedal lever on the 1920 Ivy is fitted with a stop

are conventional in design in all other respects, and their appearance with khaki finish, and tank picked out with black panels, gives a very pleasing effect.



Leg shields extending from steering head to footboards add to the efficiency of the new Ivy, a two-stroke of decidedly pleasing appearance.

Another useful fitting is the spring-operated rear stand, which obviates the necessity of fixing this fitting after a stop—a process which is often a muddy and annoying one when short runs in town are undertaken.

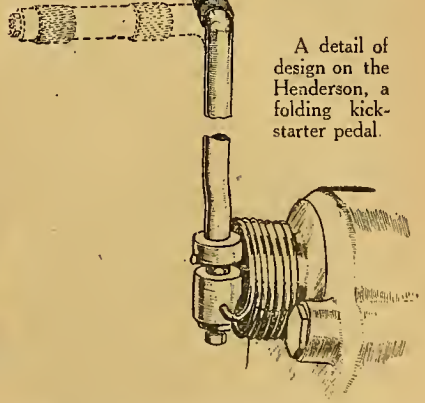


Acetylene welding is used in the production of the one-piece silencer on the Ivy two-stroke.

HENDERSON, No. 21.

8-10 h.p. four-cylinder four-stroke MODEL: 69×76 mm. (1,168 c.c.); overhead inlet valves; Schebler carburetter; Berling gear-driven magneto; three-speed sliding gear; chain drive; 28×3in. Firestone tyres.

MELCHIOR, ARMSTRONG, AND DESSAU (LONDON), LTD., 14 and 14a, Great Marlborough Street, Oxford Circus, W.1.—



A detail of design on the Henderson, a folding kick-starter pedal.

The Henderson is naturally one of the most interesting motor cycles in Olympia because it is one of the only two fitted with a four-cylinder engine at present on the British market. In its thoroughly

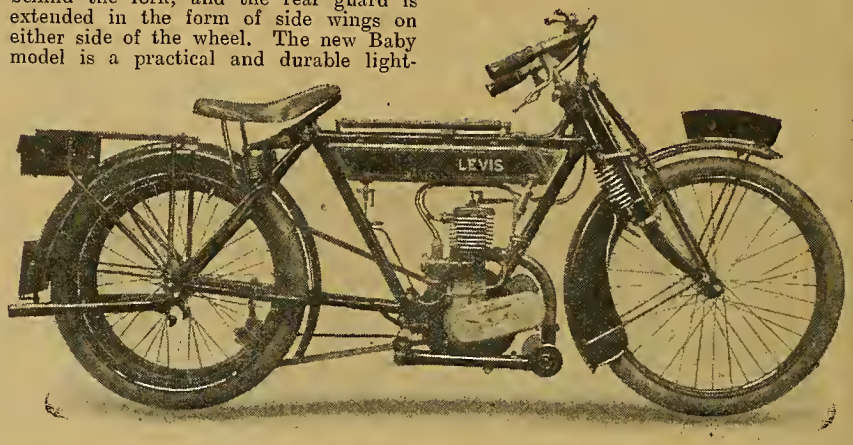
The Olympia Show.—

modernised form with a three-speed sliding type gear box and clutch, all enclosed in a unit with the crank case, the machine is practically a two-wheeled car. The electrical model, fitted with a direct current dynamo manufactured by the General Electric Co. and driven from the timing gearshaft, is one of the most luxuriously equipped motor cycles on the road. An Exide battery is fitted, a genuine Klaxon horn and an ammeter complete the equipment. Points of detail have been well studied; there are spring clips over the lubricating holes in the inlet valve rockers, and adequate means are provided for lubricating the moving parts of the spring forks. The control of the spark and throttle is by twist handle, while it is worthy of mention that the clutch may be actuated by a hand lever, which, when pushed forward as far as it will go, applies the internal-expanding brake in the rear hub, and also by the pedal which controls the clutch alone. The external brake is applied by a pedal. The sidecar model Henderson fitted with acetylene head, side, and tail light, and aluminium disc wheels, is a very handsome outfit. It is equipped with a new pattern luggage-carrier of ample dimensions.

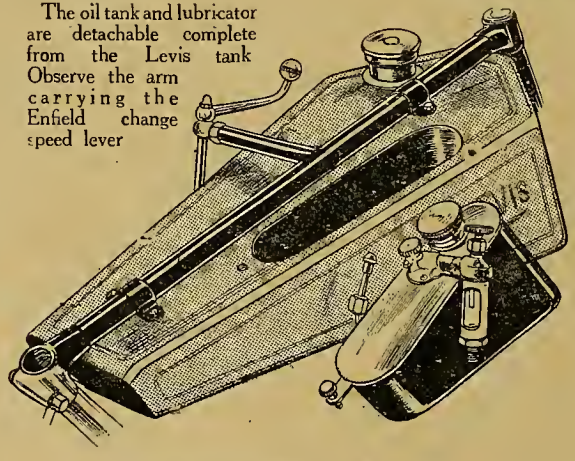
LEVIS, No. 80.

2¼ h.p. two-stroke MODEL: 62×70 mm. (211 c.c.); Amac carburetter; E.I.C. magneto, chain-driven; two-speed clutch gear; chain drive; 26×2¼in. Hutchinson tyres.

BUTTERFIELDS, LTD., Station Road, Stechford, Birmingham.—The new Baby Levis is bound to attract many prospective motor cyclists. Unfortunately, from their point of view, no deliveries are anticipated until the end of the summer at the earliest. This little machine has an engine of the same bore and stroke as the popular model, but roller bearings are fitted throughout the crankshaft. An unusual feature is that the flywheel is arranged on the opposide side to the transmission, which is through an Enfield two-speed gear on the left-hand side of the engine, thus enabling a neat chain case to be fitted, which protects not only the transmission chains, but also the magneto chain. A sloping top tube is used on this frame, and the oil tank is made entirely separate from the petrol tank and is readily detachable should occasion arise. As in the case of the Popular model, the front mudguard is fitted with valances behind the fork, and the rear guard is extended in the form of side wings on either side of the wheel. The new Baby model is a practical and durable light-weight, the performances of the Levis with the Enfield gear having been sufficiently demonstrated in the A.C.U. Six Days Trials.



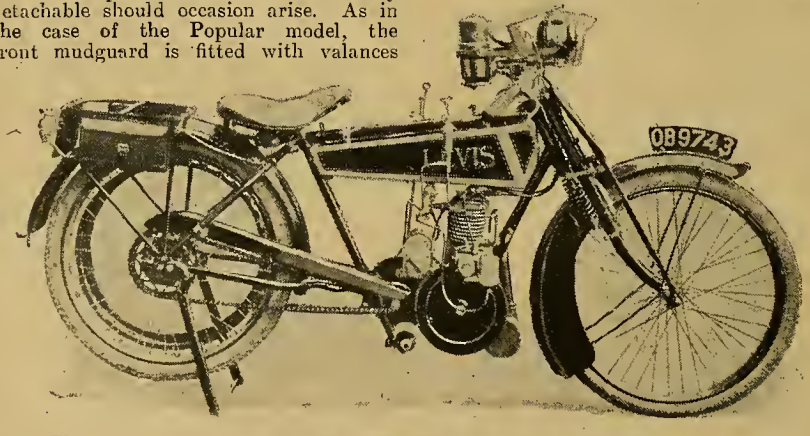
The 2¼ h.p. two-stroke Levis popular model with fixed gear.



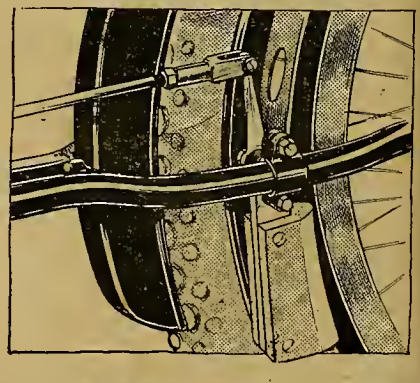
The oil tank and lubricator are detachable complete from the Levis tank Observe the arm carrying the Enfield change speed lever

2¼ h.p. two-stroke MODEL: 62×70 mm. (211 c.c.); Amac carburetter; E.I.C. magneto, chain driven; single gear; 24×2in. Dunlop tyres.

One of the most interesting little machines at Olympia is the standard 2¼ h.p. Levis. This is the case for more than one reason. Its performances are already so well known that there is little or no need for us to enlarge on this important point, for not only in competitions, but also in standard everyday use, the Levis has made its name. However, we wish particularly to emphasise this point: the fact that the little Levis weighs not more than 1 cwt. unladen! This is a very big advance in the right direction, and we are given to understand that even further lightening can safely be carried out, and *will* be carried out in the near future. The Levis three-port two-stroke is one of the forerunners of this class, and its makers still claim it to be one of the best of its type. There are practically no alterations in the 1920 model, except that a new internal V brake is fitted to the rear wheel, and that the tank has been improved in shape and colour, a black panelling now lying on a deep grey background. It is, of course, hardly necessary to state that the Levis lubrication system, in which

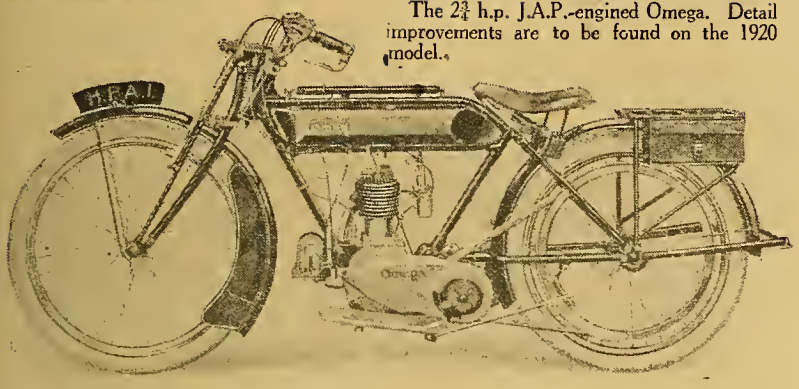


The 2¼ h.p. Levis two-stroke was a forerunner of its type. A sloping top tube and wedge-shape tank have been adopted.



On the Levis lightweight the brake block operates inside the belt pulley as shown

The Olympia Show.—



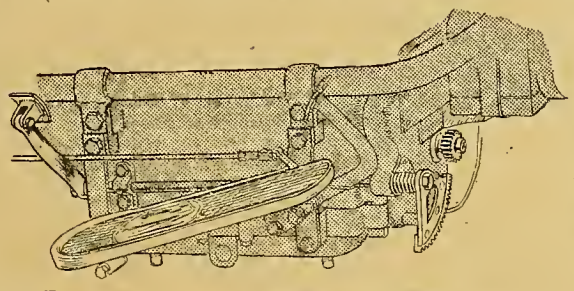
The 2¾ h.p. J.A.P.-engined Omega. Detail improvements are to be found on the 1920 model.

a supply of oil is fed through a sight-feed drip directly to the piston and main bearings, is still incorporated. One other feature of the Levis popular model which is worthy of note is the fact that both petrol and oil pipes are formed of electrically-deposited copper, which form of pipe has been found to withstand vibration better than the more normal type. Brooks saddle and tool-box are now fitted. Levis Popular models are shown with three different types of handle-bars, the up-turned pattern being shown on a machine which is also fitted with a dress guard for ladies' use.

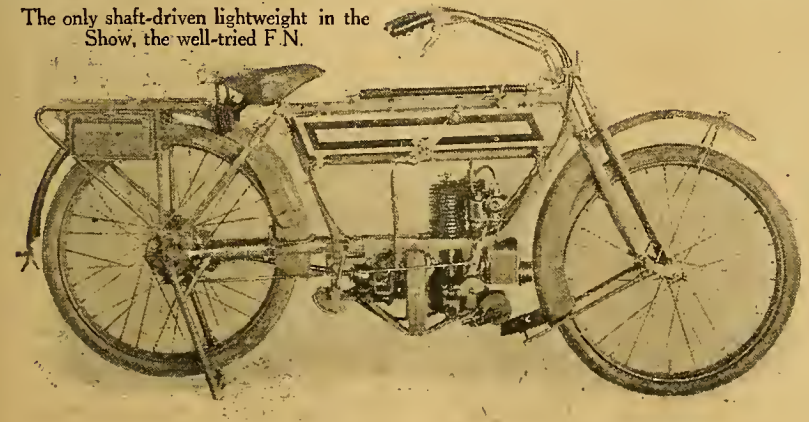
OMEGA, No. 46.

2¾ h.p. single four-stroke MODEL: J.A.P. engine; side-by-side valves; B. and B. carburetter; chain-driven magneto; two-speed constant mesh gear; chain-cum-belt drive; 26×2¼in. Dunlop tyres.

W. J. GREEN, LTD., Hill Street, Coventry.—Six models of the Omega lightweight single-cylinder four-stroke are exhibited by Messrs. W. J. Green, Ltd. These are all fitted with the 2¾ h.p. J.A.P. engine, and vary only in detail, such as handle-bars and gear box. As in the 1914 models, the frame embodies a very substantial one-piece head, and has a curved top tube. As a special attraction on this stand, an Omega with red and black disc wheels is shown. As on several other machines of high-class specification, the Burman gear box is used, controlled by a hand gear lever mounted in a clip on the down tube. The gear box is suspended from a platform which is detachable from the main frame, and forms part of the construction of the rear forks. The machine generally has been improved on minor points, and the equipment now includes the Brampton Biflex forks. Altogether, these machines are exceptionally well finished, and include the minimum of plated parts, the disc-wheeled machine being fitted with bars finished by a new oxidising process which is very durable. Internal cables are used on all Omega models. The rear guard is of 5in. section, and is constructed in one piece; it is also of ample width, and has wide valances. The models are obtainable at the following prices: With two-speed gear and semi-T.T. or touring bars 62 guineas, with kick starter and handle-bar-controlled clutch 71 guineas. This latter model is fitted with a Brooks saddle and larger pannier bags and aluminium footboards.



To devise a kick start mechanism on a shaft-driven four-cylinder machine is not an easy matter, and the F.N. designer has overcome the difficulty in the neat manner depicted above.

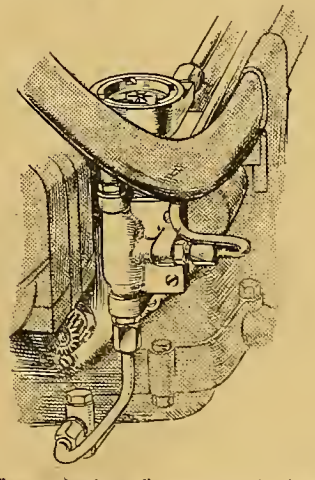


The only shaft-driven lightweight in the Show, the well-tried F.N.

F.N., No. 54.

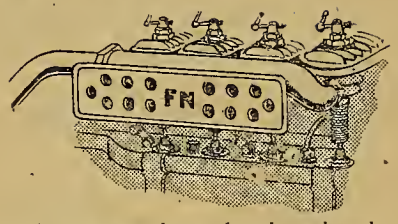
7-9 h.p. four-cylinder four-stroke MODEL: 52×88 mm. (748 c.c.); valves on each side of cylinder; Amac carburetter; Fellows gear-driven magneto; three-speed F.N. sliding gear; shaft drive; 26×3in. Palmer tyres.

F.N. (ENGLAND), LTD., Kimberley Road, Willesden Lane, N.W.6.—Seen for the first time since 1913, the resuscitated four-cylinder F.N. is bound to attract attention, especially as the factory where it is made was one of the first to suffer when the enemy overran Belgium in 1914. The exhibit consists of three 7-9 h.p. four-cylinder machines—one fitted with a sidecar, and three of the 2½ lightweights. The engine has separate T head cylinders with the exhaust valves on one side and the inlet valves on the other. In front, the mechanical oil pump is situated, and above it a lubrication indicator, through the glass in which two small star wheels can be seen rotating so long as the oil flows. The pump serves to draw oil directly from the tank and sump to supply the troughs into which the big ends dip with a constant supply. Oil is also sprayed over the ball bearings of the main shaft and the other principal bearings. Another feature of the engine is the size of the crankshaft, and the flywheel is of ample dimensions in contrast with the earlier models; it also contains a multi-disc clutch. In the beautifully-made gear box car practice is followed; the shafts run on ball bearings, and the moving gear wheels slide on a splined shaft. There is a large circular inspection plate at the side of the gear box. The latest model is fitted with an Amac carburetter—an innovation for this firm—and a Fellows magneto. As soon as deliveries are forthcoming this particular model should be in great demand.



The mechanical oil pump on the four-cylinder F.N

The Olympia Show.—



A trouser guard over the exhaust branch of the new four-cylinder F.N.

2½ h.p. single-cylinder four-stroke MODEL: 65×88 mm. (285 c.c.); side-by-side valves; Amac carburetter; Fellows gear-driven magneto; two-speed sliding gear; shaft drive; 26×2in. Palmer tyres.

In these days when shaft drive is attracting so much attention, considerable interest will doubtless be displayed in the lightweight F.N.—the only lightweight in the Exhibition to be fitted with weatherproof positive transmission. Since exhibited at the last Olympia Show, the lightweight F.N. has undergone very few alterations. It is now fitted with an Amac two-lever carburetter and a Fellows magneto. Its chief features are the rendering of the engine and gear box practically oiltight, and the fitting of a special form of valve cap which cannot come unscrewed. Both valve caps have serrated edges, and when they have been screwed in as tightly as possible with a spanner a bridge piece bolted on to the cylinder head and designed to engage with each valve cap absolutely prevents them from becoming loose. This little machine has been most carefully thought out. The clutch is handle-bar controlled, and in the general arrangement of engine, clutch, and gear, car practice has been followed as closely as possible. A small detail which is worthy of mention is that the oil pump piston, instead of being fitted with the ordinary type of leather washers, is provided with two stepped piston rings.

NEW IMPERIAL, No. 60.

8 h.p. V twin four-stroke MODEL: 85.5×85 mm. (976 c.c.); side-by-side valves; B. and B. carburetter; E.I.C. chain-driven magneto; three-speed gear; chain drive; 28×3in. Dunlop tyres.

NEW IMPERIAL CYCLES, LTD., Princip Street, Birmingham. — Although the New Imperial name is more closely associated with lightweights, the 8 h.p. model, introduced for an Allied Government during the war, is a worthy addition to the New Imperial range. Its design is characterised by sturdy construction, which should render it suitable for the most difficult conditions. One point which is quite apparent is the exceptional ground clearance, which was a necessity for the special purpose for which the machine was designed, and is an admirable point for Overseas conditions. The details of the design appear to be very well carried out. As on the majority of machines of this type, the wheels are quickly detachable, while the mudguarding is ample, and includes an exceptionally wide shield to protect the magneto. The back guard is divided, which allows the rear portion to be swung round for tyre repairs. This rear portion is connected to the frame by a slotted lug and a spring bolt, so that no tools are necessary. Aluminium footboards, Gough pan-seat saddle, two pannier bags, spare tube case, Brampton forks, drip feed lubricator, and metal chain cases form part of the equipment. A De Luxe model includes the Lucas Magdyno lighting set.

ANOTHER ENLARGED ISSUE NEXT WEEK!

The special contents of next week's issue of "THE MOTOR CYCLE" include—

A Review of Sidecar Attachments and Bodywork at Olympia.

Tyres Available in 1920.

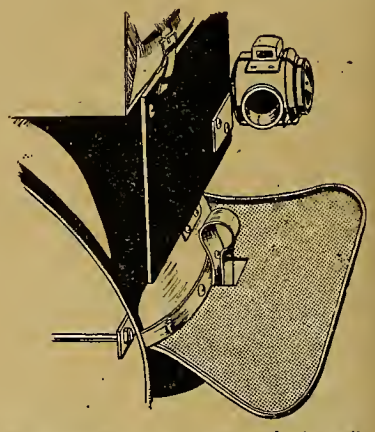
A Survey of the Accessory Exhibits.

Critical Articles on Motor Cycle and Sidecar Design in 1920.

The regular features of this Journal will be retained.

Out on THURSDAY—3d as usual.

The price of the complete outfit, with electrical equipment, is 174 guineas, the motor cycle itself is 118 guineas, and the passenger sidecar 29 guineas. The passenger attachment has an exceptionally large body, supported on an underslung chassis by means of three springs at the rear and long quarter-elliptics at the front. A capacious locker is provided, with door in the rear of the body.



An additional shield extends horizontally beneath the rear number plate of the New Imperial lightweight, thus giving the back of the rider extra protection from mud splashes.

2¾ h.p. single-cylinder four-stroke TOURIST MODEL: J.A.P. 70×76 mm. (292 c.c.); side-by-side valves; B. and B. carburetter; E.I.C. chain-driven magneto; two-speed gear; chain-cum-belt drive; 26×2¼in. Dunlop tyres.

It may be said that the New Imperial-Jap lightweight did more to popularise the small J.A.P. engined machine before the war than any other make, and the new model exhibited at this stand shows evidence that its makers have progressed one step further in producing an all purpose solo machine. The tank has been enlarged and has a capacity of two gallons, which is, perhaps, exceptional on a machine of only 2¾ h.p., and both front and rear guards are of 7in. section—another commendable point on a lightweight machine. The front has a wide splash guard, which should do much to protect the rider's feet and the magneto from wet thrown up from the road, while care has been taken to protect the belt by a gutter fitted round the gap through which the belt passes. This is so designed that water and mud running down the inside of the guard are completely diverted to the side instead of dripping constantly upon the belt. The forks fitted are of the Saxon type, made by the New Imperial Co., and the equipment includes aluminium footboards, large toolbag, Gough pan-seat saddle, and Dunlop belt. The price, with two-speed gear, is 64 guineas, and an alternative model, which has a kick-starter and hand-controlled clutch, is offered at 72 gns.

The 8 h.p. three-speed and the 2¾ h.p. New Imperial models for 1920

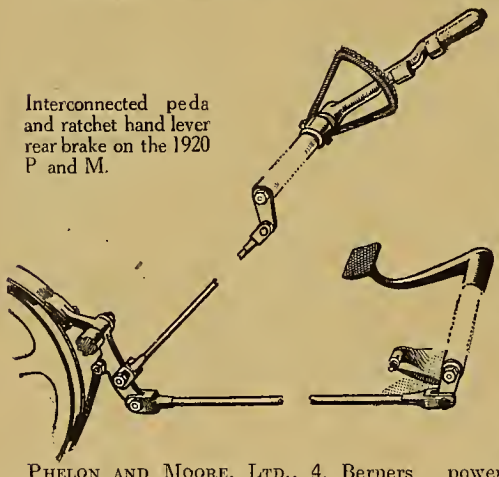
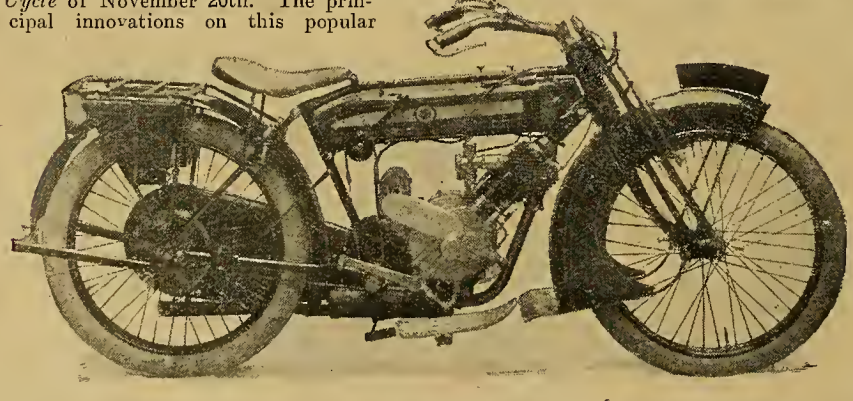
P. and M., No. 63.

3½ h.p. single four-stroke MODEL: 84.5×88.9 mm. (498 c.c.); side-by-side valves; Amac carburetter; chain-driven magneto; two-speed gear; chain drive; Kempshall 26×2½in. tyres.



Interconnected pedal and ratchet hand lever rear brake on the 1920 P and M.

PHELON AND MOORE, LTD., 4, Berners Street, W.1.—The P. and M. exhibit consists of two sidecar and numerous solo machines. A detailed description of the latest model appeared in *The Motor Cycle* of November 20th. The principal innovations on this popular mount are the fitting of an engine from which much greater efficiency can be obtained than before, and the casting of the cylinder fins so that they are parallel with the ground, thus greatly assisting the cooling of the engine, while an extremely interesting innovation is the ingenious oil pump, which conveys the oil alternately to the big end and to the cylinder. Points of convenience have been carefully studied in the latest pattern P. and M. Spacious toolbags are fitted to the luggage carrier and secured by an iron bar, so that they can be effectively locked up, while an extremely comfortable saddle, the nose of which is hinged on to the top tube, is fitted. Messrs. Phelon and Moore were among the earliest firms to consider the fitting of a ratchet brake, so desirable a feature on motor bicycles to which a sidecar is attached, and excellent examples of this brake are to be seen on the P. and M. machines. The firm have long studied the passenger question, and though the P. and M. is of moderate horsepower the machine has acquitted itself extremely well during the war with sidecars attached, and also, of course, as a solo mount. It is extremely gratifying to note that the company have been so far encouraged by the extra efficiency developed in their latest engines that they propose entering for the 1920 T.T. race. The finish of the firm's productions is proverbial, and it would be difficult to find a better finished machine in the exhibition. Messrs. Phelon and Moore are one of the oldest exhibitors, and the fact that their mount retains most of its original features, with up-to-date modifications only, speaks well for the design and reliability of P. and M. motor cycles.

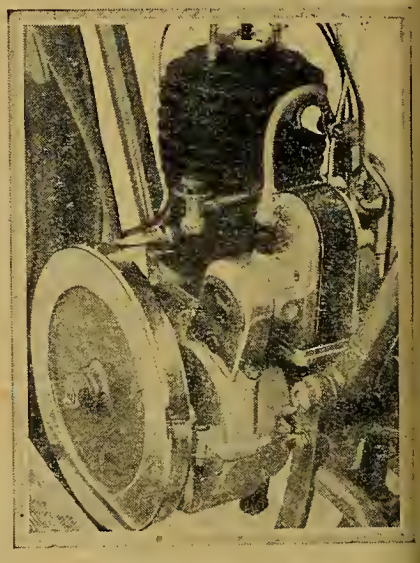


The engine of the popular P. & M. now has horizontal radiating fins and mechanical lubrication.

PARAGON, No. 70.

3 h.p. two-stroke MODEL: 76×79 mm. (349 c.c.); Amac carburetter; gear-driven magneto; two-speed gear; gear and belt drive; 26×2¼ tyres.

PARAGON MOTOR MANUFACTURING CO., Manningtree, Essex—Particularly neat and compact in appearance is the 1920 Paragon motor cycle, in which the gear box is cast integral with the crank case.

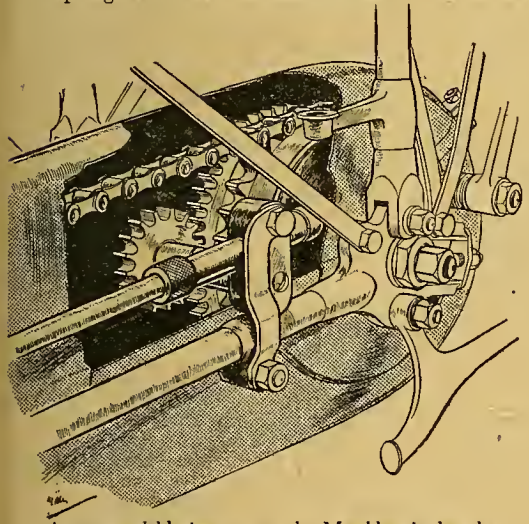


Two-speed gear integral with crank case, a feature of the Paragon two-stroke engine.

The construction is somewhat unusual, as also is the design of the two-speed gear mechanism, in which the driving and driven pinions are constantly in mesh. The gear box is simple in construction and operation; the gear ratios employed are 4¼ to 1 and 7¾ to 1. The 3 h.p. two-stroke engine, which has a bore and stroke of 76×79 mm., follows standard practice. One fitting, however, that has been adopted by this firm since its earliest production, and has been found of considerable utility in separating the inlet and exhaust gases, consists of a small extra air valve, provided with a dust cap, which allows air to be drawn into the transfer port in order that a blast of air may rush out directly this is opened by the descent of the piston. This layer of pure air divides the exhaust and inlet gases, but does not, however, remain in the cylinder to weaken the mixture. It is claimed by the makers that a consumption of 135 miles per gallon has been attained by the use of this device.

The Olympia Show.—

Plain bronze bearings are used throughout, this type being favoured by the makers in consideration of the replacement of spare parts and simplicity in manufacture. The lubrication is of the conventional type, suction feed to the oil grooves in the cylinder walls lubricating the latter, the small end, and the piston, whilst the big end and crankshaft bearings are fed by the usual splash feed. A C.A.V. magneto is mounted on a plate cast integral with the crank case, and is driven through an intermediate pinion, from the low gear driven pinion. Another feature of this machine is the new pattern spring frame—the manufacturer's patent. The rear knock-out axle is secured on either side to sleeves, which reciprocate in the two side tubes forming the main frame of the machine. Between the closed ends of these sleeves and the head of the tube are two springs, the weaker but longer one providing a lively movement for the smaller road shocks, whilst the shorter one of greater strength takes the maximum shocks in order to prevent the complete contraction of the longer spring. A small recoil spring is located at the bottom of the tube, and is held in position by a cap, through which a rod, brazed at the top of the frame member, is passed, and is provided with a nut and washer which locks and encloses the complete spring mechanism. Adequate lubrication is ensured, the sleeves being packed with grease. The rear wheel may be withdrawn without interfering with the brake block or any other fitting. A drop-out axle is also employed on the front wheel, which is sprung by a Brampton Biflex fork. Two brakes are furnished, one on the front wheel rim and the other, which is foot-operated, on the rear belt rim. A standard Amac carburetter is fitted, and fed from the oval tank, which has a capacity of one gallon three pints of petrol and three pints of oil. The price of this mount, which, although equipped with toolbags, is not provided with tools or accessories, is £60.

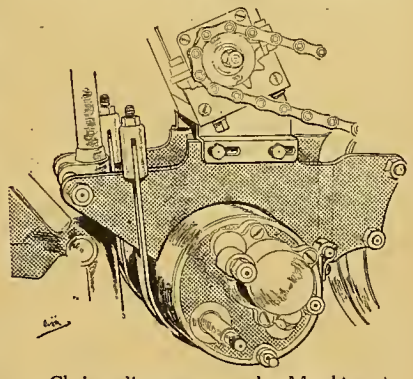


A commendable feature on the Matchless is that the speedometer drive is enclosed within the rear chain case.

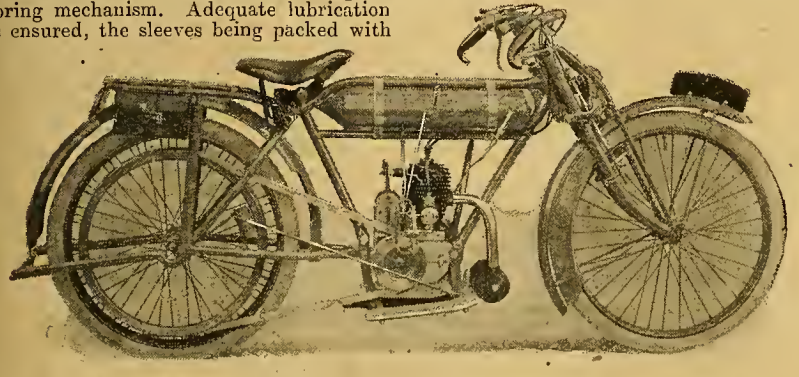
MATCHLESS, No. 48.

8 h.p. V twin MODEL: J.A.P.; 85.5×85 mm. (976 c.c.); side-by-side valves; Amac carburetter; Lucas chain-driven Magdyno; spring frame; three-speed sliding gear; chain drive; 28×3in. Clincher tyres.

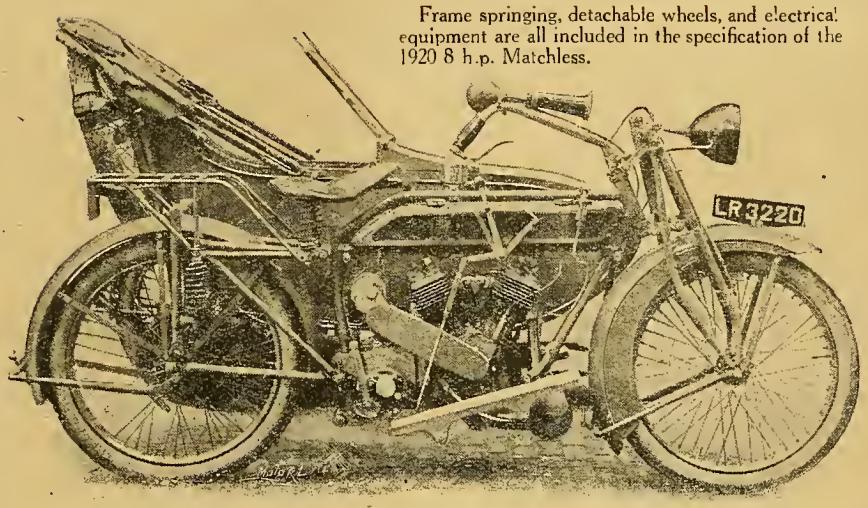
H. COLLIER AND SONS, 44, Plumstead Road, Plumstead, S.E.18.—Described in detail in the issue of July 17th, 1919, the 8 h.p. Matchless sidecar outfit has undergone very little alteration. It is, as its makers have aimed that it should be, the last word in sidecar outfit construction. Excellently sprung fore and aft, the machine is extremely comfortable, and the makers have succeeded in obtaining the maximum amount of ease both for the rider and for the passenger. Two slight modifications have been incorporated in the latest model. The magneto is now carried on a bracket sliding on the top of the engine cradle, which also holds the gear box, so that if the attachment bolts are loosened any slack in the magneto chain may be easily taken up. Another point which is well worthy of examination is the method of driving the Watford speedometer. The driving sprocket of the instrument is attached inside the chain sprocket, and it and the driven pinion are situated inside the oiltight chain case. This ensures the speedometer drive working under the best conditions, since, being entirely protected from the elements, it should last almost indefinitely. The novel method of holding the gear box is also well worthy of mention. The case is round, and is held in steel straps. In the event of it being found necessary to tighten the engine chain, the whole gear box may be moved round to a slight degree after loosening the straps. Messrs. Collier and Sons were the first British firm to interconnect kick



Chain adjustment on the Matchless is easily effected, the gear box being mounted in a tunnel with an eccentric sprocket.



The 3 h.p. spring frame Paragon, which has the gear combined with the crank case.



Frame springing, detachable wheels, and electrical equipment are all included in the specification of the 1920 8 h.p. Matchless.

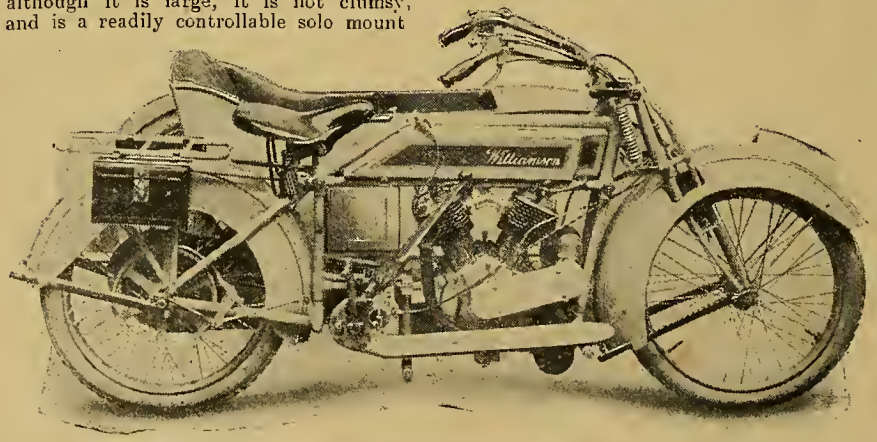
The Olympia Show.—

starter and exhaust lifter. The exhaust valves are raised by means of a cam on the inner side of the kick starter quadrant, which, on the pedal being depressed, comes into contact with a trip on the exhaust lifter arm. The valves remain open during one-third of the quadrant's travel; the trip then slips off the drum, and the valves are dropped exactly at the right moment. A complete engine and gear unit is also shown on the Matchless stand, and affords potential buyers an opportunity more closely to examine these parts.

WILLIAMSON, No. 78.

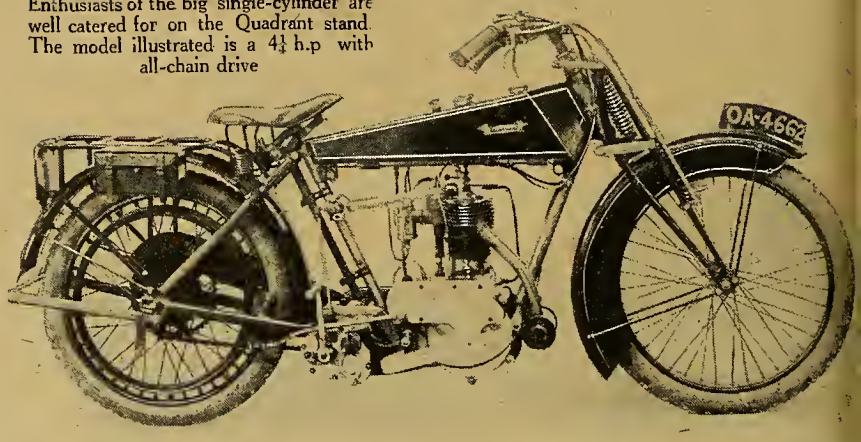
8 h.p. V twin four-stroke MODEL: 76×85 mm. (770 c.c.); side-by-side valves; Amac carburetter; B.L.I.C. chain-driven magneto; three-speed Sturmey-Archer gear; chain drive; 650×65 mm. tyres.

WILLIAMSON MOTOR CO., LTD., Earlsdon, Coventry.—The most notable innovation on the Williamson stand is the new 6 h.p. V type twin fitted with J.A.P. engine and Sturmey-Archer gear. This power plant is neatly fitted into a standard Williamson duplex frame. Transmission throughout is by chain, a spring shock absorber being fitted in the rear sprocket. There are several features of considerable interest on these machines. First, the rear brake is of the contracting band type, standard on Williamson machines, the drum being of exceptionally large diameter. This brake is operated by a pedal having extremely long leverage. The forks are of the Douglas type, and the mudguarding is unusually complete. The aluminium footboards, which are of large size, are sprung at the rear end, and behind the engine and above the gear box is fitted a large accumulator box, which sets off the general lines of the machine in an effective manner. This is an unusual feature, in that the addition of an accumulator box usually renders the appearance of a motor cycle clumsy. Lubrication is through a sight feed drip to the crank case, the internal lubrication being carried out on the well known J.A.P. system. A large silencer is placed in front of the engine, and both chains are protected by covers only, and are not fully enclosed. Fitted with 650×65 mm. tyres, this is an extremely practical sidecar machine, and, although it is large, it is not clumsy, and is a readily controllable solo mount



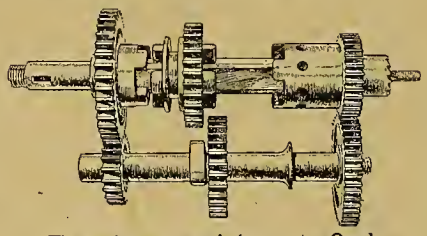
A Williamson passenger machine with duplex frame and the 6 h.p. J.A.P. engine

Enthusiasts of the big single-cylinder are well catered for on the Quadrant stand. The model illustrated is a 4½ h.p. with all-chain drive



8 h.p. flat twin four-stroke water-cooled MODEL: Douglas; 85×85 mm. (964 c.c.); side-by-side valves; Amac carburetter; B.L.I.C. gear-driven magneto; three-speed sliding gear; chain drive; 700×80 mm. tyres.

The standard Williamson production is, of course, represented by the 8 h.p.



The main and lay shafts of the Quadrant gear incorporated with the engine on the new "big single" model. The latter also acts as the camshaft to operate the inlet valve.

water-cooled model. This is fitted with a three-speed gear specially designed for the work, carried in the duplex frame already mentioned, with the exception of the gear box. The engine details are almost exactly similar to those of the 6 h.p. model already mentioned. The clutch in this model is foot-controlled, and the kick starter is of curious but attractive design, in that the rack is internal, and all the framework of the pedal position surrounds the central pinion on the crankshaft. The neat radiators are fitted on each side of the head, and the machine forms a very fine example suitable for heavy sidecar work. A similar air-cooled model is also made, but is not exhibited. Williamson sidecars are, of course, well known, especially for their excellent springing and large and roomy bodies. The chassis design is very stout and powerful, and the sidecar wheel is completely surrounded by a tubular frame, so that the knock-out axle is supported on both sides of the wheel.

QUADRANT, No. 121.

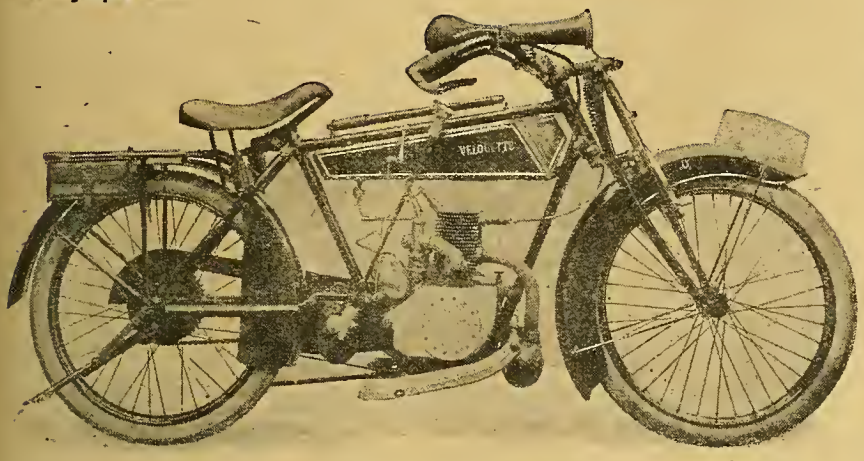
4½ h.p. single four-stroke MODEL: 87×110 mm. (654 c.c.); exhaust valve at side, inlet valve at rear, of cylinder; Amac carburetter; M-L magneto, gear driven; three-speed gear; chain transmission; 26×2½in. Dunlop tyres.

QUADRANT MOTOR CYCLE CO., 45, Lawley Street, Birmingham.—A special feature of the engine is in the distribution gear. A crankshaft pinion drives above it the cam wheel of the side exhaust valve and behind it the gear of a transverse inlet valve camshaft; the latter gear engages with the magneto drive pinion. Thus no idler wheels are required, and a very compact and workmanlike arrangement is attained; in fact, the machine as a whole gives an appearance of neatness which is enhanced by the sloping top tank being of the saddle type and screening the two top frame tubes. The tank is capacious, accommodating 2¼ gallons of petrol and half a gallon of oil. An enclosed chain occurs between engine and gear box, while the rear chain has a full half cover for the top section. Aluminium footplates are standard. The engine valve arrangement is peculiar, for the exhaust is on the right side and the inlet 90° away at the rear of the cylinder.

5 h.p single four-stroke MODEL: 95×110 mm. (780 c.c.); exhaust valve at side, inlet valve at rear, of cylinder; Amac carburetter; M-L magneto, gear driven; three-speed gear integral with crank case; chain drive; 26×2½in. Dunlop tyres.

The design and arrangement of the combined engine crank case and

The Olympia Show.—



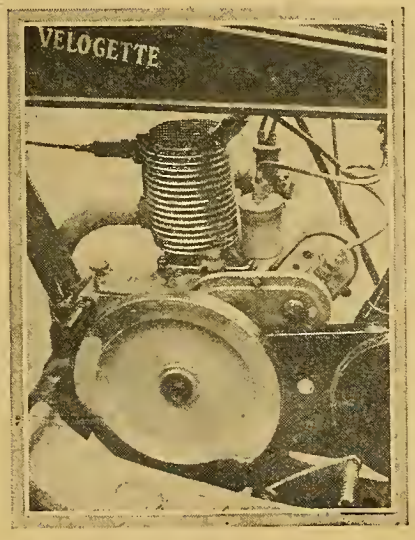
This newly designed Velocette two-stroke should become popular, since on its first competition appearance it won a gold medal in the Six Days Trials.

three-speed sliding gear box are of peculiar interest, for the system eliminates the primary chain. The drive is conveyed through spur gearing from the crankshaft to a layshaft, which also forms the inlet camshaft, the shaft carrying the sliding gear wheels being in the same housing slightly to the rear. The driving chain sprocket is on the end of the last-named shaft, while the clutch is located in the back hub and is of the cone type. Both this model and the 4½ h.p. are suited to sidecar work, the larger especially representing a good example of the powerful single for passenger combinations yet equally fitted for solo work. The examples of sidecars shown attached are all Canoelets with four attachments all held by lugs permanently secured to the frame.

VELOCETTE, No. 19.

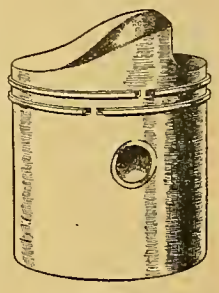
2¼ h.p. single two-stroke MODEL: 62×70 mm. (211 c.c.); Amac or B. and B. carburetter; C.A.V. magneto, gear driven; two-speed sliding gears; chain drive; Dunlop 24×2½in. tyres.

VELOCE, LTD., Sixways, Aston, Birmingham.—With the exception of the three-speed Velocette which gained a gold medal in the Six Days Trial, only one type of this make is to be seen on this stand. An excellently thought-out and useful type of lightweight, carefully designed from stem to stern, it possesses numerous special features such as mechanical lubrication—a point of detail design for which the firm have always been noted. The lubrication is effected



The power unit of the two-stroke Velocette. The cubical capacity of the engine is 211 c.c.

by a pump driven off the intermediate magneto pinion, conveying oil to all the principal bearings. The extremely neat design of the gear box and change-speed lever call for special attention, and are well worthy of careful study. All-chain transmission has been adopted, and in the rear sprocket is a spring shock-absorber and also an internal-expanding brake. By removing a tapered pin in the head, oil may be injected so as to lubricate adequately both head ball races. The frame is extremely strong, the down tube being of the duplex variety and carried right to the end of the engine union as far as the gear box. The space between the rear mudguard and the saddle tube is entirely occupied by a capacious toolbag. Points of detail have been well studied, and the bracket for the generator is brazed on to the side of the saddle tube.



The Velocette piston.

WOLF, No. 118.

2½ h.p. single two-stroke MODEL: 70×70 mm. (269 c.c.); Amac carburetter; M-L chain-driven magneto; three-speed Sturmey-Archer gear; chain and belt drive; 26×2in. Dunlop tyres.

WULFRUNA ENGINEERING CO., LTD., Great Brickkiln Street, Wolverhampton.—Practically, the 1920 model follows the design of that produced this year, no variations of note having been considered necessary. A Villiers two-stroke engine is used with the primary chain of the transmission having a side cover. Druid spring forks are standard, the same applying to the aluminium footboards. The pedal-operated brake follows normal practice, and is applied to the interior periphery of the rear wheel belt rim.

2¾ h.p. single four-stroke MODEL: J.A.P.; 70×76 mm. (292 c.c.); side-by-side valves; Amac carburetter; M-L chain-driven magneto; Sturmey-Archer three-speed gear; chain-belt drive; Dunlop 26×2in. tyres.

This neatly designed solo mount has a J.A.P. engine and Druid forks, the general arrangement of the units being almost identical with that of the 2 h.p. two-stroke model and the largest of the

Two-stroke and four-stroke Wolf lightweights, produced by the Wulfruna Engineering Co., Ltd.

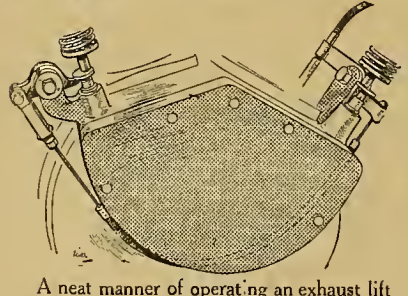
The Olympia Show.—

series, a 4 h.p. type, with a single-cylinder four-stroke J.A.P. engine. The 4 h.p. machine is not, however, exhibited, but it may be said that it forms the model offered for sidecar use. All Wolf machines have a special feature in the reinforcement of the down tube from the steering head to engine bracket; the usual weldless tubes have an inserted flat side plate or web running across the full diameter, and from end to end of the tubes. The carriers of all models are made of ½in. steel tubing, with the stays and struts welded together and in position.

RUDGE, No. 92.

3½ h.p. single four-stroke MODEL: 85×88 mm. (499 c.c.); overhead inlet valve; Senspray carburetter; gear-driven magneto; Multi gear; belt drive; 650×65 mm. Dunlop tyres.

RUDGE-WHITWORTH, LTD., Coventry.—Messrs. Rudge-Whitworth have made no great departure from the general design of their standard models, though many detail improvements may be observed. The famous Multi gear, with which the firm have gained such repute, is still retained on all their models. This gear is too well known among motor cyclists to need detailed description. As most are aware, it consists of expanding and contracting pulleys, the slack of the belt being taken up by the belt rim, also expanding and contracting. The method of changing gear is by means of a long lever at the side of the tank. Its movement from front to back increases the ratio by progressive stages. A point which at once impresses itself on one glancing at these machines is the cleanliness of the crank case, in which all sharp corners have been eliminated as far as possible. this should render the machines extremely easy to clean. A plate clutch is situated on the engine-shaft, and is operated by a Bowden control from the handle-bars. The colour of these machines has also altered since we saw them at the last Show, the tank now being of dark service green with black panels. A good point is the fact that very few bright parts exist, such parts as the handle-bars and hubs being coated with black celluloid. Lubrication on all models is effected by a pump operated by a pedal situated just behind the right footrest. The standard model is fitted with pedals, which, as usual in the Rudge machines, are used for starting the engine. By means of a clever device, one of these pedals may be dropped, thus giving an extra pair of footrests.

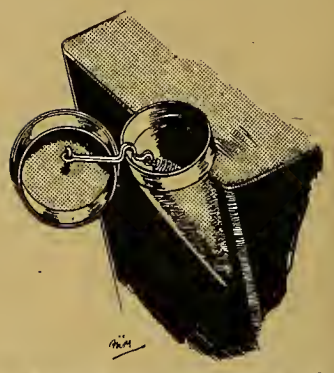


A neat manner of operating an exhaust lift without interior mechanism. The small cable actuated levers on the Rudge Multwin

Another model shown is the famous T.T. machine, which is almost identical in every respect to the one used by Mr. Cyril Pullen when he put up such a magnificent performance, winning the 1914 Tourist Trophy Race in the Isle of Man. This differs from the 3½ h.p. roadster, inasmuch as the frame slopes from the steering head to the saddle, giving a delightfully low riding position. This model also is fitted with a clutch in addition to the multi gear. It has no engine starting device, however, and a pair of fixed footrests are fitted in place of the pedals.

7-9 h.p. V twin four-stroke MODEL: 85×88 mm. (998 c.c.); overhead inlet valves; chain-driven magneto; Multi gear; belt drive; 650×65 mm. Dunlop tyres.

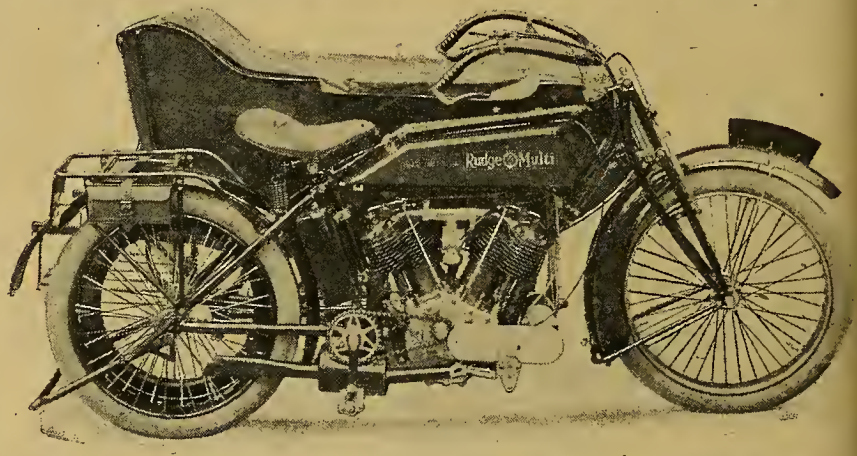
All sporting readers will welcome the new model of Messrs. Rudge-Whitworth, namely, the 7-9 h.p. Multwin, as it is styled. This is a model which was commenced just before the war, and the progress of which, so far as the public is concerned, was cut off by this disaster.



Spring held filler cup on the oil tank affixed to the seat tube of the Rudge

belt drive; 650×65 mm. Dunlop tyres.

A fourth model shown is the long-stroke single, which must appeal to all sidecar enthusiasts who desire a powerful machine of extreme simplicity.

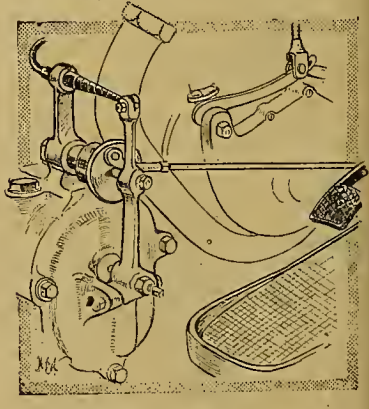


A fast sidecar machine, the 7-9 h.p. Rudge. The Multi-gear and all-belt drive are retained on all Rudge models.

However, tests were continued throughout the war, and the resulting machine is one which will please the eye of all speedmen. In general outline it closely resembles the T.T. model, as it has the same sloping frame. The engine is in many respects a twin replica of the 3½ h.p., having overhead inlet valves, situated directly above the exhausts, and operated by rocker arms and push rods. The magneto is situated in front of the down tube, and is driven by chain. It does not, however, embody the extremely neat vernier adjustment for timing which is characteristic of all the other Rudge models. An inverted Senspray carburetter is fitted compactly between the cylinders. Multi gear is also used on this model, and it has a clutch and the pedal starting device. Two examples of the Multwin are shown, both attached to sidecars, which are manufactured throughout in the Rudge-Whitworth works, and are of very pleasing appearance.

5-6 h.p. single four-stroke MODEL: 85×132 mm. (750 c.c.); overhead inlet valve; Senspray carburetter; gear-driven magneto; Multi gear;

This machine follows the usual Rudge practice throughout, with the exception of the elongated cylinder, which is at once noticeable, and necessitates the tank tube being cranked.



The clutch on the Bradbury has combined hand and foot control, though each may be operated independently

A FINE SELECTION OF TWO-STROKE LIGHTWEIGHTS.

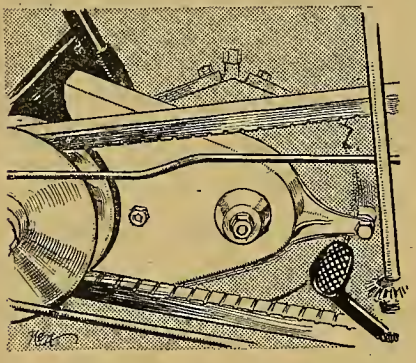
ZENITH, No. 108.

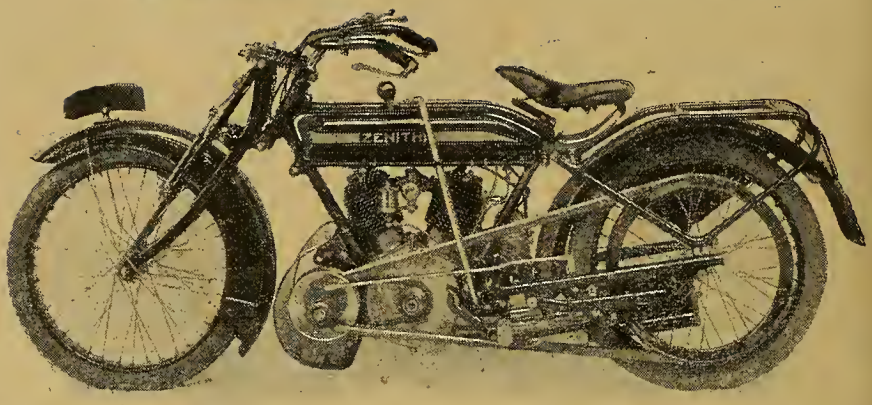
2¾ h.p. flat twin four-stroke MODEL: 58.75×65 mm. (347 c.c.); side-by-side valves; Amac carburetter; C.A.V. gear-driven magneto; Gradua expanding pulley; chain and belt drive; 26×2¼in. Dunlop tyres.

ZENITH MOTORS, LTD., Hampton Court, Middlesex.—This is an entirely new model, and one that should make a very wide appeal to potential motor cyclists. All details of the engine are accessibly arranged; the valves can be removed, ground in if need be without disturbing the cylinders or any other part, while the cylinders themselves can be detached with ease while the crank case remains in position. Hand pump oiling is used. The transmission consists of a chain driving a countershaft immediately below the crank case, and thence by Gradua gear and belt to the rear wheel. The fitting of the countershaft below the engine allows a long belt to be used, the actual length being 7ft. 6in. The belt tension is automatically regulated as the variable pulley is closed or opened out, and in this connection a very ingenious system of pedal brake linkage has been adopted for the 1920 models of all Zenith machines. The brake in question is a pad acting within the belt rim, but, to prevent the brake efficiency and adjustment being upset by the moving back of the wheel centre when the gear is operated, the final motion is conveyed by a



A neat cover is now fitted to the primary chain-drive of the twin Zenith.

vertical member with an open jaw at its bottom end embracing a rod that moves upward when the pedal is depressed. Thus as the wheel centre moves back the brake pad and its immediately adjacent linkage are carried back also, and the open jaw merely slides along the longitudinal rod that moves bodily upward to operate the brake. The countershaft is supported by ball bearings in an aluminium bracket, which in turn is held by bolts passing through slotted holes in the hanging brackets. The chain can therefore be adjusted by a vertical movement that does not affect the tension of the belt. The latter is provided with a limited range of adjustment, which can all be taken up during the course of a run, if need be, without the rider being called upon to reduce the length of the belt until he has time to spare for that process. The engine as a whole is supported above a steel baseplate, which in

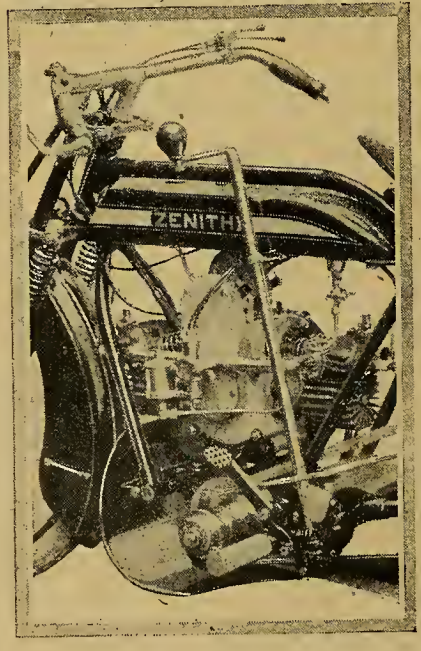


Amongst belt-driven adherents the 8 h.p. Zenith is a popular mount. The well-sprung seat will be particularly noticed.

turn is attached to two tubular cross members of the widely separated tubes depending in pairs from head and seat support. It is by reason of the width between the units of each of the dual tubes that the cylinders can be so easily detached. The magneto is also very accessible, for it is mounted on top of the crank case, below the tank, with its contact breaker arranged conveniently for adjustment on the right-hand side. The magneto chain drive is all enclosed. Wide mudguards are fitted fore and aft, those at the back having a segmental extension at each side reaching from the back stays to the rear end of the carrier.

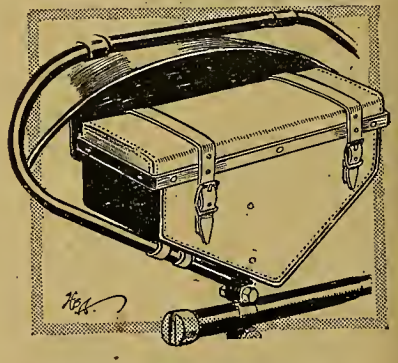
4-5 h.p. V twin four-stroke MODEL: 70×64.5 mm. (496 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett chain-driven magneto; Gradua expanding pulley; belt drive; 650×65 mm. tyres.

The outstanding innovation on this model is the combined carrier and rear



A new model in the Zenith range fitted with a flat twin engine of 347 c.c.

stays, each side of which is formed of two lengths of tubing telescoped over the axle centre line, and shaped to a triangular form in side elevation. A very sturdy construction is thus provided, for the ¾in. diameter side tubes of the carrier are stiffened at two points by brazed-on cross tubes, while the stays themselves are ⅞in. in diameter and have a tubular brace at the top end in addition to the transverse bolt that holds them in position. The unit can be removed as a whole from the main frame without disturbing any other part. The new stand



A capacious toolbag is used on the new Zenith, with separate compartments for spare tube and tools.

is unusual, for it consists of two flat tubular supports hinging together from a lateral bearing near the centre of the machine, the centre line of the bearing being located between engine and rear wheel. The same type of stand occurs on the 8 h.p. model, and both are fitted with J.A.P. engines.

8 h.p. four-stroke twin MODEL: 85.5×85 mm. (976 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett chain-driven magneto; Gradua expanding pulley; chain and belt drive; 650×65 mm. tyres.

The special features of this machine, the chain drive to a forward countershaft and the very long belt to the rear wheel, are continued, the same type of Gradua variable pulley gear being in evidence. But in the machines supplied for combination work a free engine clutch can be embodied. This is a very workmanlike

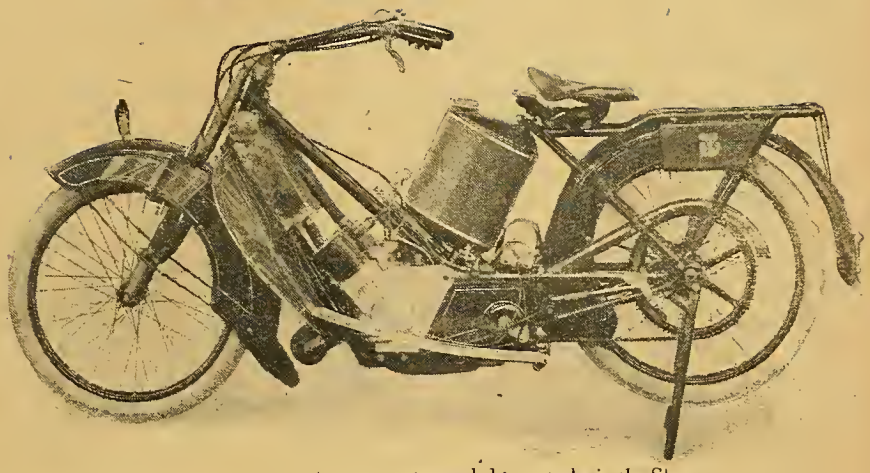
The Olympia Show.—

device, consisting of a combination of friction cone (metal-to-metal, running in oil) and positive dog clutches. The cone takes up the drive smoothly and without shock, but the spring pressure is not sufficient (and is not intended to be) to provide other than a slipping drive, the final upward movement of the clutch pedal allowing the dog teeth to drop into mesh—that is, when the driving and driven members are running at similar speeds. The dog teeth are bevelled on their edges, and have no tendency to overrun and clatter. On this machine, as on all Zenith 1920 models, a new sprung saddle is fitted; its springs are of the leaf type, viz., quarter-elliptics, one of the three supporting the front of the seat and the other two the rear portion. It is a well-conceived design, and one that should be exceedingly comfortable in use without permitting lateral sway and tendency to affect steering. Altogether, the Zenith exhibit presents an exceedingly interesting display, and the machines embody a very great deal of well thought out and practical detail.

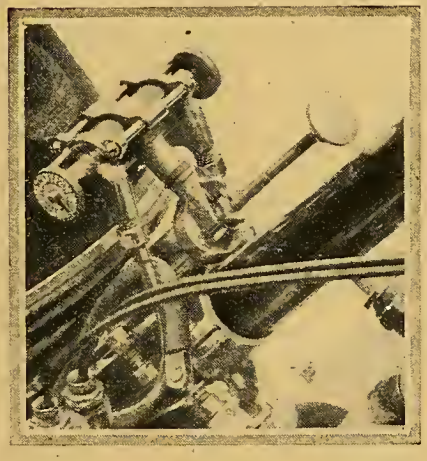
SCOTT, No. 122.

3¾ h.p. twin two-stroke MODEL: Binks carburetter; Thomson-Bennett magneto, chain driven; two-speed expanding clutch gear; chain drive; Palmer 26×2½in. tyres.

SCOTT MOTOR CYCLE CO., LTD., Saltaire, Yorkshire.—Four models are shown, three being solo machines, *i.e.*, the standard touring, another with semi-T.T. bars, and a third termed the sports model, which has a higher gear ratio, full T.T. bars, and narrower mudguards. The fourth type is the sidecar machine, which has 26×3in. Palmer Cord light car tyres, and gear ratios of 4.69 and 8.62, the ratios of the solos being: Standard 4.25 and 7.85, sports 3.75 and 7.2. Variations and improvements for 1920 include wider mudguards (sports model excepted), having an overall width of 5¾in. The rear brake now has a much larger shoe

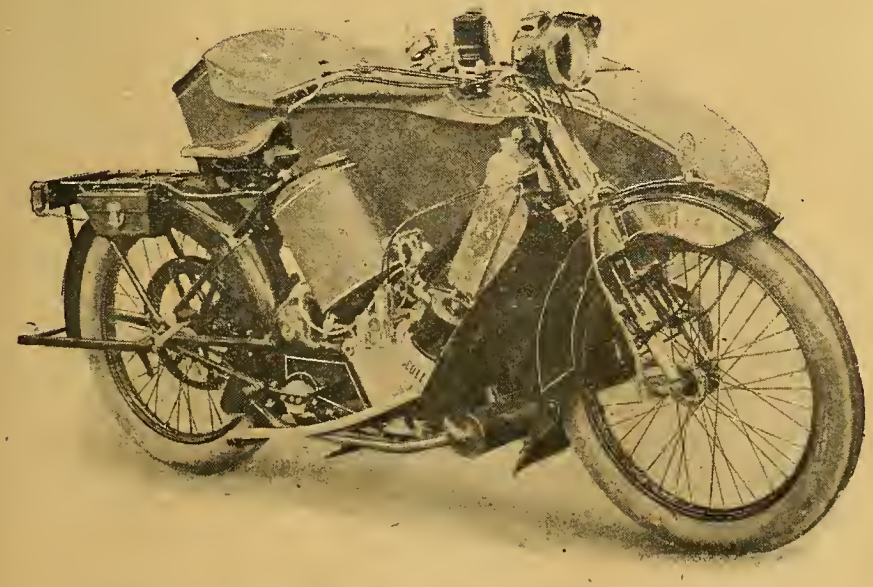


[illegible] water-cooled two-stroke in the Show



The lubrication system on the 1920 Scott embodies a neater form of separate sight feed for each crank case.

operating within the drum formed as a unit with the chain sprocket. A new sight feed for the oil is arranged horizontally, with a glass enclosing the two feeds, one to each of the cylinders; the new arrangement brings the oil feed into direct view when the rider glances down. The honeycomb radiator is wider and deeper, affording a larger area of cooling surface, and the kick starter stop now consists of a rigid lug on the bottom fork tube of the rear wheel. The sidecar exhibited is worthy of careful inspection. The chassis is the Scott patent cantilever type, with all straight tubes and four-point attachment. Coil springs are used at the rear, and are adjustable to suit the weight of the passenger, while C springs support the front of the body. Behind the seat is a covered compartment that will hold a two-gallon tin of petrol, tin of oil, and tools, while under the forepart is a tray for maps, small parcels, etc. On general lines the 1920 Scotts follow the makers' established practice, and that it represents a successful system in principle and construction the recent A.C.U. Trials have given conclusive evidence.



Scott two-stroke sidecar combination for 1920. The efficient guards will be noted

BRITISH EXCELSIOR, No. 51.

2½ h.p. single two-stroke MODEL: Villiers 70×70 mm. (269 c.c.); Amac carburetter; C.A.V. chain-driven magneto; two-speed constant mesh gear; chain-cum-belt drive; 26×2¼in. Dunlop heavy tyres.

BAYLISS, THOMAS, AND CO., LTD., King's Road, Tyseley, Birmingham.—Although perhaps the Excelsior was better known in the larger sizes before the war, the new lightweight models recently introduced bid fair to live up to the reputation created by their predecessors. Of the former, the Villiers-engined two-stroke is an exceedingly taking machine, having a sloping top tube and a wedge-shaped tank holding eleven pints, finished in black with Cambridge blue and gold lines. The forks fitted are larger than is usually the case with lightweights of this type, being of the wide bearing pattern, and the mudguarding is well carried out both front and rear. The former guard has deep valances, and the latter flat extensions on either side, giving altogether a width of 7in. There are very few plated parts on the machine, the bars being enamelled black and fitted with Bowden levers with outside cables.

The Olympia Show.—
The equipment includes two pannier bags with tools, inflator, Best and Lloyd sight feed lubricator, aluminium footboards, Dunlop belt, and Renold chain. The price is £58 16s.

2¾ h.p. single four-stroke MODEL: J.A.P. engine; side-by-side valves; Amac carburetter; E.I.C. chain driven magneto; two-speed gear; chain-cum-belt drive; 2¼in. Dunlop heavy tyres.

This J.A.P.-engined machine is similar in design and equipment to the two-stroke model, and is probably one of the most compact machines of this type. The price is £65 10s., or with hand-operated clutch, £71 10s.

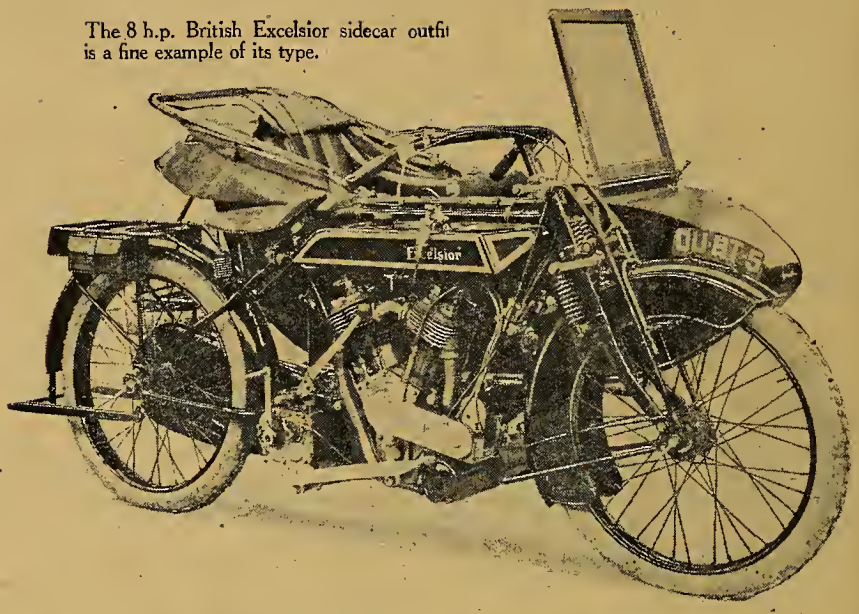
8 h.p. V twin four-stroke MODEL: J.A.P. 85.5×88 mm. (980 c.c.); side-by-side valves; Amac carburetter; M-L chain-driven magneto; three-speed Sturmey-Archer gear; chain drive; 28×3in. tyres.

Our older readers will recall the pre-war hill-climbing expeditions of Mr. W. H. Carson, an enthusiastic sidecarist, who made a hobby of searching for and assailing hills considered to be unclimbable. It has been chiefly from the experience gained

Detachable and interchangeable wheels are a feature of the 1920 8 h.p. British Excelsior.

in these trips and thousands of miles of all-weather driving that the new 8 h.p. British Excelsior sidecar has been evolved.

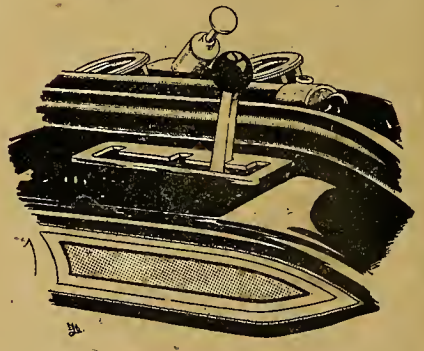
The 8 h.p. British Excelsior sidecar outfit is a fine example of its type.



It is a serviceable model, with 28×3in. quickly detachable and interchangeable wheels, a spare being carried in the underside of the folding grid supported on the back of the sidecar body. Everything is of strong construction, and follows sound commonsense lines. The sidecar is sufficiently long in the body to provide accommodation for a child's seat. This is made to slide upon slotted plates secured to the body and the door respectively, and a hood and screen form part of the very complete equipment. The body is suspended on C springs well extended at the front which should remove the vibration at the feet which is noticeable on some sidecars. The model on exhibition is equipped with a Lucas dynamo lighting set, neatly installed. The generator is clipped to the seat tube of the machine, and is driven by a chain from the outside on the primary drive casing. The dynamo chain is protected by a metal guard. The Excelsior standard model is fitted with a comfortable pillion seat attached to the carrier, upholstered in Bedford cord, mounted on C springs, terminating in coil springs, to which the upholstery fitted is attached. It would be hard to find a more completely equipped sidecar outfit or one constructed on more practical lines. The price of the outfit is £162.

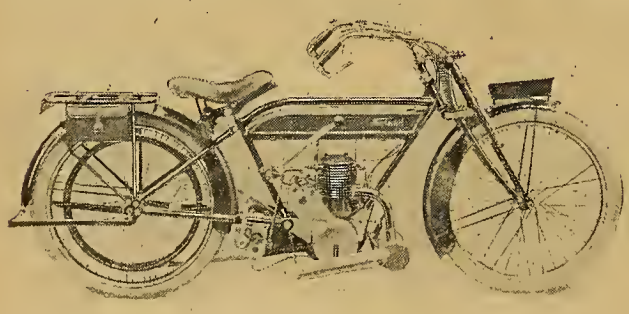
ROVER, No. 79.

3½ h.p. single four-stroke MODEL: 85×88 mm. (499 c.c.); side-by-side valves; B. and B. carburetter; E.I.C. silent chain-driven magneto; three-speed sliding gears; chain drive; 650×65in. Dunlop tyres.

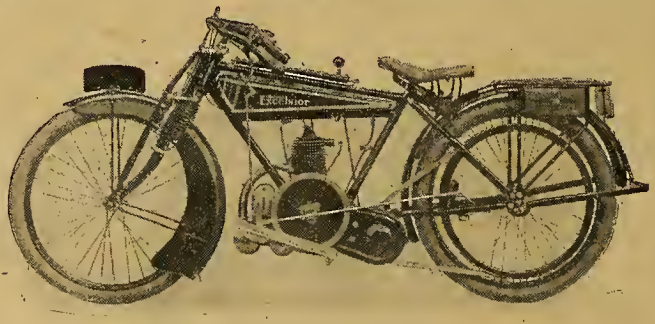


The Rover change speed lever projects through the tank, and is handily situated.

NEW ROVER CYCLE CO., LTD., Coventry.—Very few alterations have been made to the 3½ h.p. single-cylinder Rover. The engine primary transmission of the gear box remains as before, the

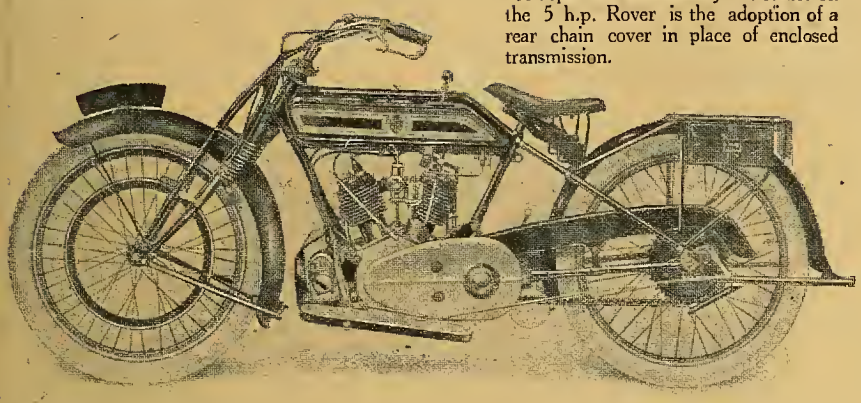


The Torpedo-Precision two-stroke two-speed lightweight.



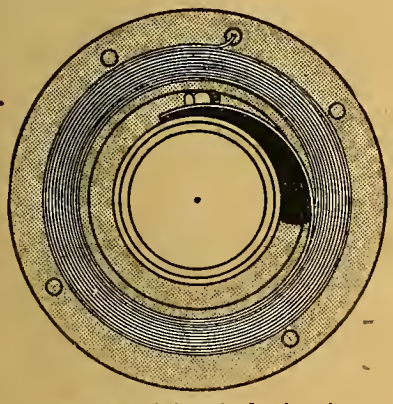
A Villiers engined Excelsior lightweight.

The Olympia Show.—



A departure immediately noticeable on the 5 h.p. Rover is the adoption of a rear chain cover in place of enclosed transmission.

main feature thus far being the silent chain transmission to the gear box. The most noticeable alteration is that the final drive is now carried out through a spring link chain instead of a belt. As in the 5-6 h.p. model, this chain is protected along the upper run only.



A leather bolster is fitted under the end of the governor spring in the Philipson pulley in order to eliminate breakages.

In all its main details this type resembles the 5-6 h.p. excepting for the fact that it is fitted with a single-cylinder Rover engine, which is exceptionally quiet in running, especially as to its valve gear. The T.T. belt-driven models are also shown on this stand. These machines have a similar engine, but the transmission is by belt, either from a plain adjustable pulley or a Philipson pulley. In the case of the Philipson pulley, a very simple hand control may be fitted operated by a small lever on the handle-bar.

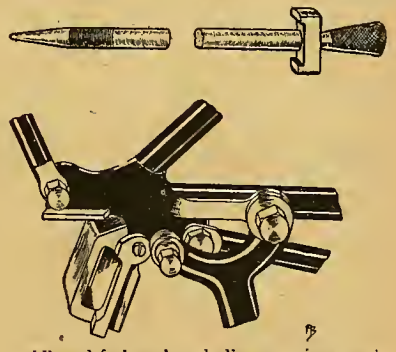
5-6 h.p. V twin four-stroke MODEL: 70×85 mm. (654 c.c.); side-by-side valves; Amac carburetter; E.I.C. chain-driven magneto; three-speed sliding gears; chain drive; 28×3in. Dunlop tyres.

A very fine specimen of a powerful solo or light sidecar machine is displayed on the Rover stand in the new 5-6 h.p. model. There are several extremely interesting features in this machine. First, the primary drive is through a noiseless chain, neatly enclosed in an aluminium case, the final drive being of the spring link type chain so long associated with Rover practice. This chain is protected by a guard along the upper run, the guard being extended over a considerable depth on each side. Very simple and positive adjustment for the tension of the final chain is provided in a notched quadrant, which makes it very easy to keep the wheel in line. The gear box is of sturdy construction, having an entirely enclosed kick-starter. The clutch is of the dry-plate type, and is operated by a pedal on the right-hand side of the engine. The gear box is provided with an unusually large inspection cover, through which it may be filled with lubricant. An internal-expanding brake is fitted in the rear sprocket, and the rotation of the front wheel can be controlled by a shoe acting in the V of a dummy belt rim. Forks of the Druid type are fitted, and spring top fork links are used, very wide flat mudguards being provided for each wheel. These guards are rolled over at the edges to form a small valance, and the back part of the rear guard can be removed for the purpose of tyre inspection. A large splash shield protects the magneto and the front part of the engine from any mud which might escape from the front guard, and a particularly neat round-edged petrol tank, through which the gear striking lever projects, is carried in the dropped top tube of the frame. Following Rover custom, the oil tank is of circular formation, and is let into the petrol tank in such a way that the oil pump is fixed on the right-hand side and projects in a convenient manner. Metal-beaded footboards complete the main specification of this machine, though the large aluminum silencer should not be forgotten, as Rovers are notably silent on the road. Attached to the 5-6 h.p. Rover is a fine sidecar beautifully upholstered and finished in grey. A wide flat guard, similar to that on the motor cycle, protects the passenger from mud from the sidecar wheel, and the chassis, which includes a sidecar stand, is simply and strongly constructed. One feature of considerable importance is the method of supporting the mudguard to prevent rattle. This is carried out by stout tubular stays which are perfectly rigid.

BAT, No. 82.

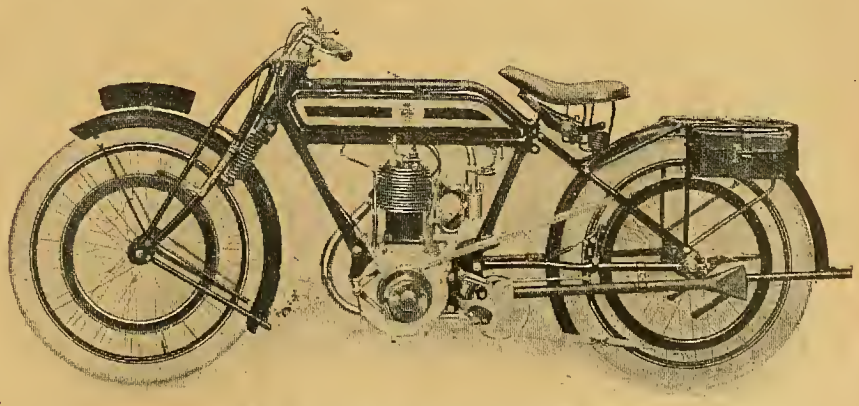
8 h.p. V twin four-stroke MODEL: 85.5×85 mm. (980 c.c.); side-by-side valves; Amac carburetter; C.A.V. magneto, gear driven; three-speed sliding gear; chain drive.

BAT MOTOR MANUFACTURING CO. (1918), LTD., 2, Kingswood Road, Penge, S.E.20. —A noteworthy feature of the 1920 8 h.p.



Hinged fork end and distance piece used in connection with the Bat detachable wheel. It is locked by a dog on the knock-out spindle

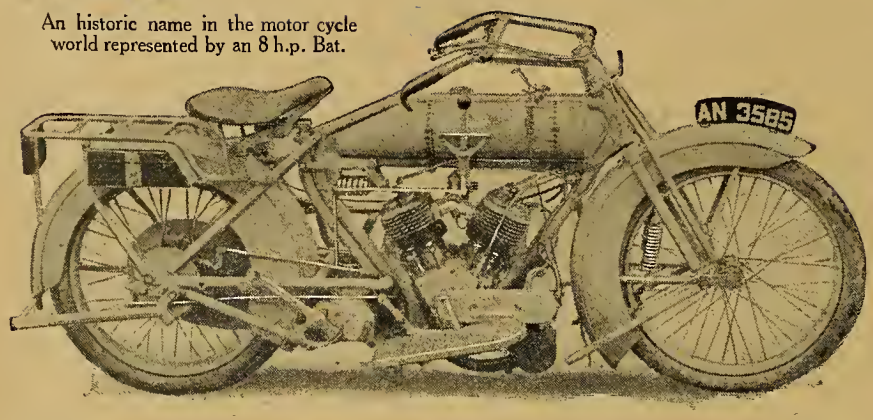
Bat machine is, in addition to its general robust construction, the ingenious design of the rear detachable hub. An advance upon previous design has been made, inasmuch as no loose distance pieces are used. These have been superseded by a fixed distance piece, hinged to the rear fork



Speed men are catered for in the 3½ h.p. Rover T.T. model, which is fitted with hand-controlled Philipson pulley.

The Olympia Show.—

An historic name in the motor cycle world represented by an 8 h.p. Bat.

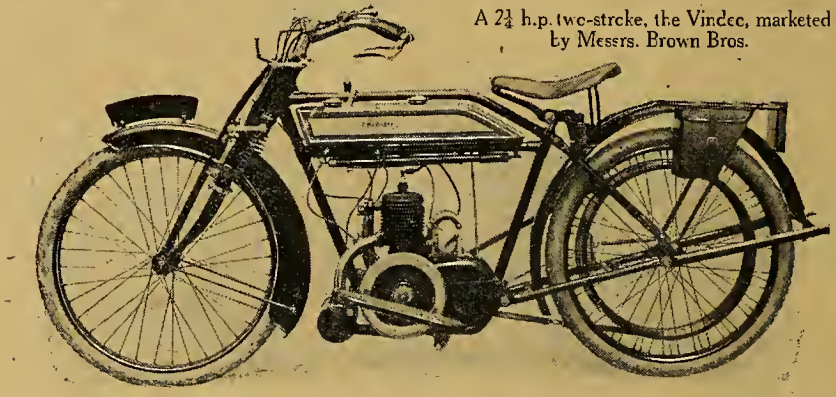


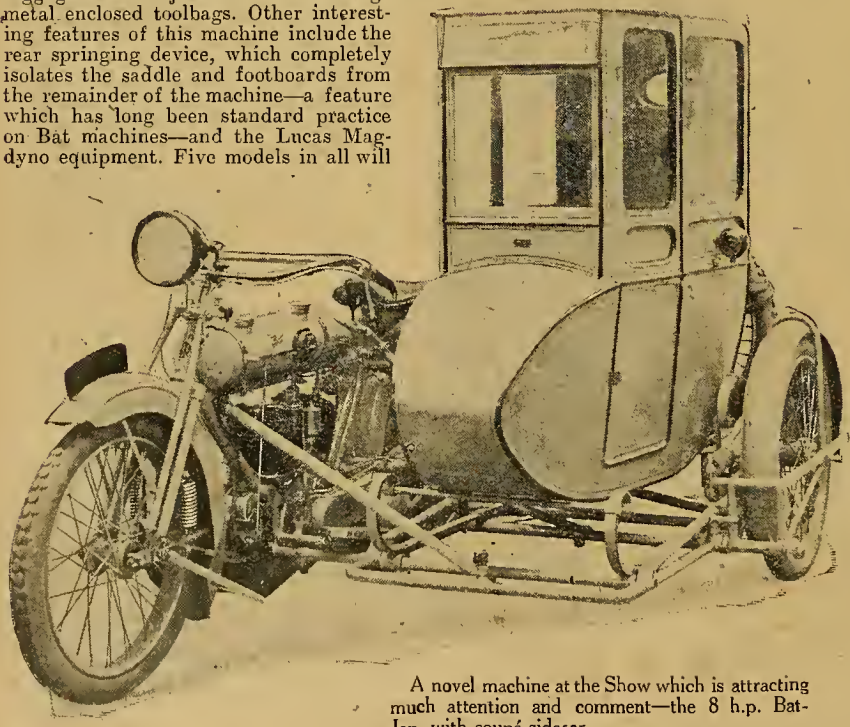
end, and provided with a longitudinal slot to accommodate the knock-out spindle. The head of the rear spindle is provided with a steel washer, which, when the wheel is in position, locks the flange on the distance piece rigidly to a similar flange on the rear fork end. This method of locking makes the usually tiresome duty of changing a wheel a very simple and rapid operation, as the removal of one nut on the near side of the spindle permits the removal of the bolt which automatically releases the hinged distance piece, when the wheel may be taken out. The drive from the rear chain sprocket, in which an internal expanding brake is located, to the wheel hub is transmitted through substantial dog teeth, cut externally on the former, which engage with similar teeth cut internally on the latter. In order to facilitate the removal of the wheel, the rear mudguard is capable of being lifted up, and this is effected by withdrawing a long bolt beneath the luggage carrier just behind the large metal enclosed toolbags. Other interesting features of this machine include the rear springing device, which completely isolates the saddle and footboards from the remainder of the machine—a feature which has long been standard practice on Bat machines—and the Lucas Magdyno equipment. Five models in all will be produced next year, a solo and a sidecar machine with the clutch mounted on the gear box, and two similar machines with the rear wheel clutch, whilst the machine *de luxe* will be electrically equipped.

6 h.p. twin four-stroke MODEL: 76×85 mm. (770 c.c.); side-by-side valves; Amac carburetter; C.A.V. gear-driven magneto; three-speed sliding gear; chain drive.

The 6 h.p. Bat motor cycle is practically identical with its companion, the 8 h.p. model, the principal difference, of course, being the lower powered J.A.P. engine. Three models will be produced, fitted with the new rear detachable hub, two of which will be sidecar outfits, equipped with the Bat sidecar, which, it will be remembered, has a novel and highly efficient springing system. The remaining two models, a solo and sidecar machine, will retain the original rear wheel clutch, and will not be fitted with detachable and interchangeable wheels. A feature of both the 6 and 8 h.p. Bat models is the method of carrying the gear box, which is supported on a special subframe running from the rear wheel to the lower half of the crank case. Both machines also are finished in grey and have circular tanks. Several examples of Bat sidecars are displayed, and, perhaps, the most striking model is an entirely enclosed miniature limousine body.

A 2¼ h.p. two-stroke, the Vindec, marketed by Messrs. Brown Bros.



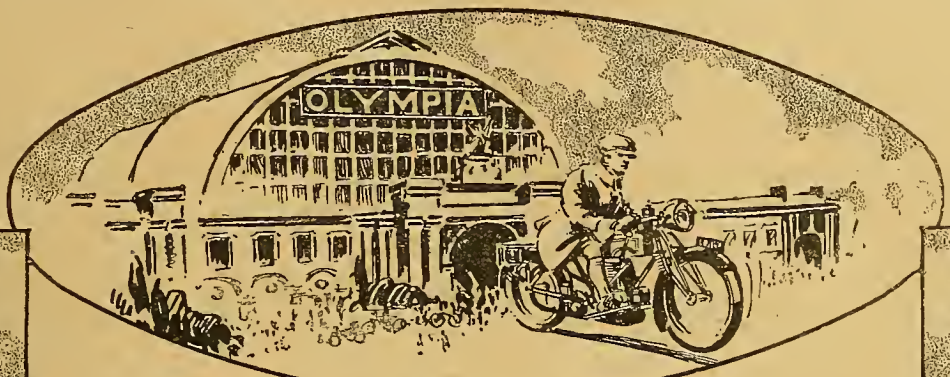


A novel machine at the Show which is attracting much attention and comment—the 8 h.p. Bat-Jap, with coupé sidecar.

VINDEC, No. 164.

2¼ h.p. two-stroke MODEL: 64×70 mm. (225 c.c); Amac carburetter; T.B. chain-driven magneto; two-speed gear; chain and belt drive; 24×2¼in. tyres.

BROWN BROS., LTD., Great Eastern Street, E.C.2.—Simplicity is the keynote of the Vindec layout, since a two-speed transmission is obtained without the use of a gear box. On each side of the crank case of the 2¼ h.p. two-stroke engine are chains driving countershaft sprockets of different diameters. These sprockets are connected to the shaft as desired by means of a sliding dog, and the final drive is by belt to the back wheel. The two-stroke engine is of the usual three-port type, and both engine and gear box are carried in a substantial loop frame. All old-time riders will be well acquainted with the name Vindec, and will be glad to see it carried on by Messrs. Brown Bros. at the present time by a lightweight machine well worthy of the reputation of its predecessors.



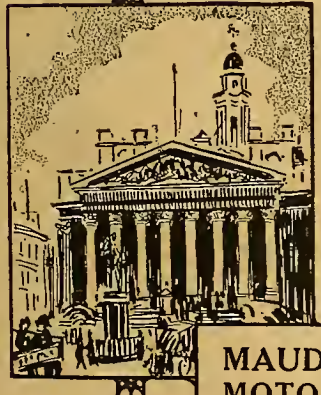
The Heart of the MOTOR-CYCLE WORLD

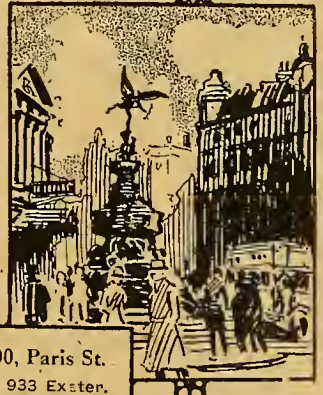
THOUGHTS of Olympia are thoughts of new machines—new ideas—new methods of construction. Old riders will contrast the early days with the present—new riders will find much to make their choice bewildering.

Maudes Motor Mart can assist both. There you will find skilled advice—honest dealing, and satisfaction—always.

We are large contractors of the following machines, and in many cases can give early delivery:—

A.B.C. BLACKBURNE. TRIUMPH. REX. ZENITH. MATCHLESS. B.S.A. HARLEY-DAVIDSON. CONNAUGHT. A.J.S. MORGAN. ALLDAYS. ARIEL. NEW IMPERIAL. BRADBURY. CLYNO. CHATER-LEA. ENFIELD. HUMBER. J.E.S. P. & M. NORTON. N.U.T. RUDGE. ROVER.





We are offering ROVER and NEW IMPERIAL Combinations at less than makers' prices:

New Imperial.—8 h.p. J.A.P. twin engine, 3-speed, clutch, all-chain drive, coachbuilt Sidecar, W.D., all-weather models.
Makers' Price - £144 18s.
Our Price - £135

Rover.—6 h.p. J.A.P. twin engine, 3-speed, clutch, chain drive, coachbuilt Sidecar, W.D., all-weather models.
Makers' Price - £188
Our Price - £125

THE SEAL OF SATISFACTION

A Private Owner's 12 Reasons for Riding a Sunbeam.

IN a recent competition in the *Auto Cycle Illustrated*, in which riders were asked to state reasons which influenced them in purchasing the machine which they ride, Lieut. J. A. NEWMAN obtained a prize, giving the following 12 reasons as to why he purchased a Sunbeam:—

(1) I have owned thirty-six machines, light weight, heavy weight, solo and sidecar, and I find that it is THE BEST.

(2) There is an old motto that "The best is the cheapest," and although the Sunbeam is the dearest machine on the market it is the cheapest to run, and fetches the highest prices, pro rata, second-hand.

(3) Transmission is Weatherproof, absolutely. There is no other machine on the market with such solid and perfectly made chain cases.

(4) It will take a Sidecar anywhere, and I mean ANYWHERE.

(5) The drive is absolutely smooth at the slowest speeds. None of the belt-driven machines, or Chain-cum-Belt, on the market are its equal in this respect.

(6) It is better for all-round work than a machine with two or more Cylinders, as less attention is required to keep it in Tune.

(7) It steers magnificently. I proved this in the recent Scottish Six Days where I won a Gold Medal.

(8) It climbs anything with total absence of Fuss.

(9) It is extremely silent.

(10) I can point out advantages on the Sunbeam single which no other Machine can claim in entirety.

(11) The bearings wear ALMOST INDEFINITELY.

(12) It starts perfectly, no injection or decompression device being needed. In regard to my claim that a 3½ single is the best machine for all-round purposes: it is the type which has been most consistently successful for many years. The only claim in favour of the flat twin is the smooth running. I maintain that no flat twin runs smoother than the 3½ Sunbeam. As regards a bigger engine, if the 3½ Sunbeam can do everything, why buy a machine of greater power?

STAND 49, OLYMPIA.

MAKERS:—

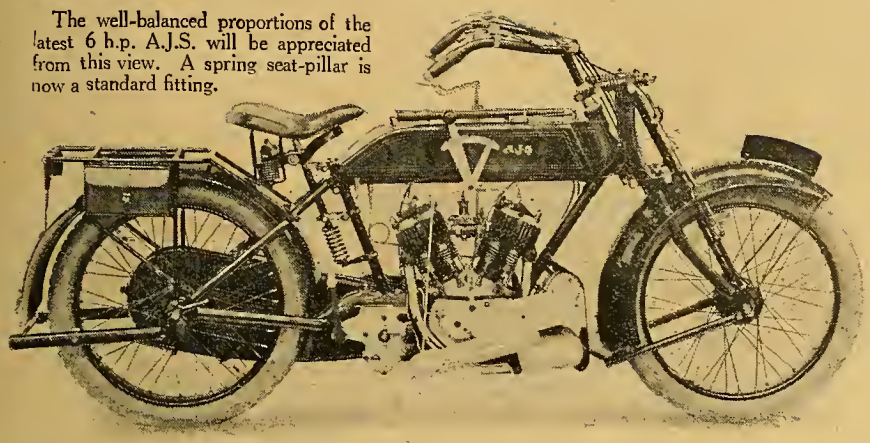
In answering this advertisement it is desirable to mention "The Motor Cycle."

The Olympia Show.—

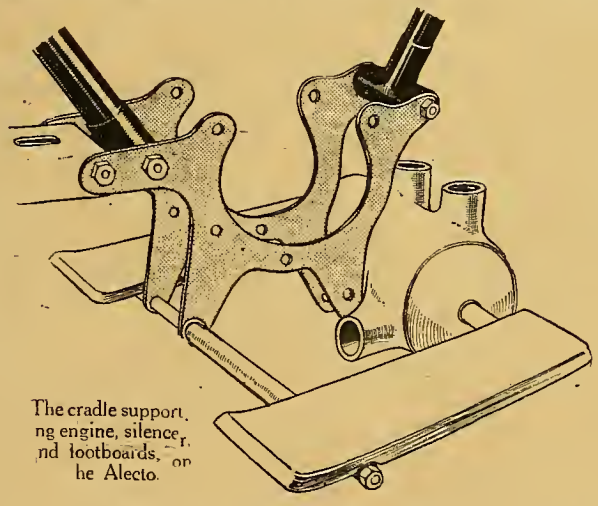
The well-balanced proportions of the latest 6 h.p. A.J.S. will be appreciated from this view. A spring seat-pillar is now a standard fitting.



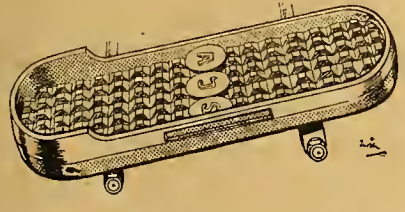
A.J.S., No. 31.

6 h.p. V twin four-stroke MODEL: 74×81 mm. (749 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett chain-driven magneto; three-speed sliding gear; chain drive; 700×80 mm. Dunlop tyres.

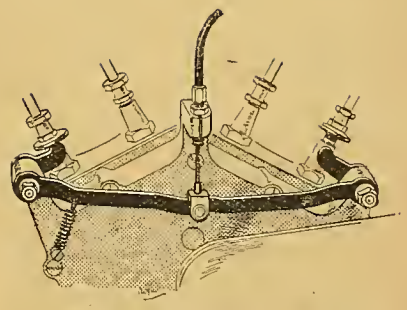
A. J. STEVENS AND CO. (1914), LTD., Penn Road, Wolverhampton.—One type only of A.J.S. is shown on this stand, which is the 6 h.p. sidecar outfit, one of the most practical and popular machines of its kind on the British market. It is full of interesting points. The careful student will note the width of the saddle-tank situated above the top tube of the frame, rendering it easy to clean. The width of the mudguards will be commended, whilst a very practical form of spring seat-pillar, in addition to the comfortable saddle fitted, absorbs all road shocks. The extra hand lever attached to one side of the back stand is another practical feature which enables the rider to put enormous leverage on to the stand and to raise the whole of the machine with the minimum amount of effort. All these models are fitted with the Amac single lever carburetter, concerning the working of which the designer is most enthusiastic. The footboards are rubber covered, with deep studs effectually absorbing any vibration that may be felt in the feet. The only variation in types is the fitting of electric light in the case of one model shown, which is equipped with a Lucas dynamo, driven by a Whittle belt neatly enclosed in a case, off the engine-shaft. The dynamo is eccentrically mounted in its housing, and if one of the holding-down bolts is loosened the whole dynamo may be twisted, and, by this means, any slack in the belt may be taken up. The switch controlling the lights is fitted to the side of the tank. No one can examine the A.J.S. machines exhibited without remarking upon their practical points and excellent finish throughout.



The cradle support, engine, silencer, and footboards, on the Alecto.



Extra deep rubber studs are a feature of the A.J.S. footboards.

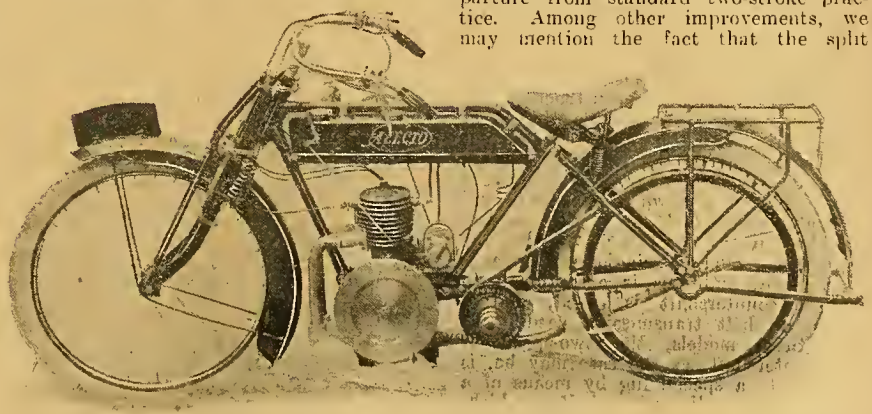


The centrally operated exhaust lifter mechanism on the A.J.S.

ALECTO, No. 15.

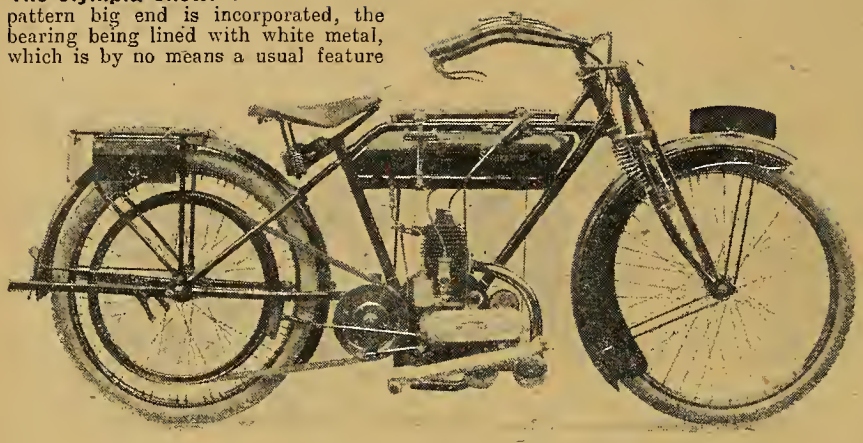
3½ h.p. two-stroke MODEL: 76×76 mm. (345 c.c.); Amac carburetter; C.A.V. magneto, chain driven; two-speed Burman sliding gear; chain-cum-belt drive; 26×2¼in. Dunlop tyres.

CASHMORE BROS., LTD., Hildreth Street, Balham, S.W.12.—Two solo motor bicycles are to be seen on this stand. The Alecto is a two-stroke which possesses several original features and many interesting points. Among these we may mention the twin system of exhaust pipes enteriog a large silencer, and the compression release connected up to the exhaust pipe so as to eliminate any objectionable noise. It is interesting to note that the silencer has three times the capacity of the cylinder; consequently the Alecto should be among the quietest of two-strokes. The latest model is now fitted with a handle-bar controlled magneto. Another special feature of this machine is the size of the radiating fins on the cylinder, which should render the engine very cool running. The piston is of an aluminium alloy known as Magnalium, possessing two rings, a compression ring and a scraper ring. This is one of the new firms which has developed since the war, and the fact probably accounts for the designers having incorporated the novel features, to which we have referred, which mark a departure from standard two-stroke practice. Among other improvements, we may mention the fact that the split



One of the newcomers, the 3½ h.p. Alecto, fitted with an engine of 350 c.c.

The Olympia Show.—



A two-speed model chain and belt-driven Sparkbrook. This is one of the best finished two-strokes in the Show.

pattern big end is incorporated, the bearing being lined with white metal, which is by no means a usual feature in motor cycle construction. The machine is finished in dark blue with red bands, and was described in the issue of *The Motor Cycle* of July 31st, 1919, page 112. Since that date one or two minor improvements have been incorporated; the rear brake is now controlled by the rider's toe instead of the heel, and sensibly wide handle-bars have been fitted.

SPARKBROOK, No. 77.

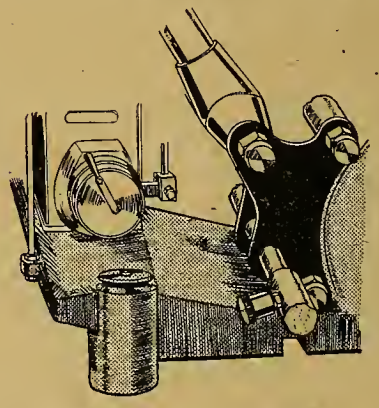
2½ h.p. single two-stroke MODEL: 70×70 mm. (269 c.c.); B. and B. carburetter; C.A.V. chain-driven magneto; two-speed gear; chain and belt drive; 26×2in. Dunlop tyres.

SPARKBROOK MANUFACTURING CO., LTD., Payne's Lane, Coventry.—For the forthcoming year, the Sparkbrook Co. have decided to market one main model only, and, by concentrating on this, their output, it is hoped, will be considerably increased. The Sparkbrook is one of the really high-class assembled two-strokes which are now obtainable. Fitted with a Villiers two-stroke engine and a two-speed countershaft gear of the company's own manufacture, it is an extremely neat and serviceable little mount. The detail work is excellent and the finish extremely taking. Few alterations have been made, but the following points are noticeable: The oil supply from a Best and Lloyd sight-feed is connected to a hollow engine bolt and passes to the crank by this means. A very serviceable and stoutly constructed heel brake operates a shoe inside the V of the belt rim, and thus the shoe does not get in the way of the rear wheel when the latter has to be detached. The stand also has been somewhat improved, and neat aluminium footboards with serviceable heel plates are fitted. Besides the two-speed model, a single-gear type is also shown, and this is exceptional, in that a countershaft is fitted, and a chain and belt transmission used. In both these models, the two-speed or the countershaft, as the case may be, is attached to a special lug by means of a single large diameter bolt, which, besides serving as a fixing, is utilised as a method of lubrication, being fitted at the top with a large oil cup. Touring and sporting models of each of the above types are staged complete.

REX, No. 55.

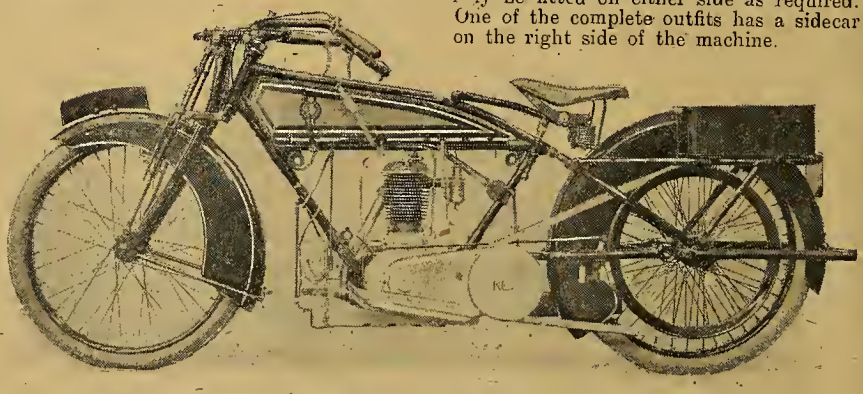
4 h.p. single four-stroke MODEL 77: 84.5×98 mm. (550 c.c.); side-by-side valves; Amac carburetter; M-L chain-driven magneto; Sturmey-Archer three-speed gear, chain and belt drive; 28×2½in. Dunlop tyres.

REX MOTOR MANUFACTURING CO., LTD., Earlsdon, Coventry.—The Rex will long remain in the memory of old motor cyclists as one of the pioneer makes which did so much to develop the industry at a time when it appeared to be in danger of becoming extinct by the apathy of manufacturers generally concerning motor cycles some fifteen years ago. The Rex reputation generally has been bound up more with twin-cylinder machines than with those of the single-cylinder type, and though the non-appearance of the twin-cylinder Rex at the Show has no doubt been a source of disapointment to twin enthusiasts, the new single-cylinder model should, on the other hand, go far to revive the Rex name in the world of first-class motor cycles. Unlike the majority of single cylinders the new Rex engine has mechanical lubrication carried out more or less on car lines. A large sump, which also forms a platform for the magneto, is part of the crank case, in which three pints of oil are carried, and this, in conjunction with the auxiliary oil compartment in the main tank, provides lubricant for approximately 500 miles. A worm-driven pump is fitted inside the sump, and may be removed complete, if necessary, by detaching six screws. Lubrication, in fact, appears to have been closely studied throughout the machine, and not least amongst the features of the framework may be mentioned the use of steel lugs and the large lubricator on the steering head. This forms part of the head lug, and has a duct to the lower ball race. The brake pedal lever also has a means of lubrication in the form of a screw-down grease cup, and the bearing which supports the separate belt wheel



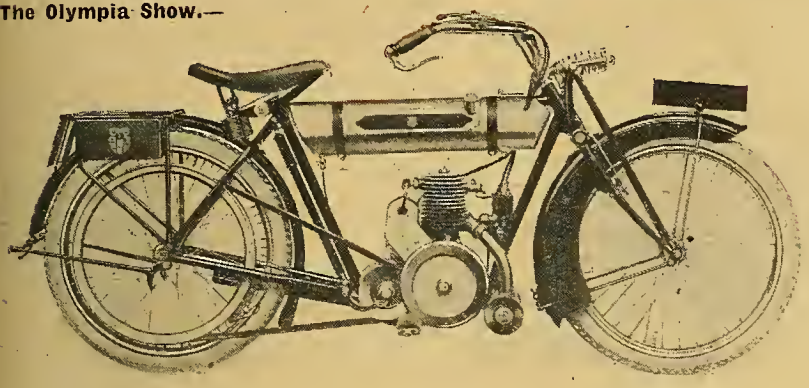
The new oil sump on the Rex outfit

is lubricated by means of a similar grease cup located at the extremity of the outside back stay. Large lubricators are also fitted to the wheels. A noteworthy point in the engine is that it is fitted with an aluminium alloy piston of the lantern pattern, and the roller bearing big end and mainshaft are supported on each side by a large sized ball bearing, the driving sprocket being further supported by a bearing of the roller type. The framework of the new Rex embodies integral sidecar lugs, which are of the parallel type and arranged so that the sidecar may be fitted on either side as required. One of the complete outfits has a sidecar on the right side of the machine.



The 4 h.p. double-purpose Rex single-cylinder machine, which is notable for its long wheelbase.

The Olympia Show.—



The 2¼ h.p. Junior Triumph two-stroke.

TRIUMPH, No. 96.

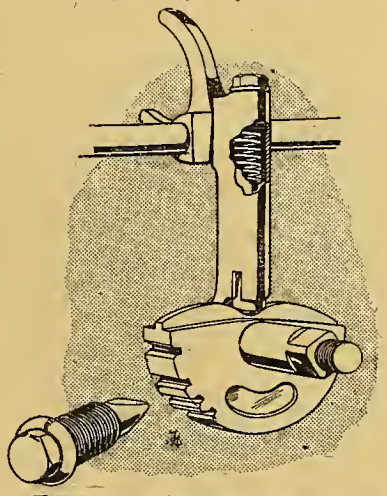
4 h.p. single four-stroke MODEL: 85×97 mm. (550 c.c.); side-by-side valves; Triumph carburetter; M-L chain-driven magneto; three-speed sliding gear; chain drive; 26×2½in. tyres.

TRIUMPH CYCLE CO., LTD., Coventry.—So far as the Show is concerned, all the four-stroke models seen on the Triumph stand are new, for it will be remembered that the 4 h.p. countershaft model, so extensively used by our D.R.'s in all parts of the world, was not to be seen when Olympia was last held. The two-stroke is familiar, and remains unaltered. The real feature of interest on this stand, however, is the new all-chain-driven model, known as the S.D. type, which so distinguished itself as a sidecar machine in the recent Six Days Trial. The general outlines of this machine closely follow those of the 4 h.p. chain-cum-belt model, and here for the first time we see a Triumph fitted with all-chain transmission, which has, as might be expected, been designed in a neat and yet workmanlike manner, in keeping with the Triumph standard.

The three-speed gear box is one of the Triumph Co.'s own design and manufacture, and is of the sliding pinion and dog type. An interesting point in the construction of the gear box is that no splines or keys are used for carrying sprockets, etc., these being held by projecting dogs formed on the main shaft. A quick thread shock-absorbing device is introduced, and is mounted on the gear box main shaft. The clutch is of a multi-plate friction type running in oil, and is controlled by means of Bowden control from the handle-bars. Simplicity throughout is undoubtedly the chief feature in all the Triumph models, even to the internal details. For instance, both valves are actuated from the one timing wheel; the well-known Triumph spring fork with its one moving joint is retained until the later enclosed spring type with its neat damping device can be manufactured in quantity. The general clean design of the machine is continually impressed upon one when examining this exhibit.

Both the 4 h.p. models are seen fitted to Gloria sidecars, which have been re-designed, having a spring wheel suspension which quite insulates the chassis from road shocks. For the first time sidecar lugs are incorporated in Triumph frames.

2¼ h.p. single two-stroke MODEL: 64×70 mm. (225 c.c.); Triumph carburetter; M-L chain-driven magneto; two-speed gear; chain and belt drive; 24×2¼in. tyres.



To prevent damage to gears when changing, a spring device is interposed between the control and striking fork in the latest Triumph gear box.

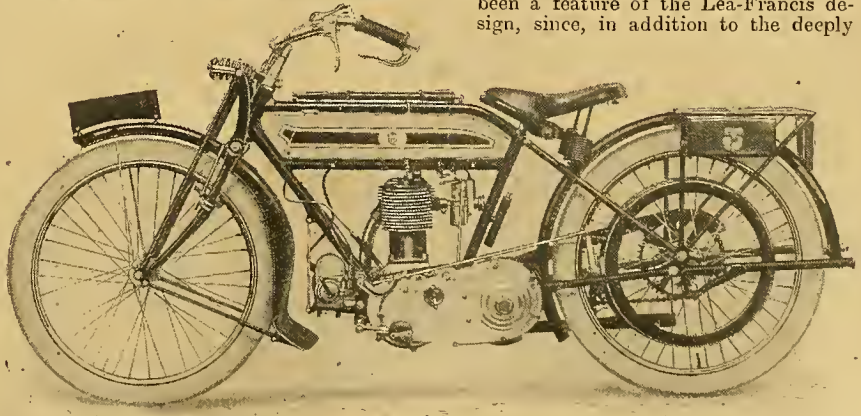
The Junior Triumph still has its two-speed gear box operated by handle-bar control—a point which must appeal to all beginners or nervous riders. Lubrication is by petroil, a small valve operated by a plunger allowing the oil to be removed from the oil tank for admixture with the petrol.

LEA and FRANCIS, No. 50.

3½ h.p. V twin four-stroke MODEL: J.A.P.; 70×64.5 mm. (494 c.c.); side-by-side valves; Amac carburetter; Thomson-Bennett chain-driven magneto; two-speed sliding gear; chain drive; Palmer Cord 26×2¾in. tyres.

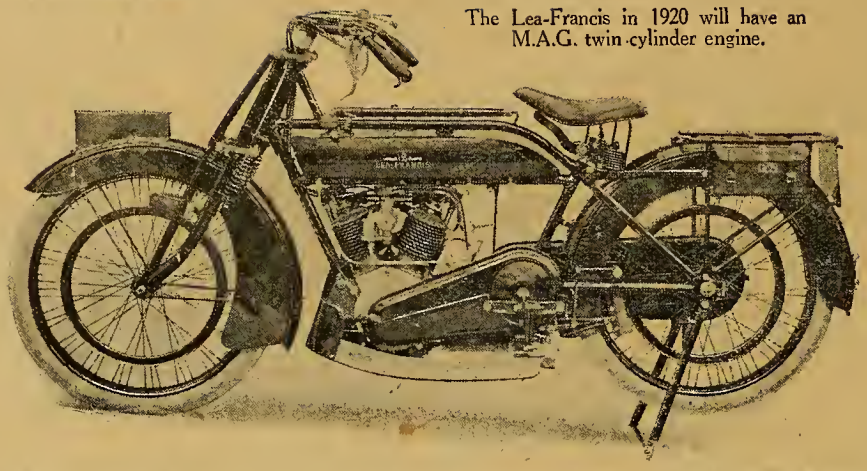
LEA AND FRANCIS, LTD., Lower Ford Street, Coventry.—The reappearance of the Lea-Francis motor cycle after a somewhat prolonged absence from the public view will be gratefully noticed by all interested in an essentially all-weather and reliable solo mount. In the first place, the makers adopted a design at once neat in outline, and tending to secure the above-mentioned qualities. Taken generally, the machine does not deviate to any great extent from the original layout, which proved its worth in the big trials of 1913 and 1914. Dealing first with the J.A.P.-engined model, the power unit is the 3½ h.p. twin, embodying the oiling system associated with that make, adjustable tappets, and a simple external exhaust lifter. The magneto is situated behind the engine, and is driven from the mainshaft, consequently the contact breaker is easily accessible on the off side. Transmission from engine to the detachable back wheel is by chain, through a two-speed constant mesh gear box, which is housed in a cylindrical bottom bracket housing. The final drive passes over to the right of the machine, and is enclosed in a compact case of the same depth from end to end. A multi-plate clutch is fitted with an ingenious arrangement of separate handle-bar and foot controls. Brakes on both front and rear wheels consist of V-shaped pads working inside dummy belt rims. This type of brake, as applied to front wheels, was originally introduced by the Lea-Francis firm, and a glance round the Show indicates how largely this system has been followed by other designers. A large silencer, connected to the cylinder by flexible exhaust pipes, accounts for the silence of this machine on the road.

Excellent mudguarding has always been a feature of the Lea-Francis design, since, in addition to the deeply



A newly designed three-speed gear and all-chain transmission are the chief alterations on the 1920 model 4 h.p. Triumph.

The Olympia Show.—



The Lea-Francis in 1920 will have an M.A.G. twin-cylinder engine.

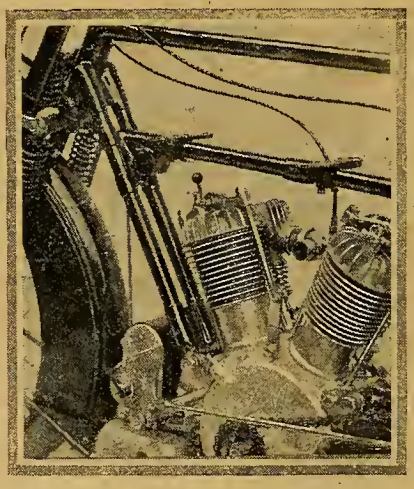
valanced front guard, there is a screen across the front of the footboards which adequately protects the engine and the feet of the rider. Details worthy of attention are the neat inspection holes in the chain cases covered by small discs (similar to contact breaker covers), held in place by flat springs, the metal tubes through which the high-tension wires are led, and the method of adjusting the front chain by rotating the gear box in its shell. The points just mentioned serve to show the care displayed by the designer in adapting the machine to the requirements of the practical motor cyclist.

The second model is engined with the V twin M.A.G. unit. This has overhead inlet valves, which, with their cages and tappet rods, are completely enclosed. By this arrangement, the whole valve mechanism may be lubricated by oil spray from the crank case, and this causes the engine to be noticeably free from the mechanical noise and clatter often associated with overhead inlet valves. On general lines, the specification follows that of the model already described.

BRADBURY, No. 52.

2¾ h.p. single four-stroke MODEL: 74.5×80 mm. (349 c.c.); side-by-side valves; B. and B. carburetter; magneto, chain driven; two-speed constant mesh gear; chain-cum-belt drive; 26×2¼in. tyres.

BRADBURY AND CO., LTD., Wellington Works, Oldham.—Undoubtedly one of the most attractive solo propositions in the Show of the single-cylinder type is the new 2¾ h.p. Bradbury. The engine is of a size which a large number of riders consider ideal for solo work, *i.e.*, 350 c.c., and the new Bradbury reminds one very much of a 3½ h.p. countershaft model slightly cut down in engine size. Everything on the machine appears to be of excellent quality and finish, and is produced throughout in the Bradbury factory. The frame is of duplex construction at the front, and embodies the commendable Bradbury feature of forming the crank case as a nucleus of the frame. The main portion of the crank case is a malleable iron casting, and upon the side is bolted an aluminium cover plate embodying the timing case and the inner side of the magneto chain case. This form of construction provides rigidity, eliminating, as it does, the use of engine plates. From the seat tube to the rear of the gear box bracket an auxiliary member is fitted,



Note the duplex down tube and detachable tank platforms of the 1920 6 h.p. Bradbury.

which forms a small triangle to which the gear box is attached. The tank, finished in the growingly popular gold and black, has rounded sides, and tapers to the rear. The two-speed gear differs from the majority, inasmuch as the cork inset clutch is embodied in the engine pulley. A kick-starter is fitted on the right side of the machine, as in the case of the 6 h.p. model. Druid Mark II. forks, Brooks saddle, aluminium footboards, and the usual tool-box are included in the specification. The price of this mount is £85.

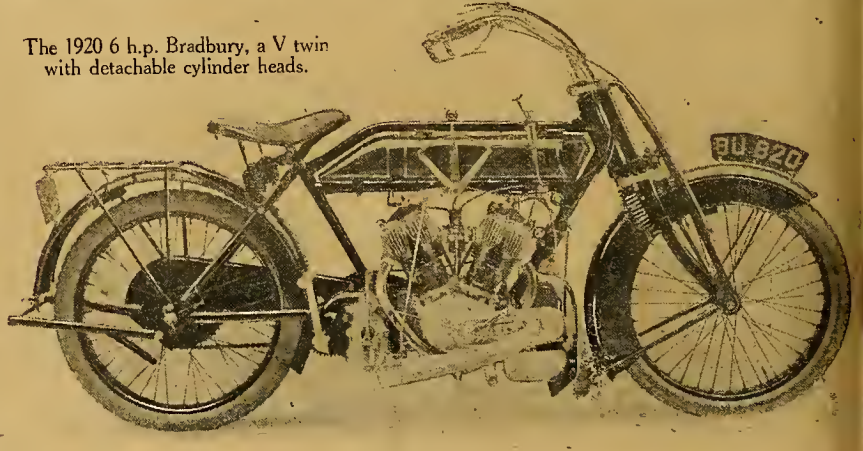
6 h.p. V twin four-stroke MODEL: 74.5×86 mm. (750 c.c.); side-by-side valves; B. and B. carburetter; magneto, chain driven; three-speed sliding gear; chain drive; 650×65 mm. Dunlop tyres.

The leading Bradbury mount is the 6 h.p. V twin, much after the lines of the pre-war model, but improved in many details. Detachable cylinder heads are used, secured by two long bolts fore and aft of the cylinder and a yoke which bears on the cylinder head at two points. The adjustable tappets have large heads, and are offset to the valve stems. Installed behind the engine is a three-speed countershaft gear box, which has enclosed kick-starter mechanism. The machine presents a workmanlike appearance, the efficient magneto shield and large aluminium footplates being worthy of special mention. Unlike most similar machines, both the primary and secondary chains are protected only by a top guard, a point of design favoured by many riders who have suffered a chain breakage. The hub of the rear wheel is of the quick detachable type, and when removed the transmission and internal expanding brake remain undisturbed. A Grindlay double sprung sidecar is a standard attachment used by Messrs. Bradbury and Co. on this model, and the complete outfit will make a wide appeal. The price of the machine without sidecar is £122 10s.

4 h.p. single four-stroke MODEL: 89×89 mm. (554 c.c.); side-by-side valves; B. and B. carburetter; T.B. magneto, chain driven; three-speed sliding gear; chain drive; 26×2¾in. Dunlop tyres.

This model was one of the favourite single-cylinder machines for sidecar work before the war, and it is not surprising that Messrs. Bradbury and Co. have reintroduced it for the 1920 season. It may be recalled that it was on this machine that Mr. Hugh Gibson put up some wonderful performances at a time

The 1920 6 h.p. Bradbury, a V twin with detachable cylinder heads.



The Olympia Show.—

When the general public was doubtful concerning the suitability of the type for sidecar work. Very few alterations have been made in the model shown at Olympia, and consist chiefly of refinements in detail. The tank, like the 2¾ h.p. model, has rounded sides and tapers to the rear. The equipment is similar to that of the smaller model, only, of course, everything is so much larger. As on the twin model, the rear brake is of the internal expanding type.

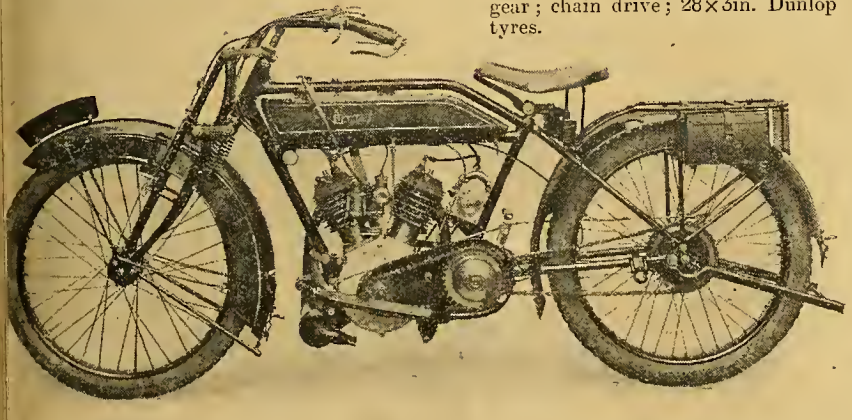
DOT, No. 113.

8 h.p. V twin MODEL: 85.5×85 mm. (976 c.c.); side-by-side valves; Amac carburetter; E.I.C. chain-driven magneto; three-speed sliding gear; chain drive; Dunlop 26×3in. tyres.

DOT MOTORS, 38, Ellesmere Street, Hulme, Manchester.—A noticeable feature of this sidecar model is the design and generous dimensions of the pedal-operated rear wheel brake. It is of the internal-expanding type with a drum 8in. in diameter and 1¼in. wide; the adjustment is external and peculiarly accessible. The machine is shown attached to an exceptionally roomy sidecar, the upholstery of which is in imitation pigskin, while the outfit as a whole, like the other exhibits on this stand, is finished in red. The sidecar has a capacious box in the bulbous rear portion with a large lock-fitted lid. The suspension is by means of C springs fore and aft, while the four stays for attachment are brought to three points on the frame of the cycle, the two central tubular members, leading from the lower tube of the chassis, being carried to a lug below the saddle tube clip. All the lugs are integral with the frame of the machine, which is fitted with Saxon spring forks. The mudguarding should be particularly effective, for the front guard is 5¼in. wide, the sidecar wing 13in., and the driving wheel guard 6¾in., including the flat side extensions.

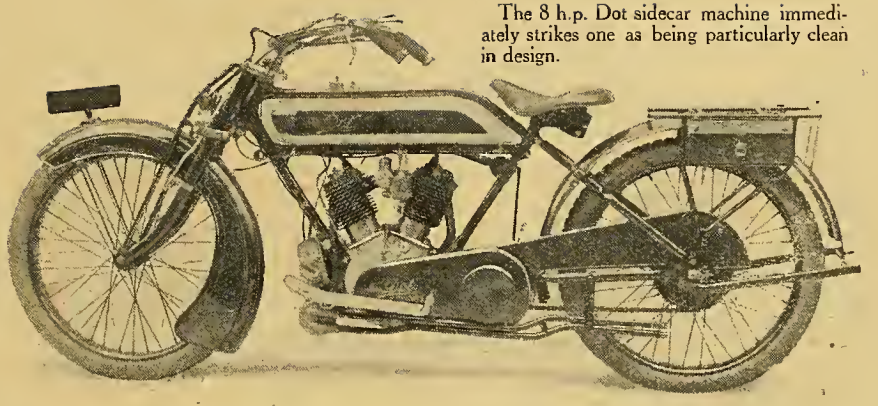
2¾ h.p. single MODEL: 70×76 mm. (292 c.c.); side-by-side valves; Amac carburetter; two-speed constant mesh gear; 26×2in. tyres.

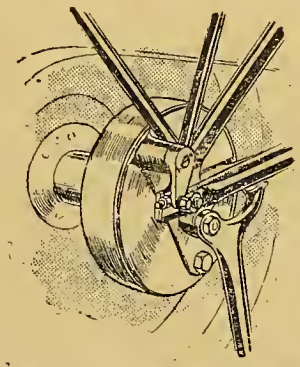
Two examples of this solo model are shown, one with semi-T.T. and the other with upturned handle-bars. The latter has an Albion gear with kick-starter and hand-controlled clutch; both have Saxon spring forks. The rear brake, pedal-operated, actuates within the belt rim, and is provided with a pivot pin anchored in a slotted lug so that the most effective angle of pad can be maintained when belt adjustments must be made; this slotted fixture is additional to the usual adjustment on the actual rod between pedal and shoe.



The 3½ h.p. James—a solo twin of 500 c.c.—with the Renold chain guard removed.

The 8 h.p. Dot sidecar machine immediately strikes one as being particularly clean in design.



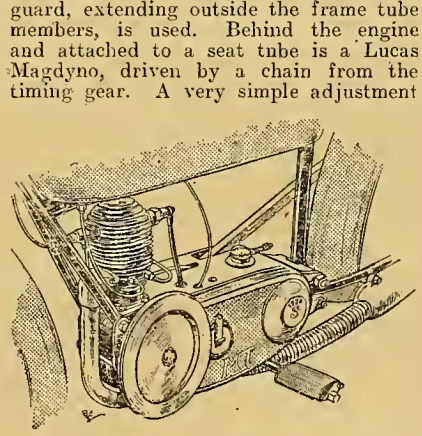


The 1920 8 h.p. Dot has an internal expanding brake in the rear hub.

JAMES, No. 71.

5·6 h.p. V twin four-stroke MODEL: 70×76 mm. (662 c.c.); side-by-side valves; Amac carburetter; chain-driven magneto; three-speed gear; chain drive; 28×3in. Dunlop tyres.

JAMES CYCLE CO., LTD., Greet, Birmingham.—The James Cycle Co. stage several interesting models, but the 5·6 h.p. will be dealt with first, as it is the most recently produced. The engine is a 50° twin-cylinder, having the usual distinctive James radiating fins. Transmission from the engine to the gear box and thence to the rear wheel is by totally enclosed chains. The gear box is a special three-speed countershaft gear of the firm's own manufacture, and the rear wheel has an internal expanding brake, operated by a pedal on the left-hand side of the engine. The clutch also is operated by a pedal on the opposite side. The front mudguard is fully valanced, and a very wide rear mudguard, extending outside the frame tube members, is used. Behind the engine and attached to a seat tube is a Lucas Magdyno, driven by a chain from the timing gear. A very simple adjustment



On the Metro-Tyler the magneto and gear box are totally enclosed.
